tensorModFreemod(M,F);
⇒ cokernel | 0 0 0 x 0 0 -y 0 0 |
⇒          | 0 0 0 0 x 0 0 -y 0 |
⇒          | 0 0 0 0 0 x 0 0 -y |
⇒          | y 0 0 0 0 0 x 0 0 |
⇒          | 0 y 0 0 0 0 0 x 0 |
⇒          | 0 0 y 0 0 0 0 0 x |
⇒
⇒
```

D.4.15.40 tensorFreemodMod

Procedure from library `modules.lib` (see [Section D.4.15 \[modules.lib\], page 1124](#)).

D.4.15.41 tensorFreeModule

Procedure from library `modules.lib` (see [Section D.4.15 \[modules.lib\], page 1124](#)).

Return: Tensorprodukt of M,N

Example:

```
LIB "modules.lib";
ring R = 0,(x,y,z),dp;
FreeModule F = freeModule(R,3,0);
F;
⇒ 3
⇒ R
⇒ free Module
⇒ Degrees of the generators: {0} {0} {0}
⇒
```

```

tensorFreeModule(F,F);
↳ 9
↳ R
↳ free Module
↳

```

D.4.15.42 tensorProduct

Procedure from library `modules.lib` (see [Section D.4.15 \[modules.lib\]](#), page 1124).

D.4.15.43 pruneModule

Procedure from library `modules.lib` (see [Section D.4.15 \[modules.lib\]](#), page 1124).

Return: M in a simplified presentation

Example:

```

LIB "modules.lib";
ring R = 0,(x,y,z),dp;
matrix a[2][3] = -x,-y^2,x^3,y,x,0;
matrix b[1][2] = x^2-y^3,xy;
Matrix A = a;
Matrix B = b;
Module M = coker(A);
Module N = coker(B);
Module H = hom(M,N);
H;
↳ subquotient (| 0 -y -y 0 -x |, | -y3+x2 xy 0 0 |)
↳ | xy -x -x y3 -y2 | | 0 0 -y3+x2 xy |
↳
↳
pruneModule(H);
↳ cokernel | 0 y2 x2 x |
↳ | x 0 0 y3 |
↳
↳

```

D.4.15.44 hom

Procedure from library `modules.lib` (see [Section D.4.15 \[modules.lib\]](#), page 1124).

Return: calculates $\text{Hom}(M,N)$ as a subquotient and yields an interpretation for the elements

Example:

```

LIB "modules.lib";
"Example:";
↳ Example:
ring R = 0,(x,y,z),dp;
matrix a[2][3] = -x,-y^2,x^3,y,x,0;
matrix b[1][2] = x^2-y^3,xy;
Matrix A = a;
Matrix B = b;
Module M = coker(A);
Module N = coker(B);
hom(M,N);

```

```

⇒ subquotient (| 0  -y -y 0  -x  |, | -y3+x2 xy 0      0  |)
⇒              | xy -x -x y3 -y2 | | 0      0  -y3+x2 xy |
⇒
⇒

```

D.4.15.45 kerHom

Procedure from library `modules.lib` (see [Section D.4.15 \[modules.lib\]](#), page 1124).

Return: returns the kernel of the given homomorphism

Example:

```

LIB "modules.lib";
ring R=0,(x,y),(lp,c);
Matrix M=id(2);
Module src=image(M);
matrix rules[2][2]=x,y,xy,y2;
Module tar=coker(M);
Homomorphism f=homomorphism(rules,src,tar);
f;
⇒ | x  y  |
⇒ | xy y2 |
⇒
⇒ cokernel | 1 0 | <--- R^2
⇒          | 0 1 |
⇒
kerHom(f);
⇒ image | 0  -1 |
⇒       | -1 0  |
⇒
⇒

```

D.4.15.46 interpret

Procedure from library `modules.lib` (see [Section D.4.15 \[modules.lib\]](#), page 1124).

Return: interpretation of V into some space that is stored in the interpretationlist of V .space

Example:

```

LIB "modules.lib";
"example 1:";
⇒ example 1:
ring R = 0,(x,y),dp;
matrix a[1][2] = x,y;
Matrix A = a;
matrix b[1][2] = x2,y2;
Matrix B = b;
Module M = subquotient(A,B);
Module C = presentation(M);
Vector V = [x2,y4],C;
interpret(V);
⇒ | y5+x3 |
⇒
⇒
"example 2:";

```

```

↳ example 2:
ring S;
matrix gens[2][3] = x2+y-3z4,y+xy,xyz+4,3+z2x,z3-3x+3,2+x+y+z7;
vector v = 2x*[gens[1..2,1]] + (y-z2)*[gens[1..2,2]] + 5*[gens[1..2,3]];
Matrix Gens = gens;
M = subquotient(Gens,zero(2,3));
M.interpretation = list(list(1,1,1),list());
V = v,M;
interpret(V);
↳ -z2+2x+y+5

```

D.4.15.47 interpretInv

Procedure from library `modules.lib` (see [Section D.4.15 \[modules.lib\]](#), page 1124).

Return: interpretation of V into some Module N (inverse to `interpret`)

Example:

```

LIB "modules.lib";
ring R;
matrix gens[2][3] = x2,xy,4,z2x,3x+3,z;
vector v = 2x*[gens[1..2,1]] + (y-z2)*[gens[1..2,2]] + 5*[gens[1..2,3]];
Matrix Gens = gens;
Module S = subquotient(Gens,zero(2,3));
Module N = coker(id(3));
matrix E = N.generators.hom;
Vector E1 = [1,0,0],N;
Vector E2 = [0,1,0],N;
Vector E3 = [0,0,1],N;
S.interpretation = list(list(E1,E2,E3),list([gens[1..2,1]], [gens[1..2,2]], [gens[1..2,3]]));
Vector V = v,S;
Vector W = interpret(V),N;
net(V);
↳ | -xyz2+2x3+xy2+20 |
↳ | 2x2z2-3xz2+3xy-3z2+3y+5z |
↳
Vector Vnew = interpretInv(W,S);
net(Vnew);
↳ | -xyz2+2x3+xy2+20 |
↳ | 2x2z2-3xz2+3xy-3z2+3y+5z |
↳
V==Vnew;
↳ 1

```

D.4.15.48 reduceIntChain

Procedure from library `modules.lib` (see [Section D.4.15 \[modules.lib\]](#), page 1124).

Return: Module C with minimized (or # steps) interpretation list

Example:

```

LIB "modules.lib";
ring R;
matrix a[5][4];
Module M = coker(a+1);

```

```
Module N = simplePrune(simplePrune(simplePrune(simplePrune(M))));
//reduceIntChain(N);
```

D.4.15.49 interpretElem

Procedure from library `modules.lib` (see [Section D.4.15 \[modules.lib\]](#), page 1124).

Return: interpretation of a Vector with # steps or until can't interpret further

Example:

```
LIB "modules.lib";
ring R;
matrix a[5][4];
Module M = coker(a+1);
Module N = simplePrune(simplePrune(simplePrune(simplePrune(M))));
Vector V = [x+y],N;
interpretElem(V,3);
⇒ | 0 |
⇒ | 0 |
⇒ | 0 |
⇒ | x+y |
⇒
⇒
```

D.4.15.50 interpretList

Procedure from library `modules.lib` (see [Section D.4.15 \[modules.lib\]](#), page 1124).

Return: interpretation of Elements in some abstract structure defined by the user or into a Module

Example:

```
LIB "modules.lib";
ring R;
matrix a[5][4];
Module M = coker(a+1);
Module N = simplePrune(simplePrune(simplePrune(simplePrune(M))));
Vector V = [x+y],N;
Vector W = [x2+y2+3*z2],N;
Vector U = [x+2y+27z],N;
list L = U,V,W;
//interpretList(L,3);
```

D.4.15.51 compareVectors

Procedure from library `modules.lib` (see [Section D.4.15 \[modules.lib\]](#), page 1124).

Usage: `compareVector(V1,V2);` Vector V1,V2

Return: compares the given Vectors up to equivalence

Example:

```
LIB "modules.lib";
ring r;
matrix m[2][1] = x,-y;
Module M = subquotient(id(2),m);
```

```

Vector V = [x,y],M;
Vector W = [0,2y],M;
Vector U = [x,y2],M;
compareVectors(V,W);
↦ 1
compareVectors(U,V);
↦ 0

```

D.4.15.52 simplePrune

Procedure from library `modules.lib` (see [Section D.4.15 \[modules.lib\]](#), page 1124).

Return: Simplified Module with reduced dimension

Example:

```

LIB "modules.lib";
ring R;
matrix a[5][4];
Module M = coker(a+1);
Module N = simplePrune(M);

```

D.4.16 modstd.lib

Library: `modstd.lib`

Purpose: Groebner bases of ideals/modules using modular methods

Authors: A. Hashemi Amir.Hashemi@lip6.fr
 G. Pfister pfister@mathematik.uni-kl.de
 H. Schoenemann hannes@mathematik.uni-kl.de
 A. Steenpass steenpass@mathematik.uni-kl.de
 S. Steidel steidel@mathematik.uni-kl.de

Overview: A library for computing Groebner bases of ideals/modules in the polynomial ring over the rational numbers using modular methods.

References:

E. A. Arnold: Modular algorithms for computing Groebner bases. *J. Symb. Comp.* 35, 403-419 (2003).
 N. Idrees, G. Pfister, S. Steidel: Parallelization of Modular Algorithms. *J. Symb. Comp.* 46, 672-684 (2011).

Procedures:

D.4.16.1 modStd

Procedure from library `modstd.lib` (see [Section D.4.16 \[modstd.lib\]](#), page 1148).

Usage: `modStd(I[, exactness]);` I ideal/module, exactness int

Return: a standard basis of I

Note: The procedure computes a standard basis of I (over the rational numbers) by using modular methods.

An optional parameter 'exactness' can be provided. If `exactness = 1`(default), the procedure computes a standard basis of I for sure; if `exactness = 0`, it computes a standard basis of I with high probability.

Example:

```

LIB "modstd.lib";
ring R1 = 0, (x,y,z,t), dp;
ideal I = 3x3+x2+1, 11y5+y3+2, 5z4+z2+4;
ideal J = modStd(I);
J;
↪ J[1]=x3+1/3x2+1/3
↪ J[2]=z4+1/5z2+4/5
↪ J[3]=y5+1/11y3+2/11
I = homog(I, t);
J = modStd(I);
J;
↪ J[1]=x3+1/3x2t+1/3t3
↪ J[2]=z4+1/5z2t2+4/5t4
↪ J[3]=y5+1/11y3t2+2/11t5
ring R2 = 0, (x,y,z), ds;
ideal I = jacob(x5+y6+z7+xyz);
ideal J = modStd(I, 0);
J;
↪ J[1]=xy+7z6
↪ J[2]=xz+6y5
↪ J[3]=yz+5x4
↪ J[4]=x5-7/5z7
↪ J[5]=y6-7/6z7
↪ J[6]=z8
ring R3 = 0, x(1..4), lp;
ideal I = cyclic(4);
ideal J1 = modStd(I, 1); // default
ideal J2 = modStd(I, 0);
size(reduce(J1, J2));
↪ 0
size(reduce(J2, J1));
↪ 0

```

See also: [Section D.2.6.1 \[modular\]](#), page 884.

D.4.16.2 modGB

Procedure from library `modstd.lib` (see [Section D.4.16 \[modstd.lib\]](#), page 1148).

Usage: `modGB(method, I[, exactness])`; I ideal/module, exactness int method can be: std, slimgb, sba

Return: a standard basis of I

Note: The procedure computes a standard basis of I (over the rational numbers) by using modular methods.

An optional parameter 'exactness' can be provided. If `exactness = 1`(default), the procedure computes a standard basis of I for sure; if `exactness = 0`, it computes a standard basis of I with high probability.

Example:

```

LIB "modstd.lib";
ring R1 = 0, (x,y,z,t), dp;
ideal I = 3x3+x2+1, 11y5+y3+2, 5z4+z2+4;

```

```

ideal J = modGB("slimgb",I);
J;
↪ J[1]=x3+1/3x2+1/3
↪ J[2]=z4+1/5z2+4/5
↪ J[3]=y5+1/11y3+2/11
I = homog(I, t);
J = modGB("slimgb",I);
J;
↪ J[1]=x3+1/3x2t+1/3t3
↪ J[2]=z4+1/5z2t2+4/5t4
↪ J[3]=y5+1/11y3t2+2/11t5
ring R3 = 0, x(1..4), lp;
ideal I = cyclic(4);
ideal J1 = modGB("slimgb",I, 1); // default
ideal J2 = modGB("slimgb",I, 0);
size(reduce(J1, J2));
↪ 0
size(reduce(J2, J1));
↪ 0

```

See also: [Section D.2.6.1 \[modular\]](#), page 884.

D.4.16.3 modSyz

Procedure from library `modstd.lib` (see [Section D.4.16 \[modstd.lib\]](#), page 1148).

Usage: `modSyz(I);` I ideal/module

Return: a generating set of syzygies of I

Note: The procedure computes a the syzygy module of I (over the rational numbers) by using modular methods with high probability. The property of being a syzygy is tested.

Example:

```

LIB "modstd.lib";
ring R1 = 0, (x,y,z,t), dp;
ideal I = 3x3+x2+1, 11y5+y3+2, 5z4+z2+4;
modSyz(I);
↪ _[1]=z4*gen(1)-3/5x3*gen(3)-1/5x2*gen(3)+1/5z2*gen(1)-1/5*gen(3)+4/5*gen(\
1)
↪ _[2]=y5*gen(1)-3/11x3*gen(2)+1/11y3*gen(1)-1/11x2*gen(2)-1/11*gen(2)+2/11\
*gen(1)
↪ _[3]=y5*gen(3)-5/11z4*gen(2)+1/11y3*gen(3)-1/11z2*gen(2)+2/11*gen(3)-4/11\
*gen(2)
simplify(syz(I),1);
↪ _[1]=z4*gen(1)-3/5x3*gen(3)-1/5x2*gen(3)+1/5z2*gen(1)-1/5*gen(3)+4/5*gen(\
1)
↪ _[2]=y5*gen(1)-3/11x3*gen(2)+1/11y3*gen(1)-1/11x2*gen(2)-1/11*gen(2)+2/11\
*gen(1)
↪ _[3]=y5*gen(3)-5/11z4*gen(2)+1/11y3*gen(3)-1/11z2*gen(2)+2/11*gen(3)-4/11\
*gen(2)

```

See also: [Section D.2.6.1 \[modular\]](#), page 884.

D.4.16.4 modIntersect

Procedure from library `modstd.lib` (see [Section D.4.16 \[modstd.lib\]](#), page 1148).

Usage: `modIntersect(I,J);` I,J ideal/module
Return: a generating set of the intersection of I and J
Note: The procedure computes a the intersection of I and J
 (over the rational numbers) by using modular methods
 with high probability.
 No additional tests are performed.

Example:

```
LIB "modstd.lib";
ring R1 = 0, (x,y,z,t), dp;
ideal I = 3x3+x2+1, 11y5+y3+2, 5z4+z2+4;
ideal J = maxideal(2);
modIntersect(I,J);
↪ _[1]=z4-12/5x3-4/5x2+1/5z2
↪ _[2]=x3t2+1/3x2t2+1/3t2
↪ _[3]=x3zt+1/3x2zt+1/3zt
↪ _[4]=x3yt+1/3x2yt+1/3yt
↪ _[5]=x4t+1/3x3t+1/3xt
↪ _[6]=x3z2+1/3x2z2+1/3z2
↪ _[7]=x3yz+1/3x2yz+1/3yz
↪ _[8]=x4z+1/3x3z+1/3xz
↪ _[9]=y5-6/11x3+1/11y3-2/11x2
↪ _[10]=x3y2+1/3x2y2+1/3y2
↪ _[11]=x4y+1/3x3y+1/3xy
↪ _[12]=x5+1/3x4+1/3x2
simplify(intersect(I,J),1);
↪ _[1]=z4-12/5x3-4/5x2+1/5z2
↪ _[2]=x3t2+1/3x2t2+1/3t2
↪ _[3]=x3zt+1/3x2zt+1/3zt
↪ _[4]=x3yt+1/3x2yt+1/3yt
↪ _[5]=x4t+1/3x3t+1/3xt
↪ _[6]=x3z2+1/3x2z2+1/3z2
↪ _[7]=x3yz+1/3x2yz+1/3yz
↪ _[8]=x4z+1/3x3z+1/3xz
↪ _[9]=y5-6/11x3+1/11y3-2/11x2
↪ _[10]=x3y2+1/3x2y2+1/3y2
↪ _[11]=x4y+1/3x3y+1/3xy
↪ _[12]=x5+1/3x4+1/3x2
```

See also: [Section D.2.6.1 \[modular\]](#), page 884.

D.4.17 monomialideal_lib

Library: `monomialideal.lib`
Purpose: Primary and irreducible decompositions of monomial ideals
Authors: I.Bermejo, ibermejo@ull.es
 E.Garcia-Llorente, evgarcia@ull.es
 Ph.Gimenez, pgimenez@agt.uva.es
Overview: A library for computing a primary and the irreducible decompositions of a monomial ideal using several methods.
 In this library we also take advantage of the fact that the ideal is monomial to make some computations that are Grobner free in this case (radical, intersection, quotient...).

Procedures:**D.4.17.1 isMonomial**

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\], page 1151](#)).

Usage: `isMonomial (I)`; I ideal.

Return: 1, if I is monomial ideal; 0, otherwise.

Assume: I is an ideal of the basering.

Example:

```
LIB "monomialideal.lib";
ring R = 0,(w,x,y,z,t),lp;
ideal I = w^3*x*y, w^2*x^2*y^2*z^2 - y^3*z+x^4*z^4*t^4, w*x*y*z*t - w*x^6*y^5*z^4, x^2*y^3;
isMonomial(I);
↳ 1
ideal J = w^3*x*y + x^3*y^9*t^3, w^2*x^2*y^2*z^2 - y^3*z, w*x*y*z*t - w*x^6*y^5*z^4, x^2*y^3;
isMonomial(J);
↳ 0
```

D.4.17.2 minbaseMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\], page 1151](#)).

Usage: `minbaseMon (I)`; I ideal.

Return: an ideal, the minimal monomial generators of I.
(-1 if the generators of I are not monomials)

Assume: I is an ideal generated by a list of monomials of the basering.

Example:

```
LIB "monomialideal.lib";
ring R = 0,(w,x,y,z,t),lp;
ideal I = w^3*x*y, w^2*x^2*y^2*z^2, y^3*z,x^4*z^4*t^4, w*x*y*z*t,w*x^6*y^5*z^4, x^2*y^3;
minbaseMon(I);
↳ _[1]=w3xy
↳ _[2]=y3z
↳ _[3]=wxyz
↳ _[4]=x2z4t3
↳ _[5]=x2y2z2
```

D.4.17.3 gcdMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\], page 1151](#)).

Usage: `gcdMon (f,g)`; f,g polynomials.

Return: a monomial, the greatest common divisor of f and g.

Assume: f and g are monomials of the basering.

Example:

```
LIB "monomialideal.lib";
ring R = 0,(x,y,z,t),dp;
poly f = x^3*z^5*t^2;
poly g = y^6*z^3*t^3;
gcdMon(f,g);
↳ z3t2
```

D.4.17.4 lcmMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\]](#), page 1151).

Usage: `lcmMon (f,g)`; f, g polynomials.

Return: a monomial, the least common multiple of f and g .

Assume: f, g are monomials of the basering.

Example:

```
LIB "monomialideal.lib";
ring R = 0, (x,y,z,t), dp;
poly f = x^3*z^5*t^2;
poly g = y^6*z^3*t^3;
lcmMon(f,g);
↪ x3y6z5t3
```

D.4.17.5 membershipMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\]](#), page 1151).

Usage: `membershipMon(f,I)`; f polynomial, I ideal.

Return: 1, if f lies in I ; 0 otherwise.
(-1 if I and f are nonzero and I is not a monomial ideal)

Assume: I is a monomial ideal of the basering.

Example:

```
LIB "monomialideal.lib";
ring R = 0, (w,x,y,z,t), lp;
ideal I = w*x, x^2, y*z*t, y^5*t;
poly f = 3*x^2*y + 6*t^5*z*y^6 - 4*x^2 + 8*w*x^5*y^6 - 10*y^10*t^10;
membershipMon(f,I);
↪ 1
poly g = 3*w^2*t^3 - 4*y^3*z*t^3 - 2*x^2*y^5*t + 4*x*y^3;
membershipMon(g,I);
↪ 0
```

D.4.17.6 intersectMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\]](#), page 1151).

Usage: `intersectMon (I,J)`; I, J ideals.

Return: an ideal, the intersection of I and J .
(it returns -1 if I or J are not monomial ideals)

Assume: I, J are monomial ideals of the basering.

Note: the minimal monomial generating set is returned.

Example:

```
LIB "monomialideal.lib";
ring R = 0, (w,x,y,z,t), lp;
ideal I = w^3*x*y, w*x*y*z*t, x^2*y^2*z^2, x^2*z^4*t^3, y^3*z;
ideal J = w*x, x^2, y*z*t, y^5*t;
intersectMon (I,J);
```

```

↳ _[1]=y3zt
↳ _[2]=wxyz
↳ _[3]=w3xy
↳ _[4]=x2y2z2
↳ _[5]=x2z4t3
↳ _[6]=x2y3z
↳ _[7]=wxy3z

```

D.4.17.7 quotientMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\]](#), page 1151).

Usage: `quotientMon (I,J)`; I,J ideals.

Return: an ideal, the quotient I:J.
 (returns -1 if I or J is not monomial)

Assume: I,J are monomial ideals of the basering.

Note: the minimal monomial generating set is returned.

Example:

```

LIB "monomialideal.lib";
ring R = 0,(w,x,y,z,t),lp;
ideal I = w^3*x*y,w*x*y*z*t,x^2*y^2*z^2,x^2*z^4*t^3,y^3*z;
ideal J = w*x, x^2, y*z*t, y^5*t;
quotientMon (I,J);
↳ _[1]=y2z2t
↳ _[2]=y3z
↳ _[3]=xy2z2
↳ _[4]=x2z4t3
↳ _[5]=wy2zt
↳ _[6]=wxz4t3
↳ _[7]=wxyz

↳ _[9]=w3y2z
↳ _[10]=w3xy

```

D.4.17.8 radicalMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\]](#), page 1151).

Usage: `radicalMon(I)`; I ideal

Return: an ideal, the radical ideal of the ideal I.
 (returns -1 if I is not a monomial ideal)

Assume: I is a monomial ideal of the basering.

Note: the minimal monomial generating set is returned.

Example:

```

LIB "monomialideal.lib";
ring R = 0,(w,x,y,z,t),lp;
ideal I = w^3*x*y,w*x*y*z*t,x^2*y^2*z^2,x^2*z^4*t^3,y^3*z;
radicalMon(I);
↳ _[1]=yz
↳ _[2]=xzt
↳ _[3]=wxy

```

D.4.17.9 isprimeMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\]](#), page 1151).

Usage: `isprimeMon (I);` I ideal
Return: 1, if I is prime; 0, otherwise.
 (returns -1 if I is not a monomial ideal)
Assume: I is a monomial ideal of the basering.

Example:

```
LIB "monomialideal.lib";
ring R = 0,(w,x,y,z,t),lp;
ideal I = w,y,t;
isprimeMon (I);
↪ 1
ideal J = w,y,t,x*z;
isprimeMon (J);
↪ 0
```

D.4.17.10 isprimaryMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\]](#), page 1151).

Usage: `isprimaryMon (I);` I ideal
Return: 1, if I is primary; 0, otherwise.
 (returns -1 if I is not a monomial ideal)
Assume: I is a monomial ideal of the basering.

Example:

```
LIB "monomialideal.lib";
ring R = 0,(w,x,y,z,t),lp;
ideal I = w^4,x^3,z^2,t^5,x*t,w*x^2*z;
isprimaryMon (I);
↪ 1
ideal J = w^4,x^3,z^2,t^5,x*t,w*x^2*z,y^3*t^3;
isprimaryMon (J);
↪ 0
```

D.4.17.11 isirreducibleMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\]](#), page 1151).

Usage: `isirreducibleMon(I);` I ideal
Return: 1, if I is irreducible; 0, otherwise.
 (return -1 if I is not a monomial ideal)
Assume: I is a monomial ideal of the basering.

Example:

```
LIB "monomialideal.lib";
ring R = 0,(w,x,y,z,t),lp;
ideal I = w^4,x^3,z^2,t^5;
isirreducibleMon (I);
```

```

⇒ 1
ideal J = w^4*x,x^3,z^2,t^5;
isirreducibleMon (J);
⇒ 0

```

D.4.17.12 isartinianMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\]](#), page 1151).

Usage: `isartinianMon(I);` I ideal.

Return: 1, if ideal is artinian; 0, otherwise.
(return -1 if ideal I is not a monomial ideal).

Assume: I is a monomial ideal of the basering.

Example:

```

LIB "monomialideal.lib";
ring R = 0,(w,x,y,z,t),lp;
ideal I = w^4,x^3,y^4,z^2,t^6,w^2*x^2*y,w*z*t^4,x^2*y^3,z^2*t^5;
isartinianMon (I);
⇒ 1
ideal J = w^4,x^3,y^4,z^2,w^2*x^2*y,w*z*t^4,x^2*y^3,z^2*t^5;
isartinianMon (J);
⇒ 0

```

D.4.17.13 isgenericMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\]](#), page 1151).

Usage: `isgenericMon(I);` I ideal.

Return: 1, if ideal is generic; 0, otherwise.
(return -1 if ideal I is not a monomial ideal)

Assume: I is a monomial ideal of the basering.

Example:

```

LIB "monomialideal.lib";
ring R = 0,(w,x,y,z,t),lp;
ideal I = w^4,x^3,y^4,z^2,w^2*x^2*y,w*z*t^4,x*y^3,z*t^5;
isgenericMon (I);
⇒ 0
ideal J = w^4,x^3,y^4,z^3,w^2*x^2*y,w*z*t^4,x*y^3,z^2*t^5;
isgenericMon (J);
⇒ 1

```

D.4.17.14 dimMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\]](#), page 1151).

Usage: `dimMon (I);` I ideal

Return: an integer, the dimension of the affine variety defined by the ideal I.
(returns -1 if I is not a monomial ideal)

Assume: I is a monomial ideal of the basering.

Example:

```

LIB "monomialideal.lib";
ring R = 0,(w,x,y,z,t),lp;
ideal I = w^3*x*y,w*x*y*z*t,x^2*y^2*z^2,x^2*z^4*t^3,y^3*z;
dimMon (I);
⇒ 3
ideal J = w^4,x^3,y^4,z^2,t^6,w^2*x^2*y,w*z*t^4,x^2*y^3,z*t^5;
dimMon (J);
⇒ 0

```

D.4.17.15 irreddecMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\]](#), page 1151).

Usage: `irreddecMon (I[,alg]);` I ideal, alg string.

Return: list, the irreducible components of the monomial ideal I. (returns -1 if I is not a monomial ideal).

Assume: I is a monomial ideal of the basering $k[x(1)..x(n)]$.

Note: This procedure returns the irreducible decomposition of I. One may call the procedure with different algorithms using the optional argument 'alg':

- the direct method following Vasconcelos' book (`alg=vas`) - via the Alexander dual and using double dual (`alg=add`), - via the Alexander dual and quotients following E. Miller (`alg=ad`),
- the formula of irreducible components (`alg=for`),
- via the Scarf complex following Milowski (`alg=mil`),
- using the label algorithm of Roune (`alg=lr`),
- using the algorithm of Gao-Zhu (`alg=gz`).
- using the slice algorithm of Roune (`alg=sr`).

Example:

```

LIB "monomialideal.lib";
ring R = 0,(w,x,y,z),Dp;
ideal I = w^3*x*y,w*x*y*z,x^2*y^2*z^2,x^2*z^4,y^3*z;
// Vasconcelos

```

D.4.17.16 primdecMon

Procedure from library `monomialideal.lib` (see [Section D.4.17 \[monomialideal.lib\]](#), page 1151).

Usage: `primdecMon (I[,alg]);` I ideal, alg string

Return: list, the components in a minimal primary decomposition of I. (returns -1 if I is not a monomial ideal).

Assume: I is a monomial ideal of the basering $k[x(1)..x(n)]$.

Note: This procedure returns a minimal primary decomposition of I . One may call the procedure with different algorithms using the optional argument 'alg':

- the direct method for a primary decomposition following Vasconcelos' book (alg=vp),
- from the irreducible decomposition obtained via the direct method following Vasconcelos' book (alg=vi),
- from the irreducible decomposition obtained via the Alexander dual and using double dual (alg=add),
- from the irreducible decomposition obtained via the Alexander dual and quotients following E. Miller (alg=ad),
- from the irreducible decomposition obtained via (alg=for),
- from the irreducible decomposition obtained via the Scarf complex following Milowski (alg=mil),
- from the irreducible decomposition obtained using the label algorithm of Roune (alg=lr),

D.4.18 mprimdec_lib

Library: mprimdec.lib

Purpose: procedures for primary decomposition of modules

Authors: Alexander Dreyer, dreyer@mathematik.uni-kl.de; adreyer@web.de

Overview: Algorithms for primary decomposition for modules based on the algorithms of Gianni, Trager and Zacharias and Shimoyama and Yokoyama (generalization of the latter suggested by Hans-Gert Graebe, Leipzig) using elements of primdec.lib

Remark: These procedures are implemented to be used in characteristic 0. They also work in positive characteristic $\gg 0$. In small characteristic and for algebraic extensions, the procedures via Gianni, Trager, Zacharias may not terminate.

Procedures:

D.4.18.1 separator

Procedure from library `mprimdec.lib` (see [Section D.4.18 \[mprimdec.lib\]](#), page 1162).

Usage: separator(l); list l of prime ideals

Return: list sepList;
a list of separators of the prime ideals in l,
i.e. polynomials p_{ij} , s.th. p_{ij} is in $l[j]$,
for all $l[j]$ not contained in $l[i]$
but p_{ij} is not in $l[i]$

Example:

```

LIB "mprimdec.lib";
ring r=0,(x,y,z),dp;
ideal i=(x2y,xz2,y2z,z3);

```

```

list l=minAssGTZ(i);
list sepL=separator(l);
sepL;
↳ [1]:
↳      x
↳ [2]:
↳      y

```

D.4.18.2 PrimdecA

Procedure from library `mprimdec.lib` (see [Section D.4.18 \[mprimdec.lib\]](#), page 1162).

Usage: PrimdecA (N[, i]); module N, int i

Return: list l
 a (not necessarily minimal) primary decomposition of N computed by a generalized version of the algorithm of Shimoyama/Yokoyama,
 if i!=0 is given, the factorizing Groebner is used to compute the isolated primes

Example:

```

LIB "mprimdec.lib";
ring r=0,(x,y,z),dp;
module N=x*gen(1)+ y*gen(2),
x*gen(1)-x2*gen(2);
list l=PrimdecA(N);
l;
↳ [1]:
↳      [1]:
↳          _[1]=x*gen(1)+y*gen(2)
↳          _[2]=x*gen(2)-gen(1)
↳      [2]:
↳          _[1]=x2+y
↳ [2]:
↳      [1]:
↳          _[1]=gen(2)
↳          _[2]=x*gen(1)
↳      [2]:
↳          _[1]=x
↳ [3]:
↳      [1]:
↳          _[1]=y*gen(1)
↳          _[2]=y*gen(2)
↳          _[3]=x*gen(1)
↳          _[4]=x*gen(2)
↳      [2]:
↳          _[1]=y
↳          _[2]=x

```

D.4.18.3 PrimdecB

Procedure from library `mprimdec.lib` (see [Section D.4.18 \[mprimdec.lib\]](#), page 1162).

Usage: PrimdecB (N, p); pseudo-primary module N, isolated prime ideal p

Return: list l
 a (not necessarily minimal) primary decomposition of N

Example:

```

LIB "mprimdec.lib";
ring r=0,(x,y,z),dp;
module N=y*gen(1),y2*gen(2),yz*gen(2),yx*gen(2);
ideal p=y;
list l=PrimdecB(N,p);
l;
⇒ [1]:
⇒ [1]:
⇒ _[1]=y*gen(1)
⇒ _[2]=y*gen(2)
⇒ [2]:
⇒ _[1]=y
⇒ [2]:
⇒ [1]:
⇒ _[1]=y*gen(1)
⇒ _[2]=y*gen(2)
⇒ _[3]=x*gen(1)
⇒ _[4]=x*gen(2)
⇒ [2]:
⇒ _[1]=y
⇒ _[2]=x
⇒ [3]:
⇒ [1]:
⇒ _[1]=z*gen(1)
⇒ _[2]=z*gen(2)
⇒ _[3]=y*gen(1)
⇒ _[4]=x*gen(1)
⇒ _[5]=x*gen(2)
⇒ _[6]=y2*gen(2)
⇒ [2]:
⇒ _[1]=z
⇒ _[2]=y
⇒ _[3]=x

```

D.4.18.4 modDec

Procedure from library `mprimdec.lib` (see [Section D.4.18 \[mprimdec.lib\]](#), page 1162).

Usage: modDec (N[, i]); module N, int i

Return: list l
a minimal primary decomposition of N
computed by an generalized version of the algorithm of Shimoyama/Yokoyama,
if i=1 is given, the factorizing Groebner basis algorithm is used internally.

Example:

```

LIB "mprimdec.lib";
ring r=0,(x,y,z),dp;
module N=x*gen(1)+ y*gen(2),
x*gen(1)-x2*gen(2);
list l=modDec(N);
l;
⇒ [1]:

```

```

⇒      [1]:
⇒      _[1]=x*gen(1)+y*gen(2)
⇒      _[2]=x*gen(2)-gen(1)
⇒      [2]:
⇒      _[1]=x2+y
⇒ [2]:
⇒      [1]:
⇒      _[1]=gen(2)
⇒      _[2]=x*gen(1)
⇒      [2]:
⇒      _[1]=x

```

D.4.18.5 zeroMod

Procedure from library `mprimdec.lib` (see [Section D.4.18 \[mprimdec.lib\]](#), page 1162).

Usage: `zeroMod (N[, check]);` zero-dimensional module `N[, module check]`

Return: `list l`
the minimal primary decomposition of a zero-dimensional module `N`, computed by a generalized version of the algorithm of Gianni, Trager and Zacharias

Note: if the parameter `check` is given, only components not containing `check` are computed

Example:

```

LIB "mprimdec.lib";
ring r=0,z,dp;
module N=z*gen(1),(z-1)*gen(2),(z+1)*gen(3);
list l=zeroMod(N);
⇒ 2
l;
⇒ [1]:
⇒      [1]:
⇒      _[1]=gen(2)
⇒      _[2]=gen(3)
⇒      _[3]=z*gen(1)
⇒      [2]:
⇒      _[1]=z
⇒ [2]:
⇒      [1]:
⇒      _[1]=gen(1)
⇒      _[2]=gen(3)
⇒      _[3]=z*gen(2)-gen(2)
⇒      [2]:
⇒      _[1]=z-1
⇒ [3]:
⇒      [1]:
⇒      _[1]=gen(1)
⇒      _[2]=gen(2)
⇒      _[3]=z*gen(3)+gen(3)
⇒      [2]:
⇒      _[1]=z+1

```

D.4.18.6 GTZmod

Procedure from library `mprimdec.lib` (see [Section D.4.18 \[mprimdec.lib\]](#), page 1162).

Usage: GTZmod (N[, check]); module N[, module check]

Return: list l
the minimal primary decomposition of the module N,
computed by a generalized version of the algorithm of Gianni, Trager and Zacharias

Note: if the parameter check is given, only components not containing check are computed

Example:

```
LIB "mprimdec.lib";
ring r=0,(x,y,z),dp;
module N=x*gen(1)+ y*gen(2),
x*gen(1)-x2*gen(2);
list l=GTZmod(N);
⇒ 2
l;
⇒ [1]:
⇒ [1]:
⇒ _[1]=gen(2)
⇒ _[2]=x*gen(1)
⇒ [2]:
⇒ _[1]=x
⇒ [2]:
⇒ [1]:
⇒ _[1]=x*gen(1)+y*gen(2)
⇒ _[2]=x*gen(2)-gen(1)
⇒ [2]:
⇒ _[1]=x2+y
```

D.4.18.7 declvar

Procedure from library `mprimdec.lib` (see [Section D.4.18 \[mprimdec.lib\]](#), page 1162).

Usage: declvar (N); zero-dimensional module N[, module check]

Return: list l
the minimal primary decomposition of a submodule N of R^s if $\text{nvars}(R)=1$

Note: if the parameter check is given, only components not containing check are computed

Example:

```
LIB "mprimdec.lib";
ring r=0,z,dp;
module N=z*gen(1),(z-1)*gen(2),(z+1)*gen(3);
list l=declvar(N);
l;
⇒ [1]:
⇒ [1]:
⇒ _[1]=gen(2)
⇒ _[2]=gen(3)
⇒ _[3]=z*gen(1)
⇒ [2]:
⇒ _[1]=z
⇒ [2]:
⇒ [1]:
⇒ _[1]=gen(1)
```

```

↳      _[2]=gen(3)
↳      _[3]=z*gen(2)-gen(2)
↳      [2]:
↳      _[1]=z-1
↳      [3]:
↳      [1]:
↳      _[1]=gen(1)
↳      _[2]=gen(2)
↳      _[3]=z*gen(3)+gen(3)
↳      [2]:
↳      _[1]=z+1

```

D.4.18.8 annil

Procedure from library `mprimdec.lib` (see [Section D.4.18 \[mprimdec.lib\]](#), page 1162).

Usage: `annil(N); modul N`

Return: `ideal ann=std(quotient(N,freemodule(nrows(N))));`
the annihilator of M/N in the basering

Note: `ann` is a std basis in the basering

Example:

```

LIB "mprimdec.lib";
ring r=0,(x,y,z),dp;
module N=x*gen(1), y*gen(2);
ideal ann=annil(N);
ann;
↳ ann[1]=xy

```

D.4.18.9 splitting

Procedure from library `mprimdec.lib` (see [Section D.4.18 \[mprimdec.lib\]](#), page 1162).

Usage: `splitting(N[,check[, ann]]); modul N, module check, ideal ann`

Return: `(l, check)` list `l`, module `check`
the elements of `l` consists of quadruples, where
`[1]` is of type module, `[2]`, `[3]` and `[4]` are of type ideal, s.th. the intersection of the
modules is equal to the zero-dimensional module N , furthermore `l[j][3]=annil(l[j][1])`
and `l[j][4]` contains internal ideal data;
if `l[j][2] != 0` then the module `l[j][1]` is primary
with associated prime `l[j][2]`, and `check=intersect(check, l[j][1])` is computed

Note: if the parameter `check` is given, only components not containing `check` are computed;
if `ann` is given, `ann` is used instead of `annil(N)`

Example:

```

LIB "mprimdec.lib";
ring r=0,z,lp;
module N=z*gen(1), (z+1)*gen(2);
N=std(N);
list l; module check;
(l, check)=splitting(N);
l;

```

```

⇒ [1]:
⇒ [1]:
⇒ [1]=gen(2)
⇒ [2]=z*gen(1)
⇒ [2]:
⇒ [1]=z
⇒ [3]:
⇒ [1]=z
⇒ [4]:
⇒ [1]=z
⇒ [2]:
⇒ [1]:
⇒ [1]=gen(1)
⇒ [2]=z*gen(2)+gen(2)
⇒ [2]:
⇒ [1]=z+1
⇒ [3]:
⇒ [1]=z+1
⇒ [4]:
⇒ [1]=z+1
check;
⇒ check[1]=z*gen(2)+gen(2)
⇒ check[2]=z*gen(1)

```

D.4.18.10 primTest

Procedure from library `mprimdec.lib` (see [Section D.4.18 \[mprimdec.lib\]](#), page 1162).

Usage: `primTest(i[, p]);` a zero-dimensional ideal `i`, irreducible poly `p` in `i`

Return: if `i` is neither prime nor homogeneous then `ideal(0)` is returned, otherwise `radical(i)`

Example:

```

LIB "mprimdec.lib";
ring r=0,(x,y,z),lp;
ideal i=x+1,y-1,z;
i=std(i);
ideal primId=primTest(i,z);
primId;
⇒ primId[1]=z
⇒ primId[2]=y-1
⇒ primId[3]=x+1
i=x,z2,yz,y2;
i=std(i);
primId=primTest(i);
primId;
⇒ primId[1]=x
⇒ primId[2]=y
⇒ primId[3]=z

```

D.4.18.11 preComp

Procedure from library `mprimdec.lib` (see [Section D.4.18 \[mprimdec.lib\]](#), page 1162).

Usage: `preComp(N,check[, ann]);` modul `N`, module `check`, ideal `ann`

- Return:** (l, check) list l, module check
the elements of l consists of a triple with
[1] of type module [2] and [3] of type ideal
s.th. the intersection of the modules is equal to the zero-dimensional module N, furthermore $l[j][3] = \text{annil}(l[j][1])$ if $l[j][2] \neq 0$ then the module $l[j][1]$ is primary with associated prime $l[j][2]$,
and $\text{check} = \text{intersect}(\text{check}, l[j][1])$ is computed
- Note:** only components not containing check are computed;
if ann is given, ann is used instead of $\text{annil}(N)$

Example:

```
LIB "mprimdec.lib";
ring r=0,z,lp;
module N=z*gen(1), (z+1)*gen(2);
N=std(N);
list l; module check;
(l, check)=preComp(N, freemodule(2));
l;
⇒ [1]:
⇒ [1]:
⇒ _[1]=z*gen(1)
⇒ _[2]=gen(2)
⇒ [2]:
⇒ _[1]=z
⇒ [3]:
⇒ _[1]=z
⇒ [2]:
⇒ [1]:
⇒ _[1]=gen(1)
⇒ _[2]=z*gen(2)+gen(2)
⇒ [2]:
⇒ _[1]=z+1
⇒ [3]:
⇒ _[1]=z+1
check;
⇒ check[1]=z*gen(1)
⇒ check[2]=z*gen(2)+gen(2)
```

D.4.18.12 indSet

Procedure from library `mprimdec.lib` (see [Section D.4.18 \[mprimdec.lib\]](#), page 1162).

- Usage:** `indSet(i); i ideal`
- Return:** list with two entries
both are lists of new varstrings with the dependent variables, the independent set, the ordstring with the corresp. block ordering, and the integer where the independent set starts in the varstring
- Note:** the first entry gives the strings for all maximal independent sets the second gives the strings for the independent sets, which cannot be enhanced

Example:

```

LIB "mprimdec.lib";
ring s1=(0,x,y),(a,b,c,d,e,f,g),lp;
ideal i=ea-fbg,fa+be,ec-fdg,fc+de;
i=std(i);
list l=indSet(i);
l;
⇒ [1]:
⇒   [1]:
⇒     [1]:
⇒       e,f
⇒     [2]:
⇒       a,b,c,d,g
⇒     [3]:
⇒       (C,dp(2),dp)
⇒     [4]:
⇒       5
⇒ [2]:
⇒   [1]:
⇒     [1]:
⇒       a,b,c,d
⇒     [2]:
⇒       e,f,g
⇒     [3]:
⇒       (C,dp(4),dp)
⇒     [4]:
⇒       3
⇒   [2]:
⇒     [1]:
⇒       a,c,e
⇒     [2]:
⇒       b,d,f,g
⇒     [3]:
⇒       (C,dp(3),dp)
⇒     [4]:
⇒       4

```

D.4.18.13 GTZopt

Procedure from library `mprimdec.lib` (see [Section D.4.18 \[mprimdec.lib\]](#), page 1162).

Usage: GTZopt (N[, check]); module N[, module check]

Return: list l
the minimal primary decomposition of the module N,
computed by a generalized and optimized version of
the algorithm of Gianni, Trager and Zacharias

Note: if the parameter check is given, only components
not containing check are computed

Example:

```

LIB "mprimdec.lib";
ring r=0,(x,y,z),dp;
module N=x*gen(1)+ y*gen(2),
x*gen(1)-x2*gen(2);

```

```

list l=GTZopt(N);
l;
⇒ [1]:
⇒   [1]:
⇒     _[1]=gen(2)
⇒     _[2]=x*gen(1)
⇒   [2]:
⇒     _[1]=x
⇒ [2]:
⇒   [1]:
⇒     _[1]=x*gen(1)+y*gen(2)
⇒     _[2]=x*gen(2)-gen(1)
⇒   [2]:
⇒     _[1]=x2+y

```

D.4.18.14 zeroOpt

Procedure from library `mprimdec.lib` (see [Section D.4.18 \[mprimdec.lib\]](#), page 1162).

Usage: `zeroOpt (N[, check]);` zero-dimensional module N[, module check]

Return: list l
 the minimal primary decomposition of a zero-dimensional module N, computed by a
 generalized and optimized version of the algorithm of Gianni, Trager and Zacharias

Note: if the parameter check is given, only components
 not containing check are computed

Example:

```

LIB "mprimdec.lib";
ring r=0,z,dp;
module N=z*gen(1),(z-1)*gen(2),(z+1)*gen(3);
list l=zeroOpt(N);
l;
⇒ [1]:
⇒   [1]:
⇒     _[1]=z*gen(1)
⇒     _[2]=gen(2)
⇒     _[3]=gen(3)
⇒   [2]:
⇒     _[1]=z
⇒ [2]:
⇒   [1]:
⇒     _[1]=gen(1)
⇒     _[2]=z*gen(2)-gen(2)
⇒     _[3]=gen(3)
⇒   [2]:
⇒     _[1]=z-1
⇒ [3]:
⇒   [1]:
⇒     _[1]=gen(1)
⇒     _[2]=gen(2)
⇒     _[3]=z*gen(3)+gen(3)
⇒   [2]:
⇒     _[1]=z+1

```

D.4.19 mregular.lib

Library: mregular.lib

Purpose: Castelnuovo-Mumford regularity of homogeneous ideals

Authors: I.Bermejo, ibermejo@ull.es
 Ph.Gimenez, pgimenez@agt.uva.es
 G.-M.Greuel, greuel@mathematik.uni-kl.de

Overview: A library for computing the Castelnuovo-Mumford regularity of a homogeneous ideal that DOES NOT require the computation of a minimal graded free resolution of the ideal.

It also determines $\text{depth}(\text{basing}/\text{ideal})$ and $\text{satiety}(\text{ideal})$. The procedures are based on 3 papers by Isabel Bermejo and Philippe Gimenez: 'On Castelnuovo-Mumford regularity of projective curves' Proc.Amer.Math.Soc. 128(5) (2000), 'Computing the Castelnuovo-Mumford regularity of some subschemes of P^n using quotients of monomial ideals', Proceedings of MEGA-2000, J. Pure Appl. Algebra 164 (2001), and 'Saturation and Castelnuovo-Mumford regularity', Preprint (2004).

Procedures:

D.4.19.1 regIdeal

Procedure from library mregular.lib (see [Section D.4.19 \[mregular.lib\]](#), page 1172).

Usage: regIdeal (i[e]); i ideal, e integer

Return: an integer, the Castelnuovo-Mumford regularity of i.
 (returns -1 if i is not homogeneous)

Assume: i is a homogeneous ideal of the basering $S=K[x(0)..x(n)]$. e=0: (default)
 If K is an infinite field, makes random changes of coordinates. If K is a finite field, works over a transcendental extension. e=1: Makes random changes of coordinates even when K is finite. It works if it terminates, but may result in an infinite loop. After 30 loops, a warning message is displayed and -1 is returned.

Note: If $\text{printlevel} > 0$ (default = 0), additional info is displayed: $\dim(S/i)$, $\text{depth}(S/i)$ and $\text{end}(H^{\text{depth}(S/i)}(S/i))$ are computed, and an upper bound for the a-invariant of S/i is given. The algorithm also determines whether the regularity is attained or not at the last step of a minimal graded free resolution of i, and if the answer is positive, the regularity of the Hilbert function of S/i is given.

Example:

```
LIB "mregular.lib";
ring r=0,(x,y,z,t,w),dp;
ideal i=y2t,x2y-x2z+yt2,x2y2,xyztw,x3z2,y5+xz3w-x2zw2,x7-yt2w4;
regIdeal(i);
  ↳ 10
regIdeal(lead(std(i)));
  ↳ 13
// Additional information is displayed if you change printlevel (=1);
```

D.4.19.2 depthIdeal

Procedure from library `mregular.lib` (see [Section D.4.19 \[mregular.lib\]](#), page 1172).

Usage: `depthIdeal (i[,e]);` i ideal, e integer

Return: an integer, the depth of S/i where $S=K[x(0)..x(n)]$ is the basering. (returns -1 if i is not homogeneous or if $i=(1)$)

Assume: i is a proper homogeneous ideal.

$e=0$: (default)

If K is an infinite field, makes random changes of coordinates. If K is a finite field, works over a transcendental extension. $e=1$: Makes random changes of coordinates even when K is finite. It works if it terminates, but may result in an infinite loop. After 30 loops, a warning message is displayed and -1 is returned.

Note: If `printlevel > 0` (default = 0), $\dim(S/i)$ is also displayed.

Example:

```
LIB "mregular.lib";
ring r=0,(x,y,z,t,w),dp;
ideal i=y2t,x2y-x2z+yt2,x2y2,xyztw,x3z2,y5+xz3w-x2zw2,x7-yt2w4;
depthIdeal(i);
  ↪ 1
depthIdeal(lead(std(i)));
  ↪ 0
// Additional information is displayed if you change printlevel (=1);
```

D.4.19.3 satiety

Procedure from library `mregular.lib` (see [Section D.4.19 \[mregular.lib\]](#), page 1172).

Usage: `satiety (i[,e]);` i ideal, e integer

Return: an integer, the satiety of i .
(returns -1 if i is not homogeneous)

Assume: i is a homogeneous ideal of the basering $S=K[x(0)..x(n)]$. $e=0$: (default)

The satiety is computed determining the fresh elements in the socle of i . It works over arbitrary fields.

$e=1$: Makes random changes of coordinates to find a monomial ideal with same satiety. It works over infinite fields only. If K is finite, it works if it terminates, but may result in an infinite loop. After 30 loops, a warning message is displayed and -1 is returned.

Theory: The satiety, or saturation index, of a homogeneous ideal i is the least integer s such that, for all $d \geq s$, the degree d part of the ideals i and $\text{isat}=\text{sat}(i, \text{maxideal}(1))$ coincide.

Note: If `printlevel > 0` (default = 0), $\dim(S/i)$ is also displayed.

Example:

```
LIB "mregular.lib";
ring r=0,(x,y,z,t,w),dp;
ideal i=y2t,x2y-x2z+yt2,x2y2,xyztw,x3z2,y5+xz3w-x2zw2,x7-yt2w4;
satiety(i);
  ↪ 0
ideal I=lead(std(i));
satiety(I); // First method: direct computation
```

```

    ↪ 12
    satiety(I,1); // Second method: doing changes of coordinates
    ↪ 12
    // Additional information is displayed if you change printlevel (=1);

```

D.4.19.4 regMonCurve

Procedure from library `mregular.lib` (see [Section D.4.19 \[mregular.lib\]](#), page 1172).

- Usage:** `regMonCurve (a0,...,an)` ; a_i integers with $a_0=0 < a_1 < \dots < a_n=:d$
- Return:** an integer, the Castelnuovo-Mumford regularity of the projective monomial curve C in $P_n(K)$ parametrically defined by $x(0) = t^d$, $x(1) = s^{a_1}t^{(d-a_1)}$, ..., $x(n) = s^d$ where K is the field of complex numbers.
(returns -1 if $a_0=0 < a_1 < \dots < a_n$ is not satisfied)
- Assume:** $a_0=0 < a_1 < \dots < a_n$ are integers.
- Notes:**
1. The defining ideal of the curve C , I in $S=K[x(0),\dots,x(n)]$, is determined by elimination.
 2. The procedure `regIdeal` has been improved in this case since one knows beforehand that the monomial ideal $J=\text{lead}(\text{std}(I))$ is of nested type if the monomial ordering is `dp`, and that $\text{reg}(C)=\text{reg}(J)$ (see preprint 'Saturation and Castelnuovo-Mumford regularity' by Bermejo-Gimenez, 2004).
 3. If `printlevel > 0` (default = 0) additional info is displayed: - It says whether C is arithmetically Cohen-Macaulay or not. - If C is not arith. Cohen-Macaulay, $\text{end}(H^1(S/I))$ is computed and an upper bound for the a -invariant of S/I is given. - It also determines one step of the minimal graded free resolution (m.g.f.r.) of I where the regularity is attained and gives the value of the regularity of the Hilbert function of S/I when $\text{reg}(I)$ is attained at the last step of a m.g.f.r.

Example:

```

LIB "mregular.lib";
// The 1st example is the twisted cubic:
regMonCurve(0,1,2,3);
↪ 2
// The 2nd. example is the non arithm. Cohen-Macaulay monomial curve in P4
// parametrized by: x(0)-s6,x(1)-s5t,x(2)-s3t3,x(3)-st5,x(4)-t6:
regMonCurve(0,1,3,5,6);
↪ 3
// Additional information is displayed if you change printlevel (=1);

```

D.4.19.5 NoetherPosition

Procedure from library `mregular.lib` (see [Section D.4.19 \[mregular.lib\]](#), page 1172).

- Usage:** `NoetherPosition (i)`; i ideal
- Return:** ideal such that, for the homogeneous linear transformation $\text{map } \phi=S, \text{NoetherPosition}(i)$; one has that $K[x(n-d+1),\dots,x(n)]$ is a Noether normalization of $S/\phi(i)$ where $S=K[x(0),\dots,x(n)]$ is the basering and $d=\dim(S/i)$. (returns -1 if $i = (0)$ or (1)).
- Assume:** The field K is infinite and i is a nonzero proper ideal.

- Note:**
1. It works also if K is a finite field if it terminates, but may result in an infinite loop. If the procedure enters more than 30 loops, -1 is returned and a warning message is displayed.
 2. If `printlevel > 0` (default = 0), additional info is displayed: $\dim(S/i)$ and $K[x(n-d+1), \dots, x(n)]$ are given.

Example:

```
LIB "mregular.lib";
ring r=0,(x,y,z,t,u),dp;
ideal i1=y,z,t,u; ideal i2=x,z,t,u; ideal i3=x,y,t,u; ideal i4=x,y,z,u;
ideal i5=x,y,z,t; ideal i=intersect(i1,i2,i3,i4,i5);
map phi=r,NoetherPosition(i);
phi;
  ↳ phi[1]=x
  ↳ phi[2]=y
  ↳ phi[3]=z
  ↳ phi[4]=t
  ↳ phi[5]=53x+27y-75z+45t+u
ring r5=5,(x,y,z,t,u),dp;
ideal i=imap(r,i);
map phi=r5,NoetherPosition(i);
phi;
  ↳ phi[1]=x
  ↳ phi[2]=y
  ↳ phi[3]=z
  ↳ phi[4]=t
  ↳ phi[5]=x-y+z-t+u
// Additional information is displayed if you change printlevel (=1);
```

D.4.19.6 is_NP

Procedure from library `mregular.lib` (see [Section D.4.19 \[mregular.lib\]](#), page 1172).

Usage: `is_NP (i); i ideal`

Return: 1 if $K[x(n-d+1), \dots, x(n)]$ is a Noether normalization of S/i where $S=K[x(0), \dots, x(n)]$ is the basering, and $d=\dim(S/i)$, 0 otherwise.
(returns -1 if $i=(0)$ or $i=(1)$).

Assume: i is a nonzero proper homogeneous ideal.

- Note:**
1. If i is not homogeneous and `is_NP(i)=1` then $K[x(n-d+1), \dots, x(n)]$ is a Noether normalization of S/i . The converse may be wrong if the ideal is not homogeneous.
 2. `is_NP` is used in the procedures `regIdeal`, `depthIdeal`, `satiety`, and `NoetherPosition`.

Example:

```
LIB "mregular.lib";
ring r=0,(x,y,z,t,u),dp;
ideal i1=y,z,t,u; ideal i2=x,z,t,u; ideal i3=x,y,t,u; ideal i4=x,y,z,u;
ideal i5=x,y,z,t; ideal i=intersect(i1,i2,i3,i4,i5);
is_NP(i);
  ↳ 0
ideal ch=x,y,z,t,x+y+z+t+u;
map phi=ch;
is_NP(phi(i));
  ↳ 1
```

D.4.19.7 is_nested

Procedure from library `mregular.lib` (see [Section D.4.19 \[mregular.lib\]](#), page 1172).

Usage: `is_nested (i);` i monomial ideal

Return: 1 if i is of nested type, 0 otherwise.
(returns -1 if $i=(0)$ or $i=(1)$).

Assume: i is a nonzero proper monomial ideal.

Notes: 1. The ideal must be monomial, otherwise the result has no meaning (so check this before using this procedure).
2. `is_nested` is used in procedures `depthIdeal`, `regIdeal` and `satiety`.
3. When i is a monomial ideal of nested type of $S=K[x(0)..x(n)]$, the a -invariant of S/i coincides with the upper bound obtained using the procedure `regIdeal` with `printlevel > 0`.

Theory: A monomial ideal is of nested type if its associated primes are all of the form $(x(0), \dots, x(i))$ for some $i \leq n$.
(see definition and effective criterion to check this property in the preprint 'Saturation and Castelnuovo-Mumford regularity' by Bermejo-Gimenez, 2004).

Example:

```
LIB "mregular.lib";
ring s=0,(x,y,z,t),dp;
ideal i1=x2,y3; ideal i2=x3,y2,z2; ideal i3=x3,y2,t2;
ideal i=intersect(i1,i2,i3);
is_nested(i);
  ↦ 0
ideal ch=x,y,z,z+t;
map phi=ch;
ideal I=lead(std(phi(i)));
is_nested(I);
  ↦ 1
```

D.4.20 nfmodstd.lib

Library: `nfmodstd.lib`

Purpose: Groebner bases of ideals in polynomial rings over algebraic number fields

Authors: D.K. Boku boku@mathematik.uni-kl.de
W. Decker decker@mathematik.uni-kl.de
C. Fieker fieker@mathematik.uni-kl.de

Overview: A library for computing the Groebner basis of an ideal in the polynomial ring over an algebraic number field $Q(t)$ using the modular methods, where t is algebraic over the field of rational numbers Q . For the case $Q(t) = Q$, the procedure is inspired by Arnold [1]. This idea is then extended to the case t not in Q using factorization as follows:
Let f be the minimal polynomial of t .
For I, I' ideals in $Q(t)[X]$, $Q[X,t]/\langle f \rangle$ respectively, we map I to I' via the map sending t to $t + \langle f \rangle$. We first choose a prime p such that f has at least two factors in characteristic p and add each factor f_i to I' to obtain the ideal $J'_i = I' + \langle f_i \rangle$. We then compute a standard basis G'_i of J'_i for each i and combine the G'_i to G_p (a standard basis of I'_p) using chinese remaindering for polynomials. The procedure is repeated for

many primes p , where we compute the G_p in parallel until the number of primes is sufficiently large to recover the correct standard basis G' of I' . Finally, by mapping G' back to $Q(t)[X]$, a standard basis G of I is obtained.

The procedure also works if the input is a module. For this, we consider the rings $A = Q(t)[X]$ and $A' = (Q[t]/\langle f \rangle)[X]$. For submodules I, I' in A^m, A'^m , respectively, we map I to I' via the map sending t to $t + \langle f \rangle$. As above, we first choose a prime p such that f has at least two factors in characteristic p . For each factor $f_{i,p}$ of $f_p := (f \bmod p)$, we set $I'_{i,p} := (I'_p \bmod f_{i,p})$. We then compute a standard basis G'_i of $I'_{i,p}$ over $F_p[t]/\langle f_{i,p} \rangle$ for each i and combine the G'_i to G_p (a standard basis of I'_p) using chinese remaindering for polynomials. The procedure is repeated for many primes p as described above and we finally obtain a standard basis of I .

References:

- [1] E. A. Arnold: Modular algorithms for computing Groebner bases. J. Symb. Comp. 35, 403-419 (2003).

Procedures:

D.4.20.1 chinrempoly

Procedure from library `nfmodstd.lib` (see [Section D.4.20 \[nfmodstd.lib\]](#), page 1176).

Usage: `chinrempoly(l, m);` l list, m list

Return: a polynomial (resp. ideal/module) which is congruent to $l[i]$ modulo $m[i]$ for all i

Note: The procedure applies chinese remaindering to the first argument w.r.t. the moduli given in the second. The elements in the first list must be of the same type which can be polynomial, ideal, or module. The moduli must be of type polynomial. The elements in the second list must be distinct and co-prime.

Example:

```
LIB "nfmodstd.lib";

D.4.20.2 nfmodStd

Procedure from library `nfmodstd.lib` (see [Section D.4.20 \[nfmodstd.lib\]](#), [page 1176](#)).

Usage: `nfmodStd(I, #)`; I ideal or module, # optional parameters

Return: standard basis of I over algebraic number field

Note: The procedure passes to [Section D.4.16.1 \[modStd\]](#), [page 1148](#) if the ground field has no parameter. In this case, the optional parameters # (if given) are directly passed to [Section D.4.16.1 \[modStd\]](#), [page 1148](#).

Example:

```

LIB "nfmodstd.lib";
ring r1 = (0,a),(x,y),dp;
minpoly = a2+1;
ideal k = (a/2+1)*x2+2/3y, 3*x-a*y+ a/7+2;
ideal I = nfmodStd(k);
I;
⇨ I[1]=x+(-1/3a)*y+(1/21a+2/3)
⇨ I[2]=y2+(32/5a-178/35)*y+(-4/7a-195/49)
ring rm = (0,a),(x,y),(c,dp);
minpoly = a3+2a+7;

D.4.21 nfmodsyz_lib

Library: nfmodsyz.lib

Purpose: Syzygy modules of submodules of free modules over algebraic number fields

Authors: D.K. Boku boku@mathematik.uni-kl.de
W. Decker decker@mathematik.uni-kl.de
C. Fieker fieker@mathematik.uni-kl.de

Overview: A library for computing the syzygy module of a given submodule I in a polynomial ring over an algebraic number field $\mathbb{Q}(t)$, where t is an algebraic number, using modular methods. For the case $\mathbb{Q}(t)=\mathbb{Q}$, that is, where t is an element of \mathbb{Q} , we compute, following [1], the syzygy module of I as follows: For a submodule I of A^m with $A = \mathbb{Q}[X]$, we first choose a sufficiently large set of primes P and compute the reduced Groebner basis of the syzygy module of I_p , for each p in P , in parallel. We then use the Chinese remainder algorithm and rational reconstruction to obtain the syzygy module of I over \mathbb{Q} . For the case where t is not in \mathbb{Q} , we compute, following [2], the syzygy module of I as follows:

Let f be the minimal polynomial of t . For a submodule I in A^m with $A = \mathbb{Q}(t)[X]$, we map I to a submodule I' in A^m with $A = (\mathbb{Q}[t]/\langle f \rangle)[X]$ via the map sending t to $t + \langle f \rangle$. We first choose a prime p such that f has at least two factors in characteristic

p . For each factor $f_{\{i,p\}}$ of $f_p := (f \bmod p)$, we set $I'_{\{i,p\}} := (I'_p \bmod f_{\{i,p\}})$. We then compute the reduced Groebner bases G'_i of the syzygy modules of $I'_{\{i,p\}}$ over $F_p[t]/\langle f_{\{i,p\}} \rangle$ and combine the G'_i to G_p (the syzygy module of I'_p) using chinese remaindering for polynomials. As described in [2], the procedure is repeated for many primes p , where we compute the G_p in parallel until the number of primes is sufficiently large to recover the correct generating set for the syzygy module G' of I' which is, considered over $Q(t)$, also a generating set for the syzygy module of I .

Procedures:

D.4.21.1 nfmodSyz

Procedure from library `nfmodsyz.lib` (see [Section D.4.21 \[nfmodsyz.lib\]](#), page 1179).

Usage: `nfmodSyz(I)`; I ideal or module

Return: syzygy module of I over an algebraic number field

Example:

```
LIB "nfmodsyz.lib";
ring r1 =(0,a),(x,y),(c,dp);
minpoly = (a^3+2a+7);
module M1 = [(a/2+1)*y, 3*x-a*y],

D.4.22 noether_lib

Library: noether.lib

Purpose: Noether normalization of an ideal (not necessary homogeneous)

Authors: A. Hashemi, Amir.Hashemi@lip6.fr

Overview: A library for computing the Noether normalization of an ideal that DOES NOT require the computation of the dimension of the ideal. It checks whether an ideal is in Noether position. A modular version of these algorithms is also provided.

The procedures are based on a paper of Amir Hashemi 'Efficient Algorithms for Computing Noether Normalization' (presented in ASCM 2007)

This library computes also Castelnuovo-Mumford regularity and satiety of an ideal. A modular version of these algorithms is also provided. The procedures are based on a paper of Amir Hashemi 'Computation of Castelnuovo-Mumford regularity and satiety' (preprint 2008)

Procedures:

D.4.22.1 NPos_test

Procedure from library `noether.lib` (see [Section D.4.22 \[noether.lib\]](#), [page 1181](#)).

Usage: NPos_test (I); I monomial ideal

Return: A list whose first element is 1, if i is in Noether position, 0 otherwise. The second element of this list is a list of variables ordered such that those variables are listed first, of which a power belongs to the initial ideal of i. If i is in Noether position, the method returns furthermore the dimension of i.

Assume: i is a nonzero monomial ideal.

Example:

```

LIB "noether.lib";
ring r=0,(X,Y,a,b),dp;
poly f=X^8+a*Y^4-Y;
poly g=Y^8+b*X^4-X;
poly h=diff(f,X)*diff(g,Y)-diff(f,Y)*diff(g,X);

```

```

ideal i=f,g,h;
NPos_test(i);
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ [1]:
⇒ b
⇒ [2]:
⇒ a
⇒ [3]:
⇒ Y
⇒ [4]:
⇒ X

```

D.4.22.2 modNpos_test

Procedure from library `noether.lib` (see [Section D.4.22 \[noether.lib\]](#), page 1181).

Usage: `modNpos_test(i)`; `i` an ideal

Return: 1 if `i` is in Noether position 0 otherwise.

Note: This test is a probabilistic test, and it computes the initial of the ideal modulo the prime number 2147483647 (the biggest prime less than 2^{31}).

Example:

```

LIB "noether.lib";
ring r=0,(X,Y,a,b),dp;
poly f=X^8+a*Y^4-Y;
poly g=Y^8+b*X^4-X;
poly h=diff(f,X)*diff(g,Y)-diff(f,Y)*diff(g,X);
ideal i=f,g,h;
modNpos_test(i);
⇒ // WARNING:
⇒ // The procedure is probabilistic and it computes the initial of the ide\
    al modulo the prime number 2147483647
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ [1]:
⇒ X
⇒ [2]:
⇒ Y
⇒ [3]:
⇒ b
⇒ [4]:
⇒ a

```

D.4.22.3 NPos

Procedure from library `noether.lib` (see [Section D.4.22 \[noether.lib\]](#), page 1181).

Usage: `NPos(i)`; `i` ideal

Return: A linear map `phi` such that `phi(i)` is in Noether position

Example:

```
LIB "noether.lib";
ring r=0,(X,Y,a,b),dp;
poly f=X^8+a*Y^4-Y;
poly g=Y^8+b*X^4-X;
poly h=diff(f,X)*diff(g,Y)-diff(f,Y)*diff(g,X);
ideal i=f,g,h;
NPos(i);
⇒ The dimension of the ideal is:
⇒ 1
⇒ _[1]=X
⇒ _[2]=Y
⇒ _[3]=a
⇒ _[4]=53X+27Y-75a+b and the time of this computation is: 691 /10 sec.
```

D.4.22.4 modNPos

Procedure from library `noether.lib` (see [Section D.4.22 \[noether.lib\]](#), page 1181).

Usage: `modNPos(i); i ideal`

Return: A linear map ϕ such that $\phi(i)$ is in Noether position

Note: It uses the procedure `modNpos_test` to test Noether position.

Example:

```
LIB "noether.lib";
ring r=0,(X,Y,a,b),dp;
poly f=X^8+a*Y^4-Y;
poly g=Y^8+b*X^4-X;
poly h=diff(f,X)*diff(g,Y)-diff(f,Y)*diff(g,X);
ideal i=f,g,h;
modNPos(i);
⇒ // WARNING:
⇒ // The procedure is probabilistic and it computes the initial of the ide\
  al modulo the prime number 2147483647
⇒ // WARNING:
⇒ // The procedure is probabilistic and it computes the initial of the ide\
  al modulo the prime number 2147483647
⇒ // WARNING:
⇒ // The procedure is probabilistic and it computes the initial of the ide\
  al modulo the prime number 2147483647
⇒ The dimension of the ideal is:
⇒ 1
⇒ _[1]=X
⇒ _[2]=Y
⇒ _[3]=a
⇒ _[4]=53X+27Y-75a+b and the time of this computation is: 11 /10 sec.
```

D.4.22.5 nsatiety

Procedure from library `noether.lib` (see [Section D.4.22 \[noether.lib\]](#), page 1181).

Usage: `nsatiety (i); i ideal,`

- Return:** an integer, the satiety of i .
(returns -1 if i is not homogeneous)
- Assume:** i is a homogeneous ideal of the basering $R=K[x(0)..x(n)]$.
- Theory:** The satiety, or saturation index, of a homogeneous ideal i is the least integer s such that, for all $d \geq s$, the degree d part of the ideals i and $\text{isat}=\text{sat}(i, \text{maxideal}(1))$ coincide.

Example:

```
LIB "noether.lib";
ring r=0,(t,a,b,c,d),dp;
ideal i=b4-a3d, ab3-a3c, bc4-ac3d-bcd3+ad4, c6-bc3d2-c3d3+bd5, ac5-b2c3d-ac2d3+b2d4,
nsatiety(i);
↪ sat(i)=0 and the time of this computation: 2/100sec.
```

D.4.22.6 modsatiety

Procedure from library `noether.lib` (see [Section D.4.22 \[noether.lib\]](#), page 1181).

- Usage:** `modsatiety(i); i ideal,`
- Return:** an integer, the satiety of i .
(returns -1 if i is not homogeneous)
- Assume:** i is a homogeneous ideal of the basering $R=K[x(0)..x(n)]$.
- Theory:** The satiety, or saturation index, of a homogeneous ideal i is the least integer s such that, for all $d \geq s$, the degree d part of the ideals i and $\text{isat}=\text{sat}(i, \text{maxideal}(1))$ coincide.
- Note:** This is a probabilistic procedure, and it computes the initial of the ideal modulo the prime number 2147483647 (the biggest prime less than 2^{31}).

Example:

```
LIB "noether.lib";
ring r=0,(t,a,b,c,d),dp;
ideal i=b4-a3d, ab3-a3c, bc4-ac3d-bcd3+ad4, c6-bc3d2-c3d3+bd5, ac5-b2c3d-ac2d3+b2d4,
modsatiety(i);
↪ // WARNING: The characteristic of base field must be zero.
↪ // The procedure is probabilistic and it computes the
↪ //initial ideals modulo the prime number 2147483647.
↪ msat(i)=0 and the time of this computation: 2/100sec.
```

D.4.22.7 regCM

Procedure from library `noether.lib` (see [Section D.4.22 \[noether.lib\]](#), page 1181).

- Usage:** `regCM (i); i ideal`
- Return:** the Castelnuovo-Mumford regularity of i .
(returns -1 if i is not homogeneous)
- Assume:** i is a homogeneous ideal.

Example:

```
LIB "noether.lib";
ring r=0,(t,a,b,c,d),dp;
ideal i=b4-a3d, ab3-a3c, bc4-ac3d-bcd3+ad4, c6-bc3d2-c3d3+bd5, ac5-b2c3d-ac2d3+b2d4,
regCM(i);
↪ reg(i)=7 and the time of this computation: 4 sec./100
```

D.4.22.8 modregCM

Procedure from library `noether.lib` (see [Section D.4.22 \[noether.lib\]](#), page 1181).

Usage: `modregCM(i); i ideal`

Return: an integer, the Castelnuovo-Mumford regularity of `i`.
(returns -1 if `i` is not homogeneous)

Assume: `i` is a homogeneous ideal and the characteristic of base field is zero..

Note: This is a probabilistic procedure, and it computes the initial of the ideal modulo the prime number 2147483647 (the biggest prime less than 2^{31}).

Example:

```
LIB "noether.lib";
ring r=0,(t,a,b,c,d),dp;
ideal i=b4-a3d, ab3-a3c, bc4-ac3d-bcd3+ad4, c6-bc3d2-c3d3+bd5, ac5-b2c3d-ac2d3+b2d4,
modregCM(i);
⇒ // WARNING: The characteristic of base field must be zero.
⇒ // This procedure is probabilistic and it computes the initial
⇒ //ideals modulo the prime number 2147483647
⇒ // ** redefining zz ( list l11;int zz;) noether.lib::modregCM:937
⇒ mreg(i)=7 and the time of this computation: 4sec./100
```

D.4.23 normal_lib

Library: `normal.lib`

Purpose: Normalization of Affine Rings

Authors: J. Boehm boehm@mathematik.uni-kl.de,
W. Decker decker@mathematik.uni-kl.de,
G.-M. Greuel, greuel@mathematik.uni-kl.de,
S. Laplagne, slaplagn@dm.uba.ar,
G. Pfister, pfister@mathematik.uni-kl.de,
A. Steenpass steenpass@mathematik.uni-kl.de,
S. Steidel steidel@mathematik.uni-kl.de,
P. Chini, chini@rhrk.uni-kl.de (normalConductor)

Procedures: See also: [Section D.4.12 \[integralbasis.lib\]](#), page 1116.

D.4.23.1 normal

Procedure from library `normal.lib` (see [Section D.4.23 \[normal.lib\]](#), page 1185).

Usage: `normal(id [,choose]); id = radical ideal, choose = list of options.`

Optional parameters in list `choose` (can be entered in any order):

Decomposition:

- "equidim" -> computes first an equidimensional decomposition of the input ideal, and then the normalization of each component (default).
- "prim" -> computes first the minimal associated primes of the input ideal, and then the normalization of each prime. (When the input ideal is not prime and the minimal associated primes are easy to compute, this method is usually faster than "equidim".)
- "noDeco" -> no preliminary decomposition is done. If the ideal is not equidimensional radical, output might be wrong.

- "isPrim" -> assumes that the ideal is prime. If this assumption does not hold, the output might be wrong.

- "noFac" -> factorization is avoided in the computation of the minimal associated primes;

Other:

- "useRing" -> uses the original ring ordering.

If this option is set and if the ring ordering is not global, normal will change to a global ordering only for computing radicals and prime or equidimensional decompositions.

If this option is not set, normal changes to dp ordering and performs all computations with respect to this ordering.

- "withDelta" (or "wd") -> returns also the delta invariants. Not valid for options "locNormal" and "modNormal".

If the optional parameter choose is not given or empty, only "equidim" but no other option is used.

- list("inputJ", ideal inputJ) -> takes as initial test ideal the ideal inputJ. This option is only for use in other procedures. Using this option, the result might not be the normalization.

(Option only valid for global algorithm.)

- list("inputC", ideal inputC) -> takes as initial conductor the ideal inputC. This option is only for use in other procedures. Using this option, the result might not be the normalization.

(Option only valid for global algorithm.)

Options used for computing integral basis (over rings of two variables):

- "normalCheck" -> checks only if the ring is normal. The output is 1 if the ring is normal and 0 if not.

- "var1" -> uses a polynomial in the first variable as universal denominator.

- "var2" -> uses a polynomial in the second variable as universal denominator.

- "GBRadical" -> it computes a Groebner basis of the radical ideal computed for the test ideal.

- "noGBRadical" -> it does not compute a Groebner basis of the radical ideal computed for the test ideal.

- "locNormal" -> uses locNormal procedure to compute the normalization, which implements a local-to-global algorithm (for this option it is required that the ideal I is prime).

- "modular" -> combined with "locNormal" option, it will use modNormal algorithm for the local computations.

- "modNormal" -> uses modNormal procedure to compute the normalization, which implements a modular algorithm (for this option it is required that the ideal I is prime).

- list("nPrimes", int n) -> parameter for modNormal. We consider n primes at a time until the result lifted to the rationals is correct modulo one additional prime. (default: n = 10)

- "noVerification" -> if the modular approach is used (using modNormal option or modular option in locNormal), the result will not be verified.

If the optional parameter choose is not given or empty, only "equidim" but no other option is used.

- "withRing" -> the ring structure of the normalization is computed. The number of variables in the new ring is reduced as much as possible. This is the default option, except when using modNormal or locNormal options.

Assume: The ideal must be radical, for non-radical ideals the output may be wrong (`id=radical(id)`; makes `id` radical). However, when using the "prim" option the minimal associated primes of `id` are computed first and hence `normal` computes the normalization of the radical of `id`.

Note: "isPrim" should only be used if `id` is known to be prime.

Return: If "withRing" option is set, a list, say `nor`, of size 2 (resp. 3 with option "withDelta"). Let `R` denote the basering and `id` the input ideal.

- * `nor[1]` is a list of `r` rings, where `r` is the number of associated primes `Pi` with option "prim" (resp. \geq no of equidimensional components `Pi` with option "equidim"). Each ring `Ri := nor[1][i]`, $i=1..r$, contains two ideals with given names `norid` and `normap` such that:
 - `Ri/norid` is the normalization of the i -th component, i.e. the integral closure of `R/Pi` in its field of fractions (as affine ring);
 - `normap` gives the normalization map from `R/id` to `Ri/norid` for each i .
 - the direct sum of the rings `Ri/norid`, $i=1..r$, is the normalization of `R/id` as affine algebra;
- * `nor[2]` is a list of size `r` with information on the normalization of the i -th component as module over the basering `R`:
 - `nor[2][i]` is an ideal, say `U`, in `R` such that the integral closure of `basing/Pi` is generated as module over `R` by `1/c * U`, with `c` the last element `U[size(U)]` of `U`.
- * `nor[3]` (if option "withDelta" is set) is a list of an intvec of size `r`, the delta invariants of the `r` components, and an integer, the total delta invariant of `basing/id` (-1 means infinite, and 0 that `R/Pi` resp. `R/id` is normal).

If "withRing" option is not set, a list of an ideal `U` and a polynomial `d` such that `U/d` is the normalization

Theory: We use here a general algorithm described in [G.-M.Greuel, S.Laplagne, F.Seelisch: Normalization of Rings (2009)].

The procedure computes the `R`-module structure, the algebra structure and the delta invariant of the normalization of `R/id`:

The normalization of `R/id` is the integral closure of `R/id` in its total ring of fractions. It is a finitely generated `R`-module and `nor[2]` computes `R`-module generators of it. More precisely: If `U:=nor[2][i]` and `c:=U[size(U)]`, then `c` is a non-zero divisor and `U/c` is an `R`-module in the total ring of fractions, the integral closure of `R/Pi`. Since `U[size(U)]/c` is equal to 1, `R/Pi` resp. `R/id` is contained in the integral closure.

The normalization is also an affine algebra over the ground field and `nor[1]` presents it as such. For geometric considerations `nor[1]` is relevant since the variety of the ideal `norid` in `Ri` is the normalization of the variety of the ideal `Pi` in `R`.

The delta invariant of a reduced ring `A` is $\dim_K(\text{normalization}(A)/A)$. For `A=K[x1,...,xn]/id` we call this number also the delta invariant of `id`. `nor[3]` returns the delta invariants of the components `Pi` and of `id`.

Note: To use the i -th ring type e.g.: `def R=nor[1][i]; setring R;`

Increasing/decreasing `printlevel` displays more/less comments (default: `printlevel=0`).

Implementation works also for local rings.

Not implemented for quotient rings.

If the input ideal `id` is weighted homogeneous a weighted ordering may be used together with the `useRing`-option (`qhweight(id)`; computes weights).

Example:

```

LIB "normal.lib";

D.4.23.2 locNormal

Procedure from library `normal.lib` (see [Section D.4.23 \[normal_lib\]](#), page 1185).

- Usage:** `locNormal(I [,options]);` I = prime ideal, options = list of options.
Optional parameters in list options (can be entered in any order):
modular: use a modular approach for the local computations. The number of primes is increased one at a time, starting with 2 primes, until the result stabilizes.
noVerification: if the modular approach is used, the result will not be verified.
- Assume:** I is a prime ideal (the algorithm will also work for radical ideals as long as the normal command does not detect that the ideal under consideration is not prime).
- Return:** a list of an ideal U and a universal denominator d such that U/d is the normalization.
- Remarks:** We use the local-to-global algorithm given in [1] to compute the normalization of $A = R/I$, where R is the basering.
The idea is to stratify the singular locus of A , apply the normalization algorithm given in [2] locally at each stratum, and put the local results together.
If the option modular is given, the result is returned as a probabilistic result or verified, depending on whether the option noVerification is used or not.
The normalization of A is represented as an R -module by returning a list of U and d , where U is an ideal of A and d is an element of A such that U/d is the normalization of A . In fact, U and d are returned as an ideal and a polynomial of the base ring R .

See also: [Section D.4.23 \[normal_lib\], page 1185](#).

D.4.23.3 modNormal

Procedure from library `normal.lib` (see [Section D.4.23 \[normal_lib\], page 1185](#)).

Usage: `modNormal(I, n [,options]);` I = prime ideal, n = positive integer, `options` = list of options.

Optional parameters in list `options` (can be entered in any order):

`noVerification`: do not verify the result.

`printTimings`: print timings.

`int ncores`: number of cores to be used (default = 1).

Assume: I is a prime ideal (the algorithm will also work for radical ideals as long as the normal command does not detect that the ideal under consideration is not prime).

Return: a list of an ideal U and a universal denominator d such that U/d is the normalization.

Remarks: We use the algorithm given in [1] to compute the normalization of $A = R/I$ where R is the basering. We apply the algorithm for n primes at a time until the result lifted to the rationals is correct modulo one additional prime. Depending on whether the option `noVerification` is used or not, the result is returned as a probabilistic result or verified over the rationals.

The normalization of A is represented as an R -module by returning a list of U and d , where U is an ideal of A and d is an element of A such that U/d is the normalization of A . In fact, U and d are returned as an ideal and a polynomial of the base ring R .

Example:

```

LIB "normal.lib";
ring R = 0,(x,y,z),dp;
int k = 4;
poly f = (x^(k+1)+y^(k+1)+z^(k+1))^2-4*(x^(k+1)*y^(k+1)+y^(k+1)*z^(k+1)+z^(k+1)*x^(k+1));
f = subst(f,z,3x-2y+1);
ring S = 0,(x,y),dp;
poly f = imap(R,f);
ideal i = f;
list L = modNormal(i,1,"noVerification");

```

See also: [Section D.4.12 \[integralbasis_lib\], page 1116](#).

D.4.23.4 normalP

Procedure from library `normal.lib` (see [Section D.4.23 \[normal_lib\], page 1185](#)).

Usage: `normalP(id [,choose]);` id = radical ideal, `choose` = optional list of strings.

Optional parameters in list `choose` (can be entered in any order):

"withRing", "isPrim", "noFac", "noRed", where

- "noFac" -> factorization is avoided during the computation of the minimal associated primes.

- "isPrim" -> assumes that the ideal is prime. If the assumption does not hold, output might be wrong.
- "withRing" -> the ring structure of the normalization is computed. The number of variables in the new ring is reduced as much as possible.
- "noRed" -> when computing the ring structure, no reduction on the number of variables is done, it creates one new variable for every new module generator of the integral closure in the quotient field.

Assume: The characteristic of the ground field must be positive. If the option "isPrim" is not set, the minimal associated primes of `id` are computed first and hence `normalP` computes the normalization of the radical of `id`. If option "isPrim" is set, the ideal must be a prime ideal otherwise the result may be wrong.

Return: a list, say 'nor' of size 2 (resp. 3 if "withRing" is set).
 ** If option "withRing" is not set:
 Only the module structure is computed:
 * `nor[1]` is a list of ideals I_i , $i=1..r$, in the basering R where r is the number of minimal associated prime ideals P_i of the input ideal `id`, describing the module structure:
 If I_i is given by polynomials g_1, \dots, g_k in R , then $c := g_k$ is non-zero in the ring R/P_i and $g_1/c, \dots, g_k/c$ generate the integral closure of R/P_i as R -module in the quotient field of R/P_i .
 * `nor[2]` shows the delta invariants: it is a list of an intvec of size r , the delta invariants of the r components, and an integer, the total delta invariant of R/id (-1 means infinite, and 0 that R/P_i resp. R/id is normal).
 ** If option "withRing" is set:
 The ring structure is also computed, and in this case:
 * `nor[1]` is a list of r rings.
 Each ring $R_i = \text{nor}[1][i]$, $i=1..r$, contains two ideals with given names `norid` and `normap` such that
 - R_i/norid is the normalization of R/P_i , i.e. isomorphic as K -algebra (K the ground field) to the integral closure of R/P_i in the field of fractions of R/P_i ;
 - the direct sum of the rings R_i/norid is the normalization of R/id ;
 - `normap` gives the normalization map from R to R_i/norid .
 * `nor[2]` gives the module generators of the normalization of R/P_i , it is the same as `nor[1]` if "withRing" is not set.
 * `nor[3]` shows the delta invariants, it is the same as `nor[2]` if "withRing" is not set.

Theory: `normalP` uses the Leonard-Pellikaan-Singh-Swanson algorithm (using the Frobenius) cf. [A. K. Singh, I. Swanson: An algorithm for computing the integral closure, arXiv:0901.0871].

The delta invariant of a reduced ring A is $\dim_K(\text{normalization}(A)/A)$. For $A=K[x_1, \dots, x_n]/id$ we call this number also the delta invariant of `id`. The procedure returns the delta invariants of the components P_i and of `id`.

Note: To use the i -th ring type: `def R=nor[1][i]; setring R;`
 Increasing/decreasing `printlevel` displays more/less comments (default: `printlevel = 0`).
 Not implemented for local or mixed orderings or quotient rings. For local or mixed orderings use `proc 'normal'`.
 If the input ideal `id` is weighted homogeneous a weighted ordering may be used (`qh-weight(id)`; computes weights).
 Works only in characteristic $p > 0$; use `proc normal` in char 0.

Example:

```

LIB "normal.lib";
ring r = 11,(x,y,z),wp(2,1,2);
ideal i = x*(z3 - xy4 + x2);
list nor= normalP(i); nor;
⇒
⇒ // 'normalP' computed a list, say nor, of two lists:
⇒ // To see the result, type
⇒     nor;
⇒
⇒ // * nor[1] is a list of 2 ideal(s), where each ideal nor[1][i] consists

D.4.23.5 normalC

Procedure from library `normal.lib` (see [Section D.4.23 \[normal.lib\], page 1185](#)).

Usage: `normalC(id [,choose]);` `id` = radical ideal, `choose` = optional list of string.
Optional parameters in list `choose` (can be entered in any order):
Decomposition:
- "equidim" -> computes first an equidimensional decomposition, and then the normalization of each component (default).
- "prim" -> computes first the minimal associated primes, and then the normalization of each prime.
- "noDeco" -> no preliminary decomposition is done. If the ideal is not equidimensional radical, output might be wrong.
- "isPrim" -> assumes that the ideal is prime. If the assumption does not hold, output

might be wrong.

- "noFac" -> factorization is avoided in the computation of the minimal associated primes;

Other:

- "withGens" -> the minimal associated primes P_i of id are computed and for each P_i , algebra generators of the integral closure of $\text{basering}/P_i$ are computed as elements of its quotient field;

If choose is not given or empty, the default options are used.

Assume: The ideal must be radical, for non-radical ideals the output may be wrong ($id = \text{radical}(id)$; makes id radical). However, if option "prim" is set the minimal associated primes are computed first and hence `normalC` computes the normalization of the radical of id . "isPrim" should only be used if id is known to be irreducible.

Return: a list, say `nor`, of size 2 (resp. 3 if option "withGens" is set).
 * `nor[1]` is always a of r rings, where r is the number of associated primes with option "prim" (resp. \geq no of equidimensional components with option "equidim").
 Each ring $R_i = \text{nor}[1][i]$, $i = 1..r$, contains two ideals with given names `norid` and `normap` such that
 - R_i/norid is the normalization of the i -th component, i.e. the integral closure in its field of fractions as affine ring, i.e. R_i is given in the form $K[X(1..p), T(1..q)]$, where K is the ground field; - `normap` gives the normalization map from $\text{basering}/id$ to R_i/norid for each i (the j -th element of `normap` is mapped to the j -th variable of R).
 - the direct sum of the rings R_i/norid is the normalization of $\text{basering}/id$;
 ** If option "withGens" is not set:
 * `nor[2]` shows the delta invariants: `nor[2]` is a list of an intvec of size r , the delta invariants of the r components, and an integer, the delta invariant of $\text{basering}/id$. (-1 means infinite, 0 that $\text{basering}/P_i$ resp. $\text{basering}/\text{input}$ is normal, -2 means that delta resp. delta of one of the components is not computed (which may happen if "equidim" is given).
 ** If option "withGens" is set:
 * `nor[2]` is a list of ideals $I_i = \text{nor}[2][i]$, $i = 1..r$, in the basering , generating the integral closure of $\text{basering}/P_i$ in its quotient field as K -algebra (K the ground field):
 If I_i is given by polynomials g_1, \dots, g_k , then $c := g_k$ is a non-zero divisor and the j -th variables of the ring R_i satisfies $\text{var}(j) = g_j/c$, $j = 1..k-1$, as element in the quotient field of $\text{basering}/P_i$. The g_j/g_{k+1} are K -algebra generators of the integral closure of $\text{basering}/P_i$.
 * `nor[3]` shows the delta invariant as above.

Theory: We use the Grauert-Remmert-de Jong algorithm [c.f. G.-M. Greuel, G. Pfister: A SINGULAR Introduction to Commutative Algebra, 2nd Edition. Springer Verlag (2007)].

The procedure computes the algebra structure and the delta invariant of the normalization of R/id :

The normalization is an affine algebra over the ground field K and `nor[1]` presents it as such: $R_i = K[X(1..p), T(1..q)]$ and R_i/norid is the integral closure of R/P_i ; if option "withGens" is set the $X(j)$ and $T(j)$ are expressed as quotients in the total ring of fractions. Note that the $X(j)$ and $T(j)$ generate the integral closure as K -algebra, but not necessarily as R -module (since relations of the form $X(1) = T(1) \cdot T(2)$ may have been eliminated). Geometrically the algebra structure is relevant since the variety of the ideal `norid` in R_i is the normalization of the variety of the ideal P_i in R .

The delta invariant of a reduced ring A is $\dim_K(\text{normalization}(A)/A)$. For $A=K[x_1,\dots,x_n]/\text{id}$ we call this number also the delta invariant of id . `nor[3]` returns the delta invariants of the components P_i and of id .

Note: To use the i -th ring type: `def R=nor[1][i]; setring R;`
 Increasing/decreasing `printlevel` displays more/less comments (default: `printlevel=0`).
 Not implemented for local or mixed orderings or quotient rings. For local or mixed orderings use `proc 'normal'`.
 If the input ideal id is weighted homogeneous a weighted ordering may be used (`qh-weight(id)`; computes weights).

Example:

```
LIB "normal.lib";
printlevel = printlevel+1;
ring s = 0,(x,y),dp;
ideal i = (x2-y3)*(x2+y2)*x;
list nor = normalC(i);

See also: [Section D.4.23.1 \[normal\], page 1185](#); [Section D.4.23.4 \[normalP\], page 1195](#).

D.4.23.6 HomJJ

Procedure from library `normal.lib` (see [Section D.4.23 \[normal_lib\], page 1185](#)).

Usage: HomJJ (Li); Li = list: ideal SBid, ideal id, ideal J, poly p

Assume: R = P/id, P = basering, a polynomial ring, id an ideal of P,
SBid = standard basis of id,

J = ideal of P containing the polynomial p ,
 p = nonzero divisor of R

Compute: Endomorphism ring $\text{End}_R(J) = \text{Hom}_R(J, J)$ with its ring structure as affine ring, together with the map $R \rightarrow \text{Hom}_R(J, J)$ of affine rings, where R is the quotient ring of P modulo the standard basis SBid .

Return: a list l of three objects

$l[1]$: a polynomial ring, containing two ideals, 'endid' and 'endphi'
 such that $l[1]/\text{endid} = \text{Hom}_R(J, J)$ and
 endphi describes the canonical map $R \rightarrow \text{Hom}_R(J, J)$
 $l[2]$: an integer which is 1 if phi is an isomorphism, 0 if not
 $l[3]$: an integer, = $\dim_K(\text{Hom}_R(J, J)/R)$ (the contribution to delta)
 if the dimension is finite, -1 otherwise

Note: printlevel ≥ 1 : display comments (default: printlevel=0)

Example:

```
LIB "normal.lib";
ring r = 0, (x, y), wp(2, 3);
ideal id = y^2 - x^3;
ideal J = x, y;
poly p = x;
list Li = std(id), id, J, p;
list L = HomJJ(Li);
def end = L[1]; // defines ring L[1], containing ideals endid, endphi
setring end; // makes end the basering
end;
↪ // coefficients: QQ
↪ // number of vars : 1
↪ // block 1 : ordering dp
↪ // : names T(1)
↪ // block 2 : ordering C
endid; // end/endid is isomorphic to End(r/id) as ring
↪ endid[1]=0
map psi = r, endphi; // defines the canonical map r/id -> End(r/id)
psi;
↪ psi[1]=T(1)^2
↪ psi[2]=T(1)^3
L[3]; // contribution to delta
↪ 1
```

D.4.23.7 genus

Procedure from library `normal.lib` (see [Section D.4.23 \[normal.lib\]](#), page 1185).

Return: an integer, the geometric genus $p_g = p_a - \delta$ of the projective curve defined by i , where p_a is the arithmetic genus.

Note: genus always treats projective curves and takes projective closure if input is affine 1-dim variety. delta is the sum of all local delta-invariants of the singularities, i.e. $\dim(R'/R)$, R' the normalization of the local ring R of the singularity.
 genus(I,"nor") uses the normalization to compute delta. Usually genus(I,"nor") is slower than genus(I) but sometimes not.
 genus(I,"pri") starts with a primary decomposition.

Example:

```
LIB "normal.lib";
ring r=0,(x,y),dp;
ideal i=y^9 - x^2*(x - 1)^9;
genus(i);
⇒ 0
ring r7=7,(x,y),dp;
ideal i=y^9 - x^2*(x - 1)^9;
genus(i);
⇒ 0
```

D.4.23.8 primeClosure

Procedure from library `normal.lib` (see [Section D.4.23 \[normal.lib\]](#), page 1185).

Usage: `primeClosure(L [,c]);` L a list of a ring containing a prime ideal ker, c an optional integer

Return: a list L (of size n+1) consisting of rings L[1],...,L[n] such that - L[1] is a copy of (not a reference to!) the input ring L[1] - all rings L[i] contain ideals ker, L[2],...,L[n] contain ideals phi such that
 $L[1]/\ker \rightarrow \dots \rightarrow L[n]/\ker$
 are injections given by the corresponding ideals phi, and L[n]/ker is the integral closure of L[1]/ker in its quotient field. - all rings L[i] contain a polynomial nzd such that elements of L[i]/ker are quotients of elements of L[i-1]/ker with denominator nzd via the injection phi.
 L[n+1] is the delta invariant

Note: - L is constructed by recursive calls of primeClosure itself. - c determines the choice of nzd:
 - c not given or equal to 0: first generator of the ideal SL, the singular locus of $\text{Spec}(L[i]/\ker)$
 - $c > 0$: the generator of SL with least number of monomials.

Example:

```
LIB "normal.lib";
ring R=0,(x,y),dp;
ideal I=x^4,y^4;
def K=ReesAlgebra(I)[1];          // K contains ker such that K/ker=R[It]
list L=primeClosure(K);
def R(1)=L[1];                    // L[4] contains ker, L[4]/ker is the
def R(4)=L[4];                    // integral closure of L[1]/ker
setring R(1);
R(1);
⇒ // coefficients: QQ
⇒ // number of vars : 4
⇒ //          block 1 : ordering dp
⇒ //          : names  x y U(1) U(2)
⇒ //          block 2 : ordering C
ker;
⇒ ker[1]=y^4*U(1)-x^4*U(2)
setring R(4);
R(4);
⇒ // coefficients: QQ
⇒ // number of vars : 10
```

```

⇒ //          block   1 : ordering a
⇒ //          : names   X(1) X(2) X(3) X(4) X(5) X(6) X(7) T(2) T(\
3) T(4)
⇒ //          : weights   1   1   1   1   3   2   2   1   \
1   1
⇒ //          block   2 : ordering dp
⇒ //          : names   X(1) X(2) X(3) X(4) X(5) X(6) X(7) T(2) T(\
3) T(4)
⇒ //          block   3 : ordering C
ker;
⇒ ker[1]=X(2)*X(7)-X(5)
⇒ ker[2]=X(1)*X(6)-X(5)
⇒ ker[3]=X(1)^2*X(4)-X(2)*X(6)
⇒ ker[4]=X(2)^2*X(3)-X(1)*X(7)
⇒ ker[5]=X(1)*X(4)*X(7)-X(6)^2
⇒ ker[6]=X(1)*X(2)*X(3)*X(4)-X(6)*X(7)
⇒ ker[7]=X(2)*X(3)*X(6)-X(7)^2
⇒ ker[8]=X(1)*T(3)-X(2)*T(4)
⇒ ker[9]=-X(2)*T(2)+X(1)*T(4)
⇒ ker[10]=-X(2)*T(2)+X(7)
⇒ ker[11]=-X(2)*T(4)+X(6)
⇒ ker[12]=X(6)*T(2)-X(7)*T(4)
⇒ ker[13]=X(2)*X(4)*T(2)-X(6)*T(3)
⇒ ker[14]=X(1)*X(4)-X(2)*T(3)
⇒ ker[15]=X(1)*X(4)*T(2)-X(6)*T(4)
⇒ ker[16]=X(2)*X(3)-X(1)*T(2)
⇒ ker[17]=-X(2)^2*T(2)+X(5)
⇒ ker[18]=X(3)*X(6)-X(7)*T(2)
⇒ ker[19]=X(2)*X(3)*X(4)-X(7)*T(3)
⇒ ker[20]=X(1)*X(3)*X(4)-X(7)*T(4)
⇒ ker[21]=X(2)^2*X(6)*T(4)-X(2)*X(5)*T(3)
⇒ ker[22]=T(2)^2-X(3)*T(4)
⇒ ker[23]=-X(3)*X(4)+T(2)*T(3)
⇒ ker[24]=T(3)^2-X(4)*T(4)
⇒ ker[25]=-X(3)*T(3)+T(2)*T(4)
⇒ ker[26]=-X(4)*T(2)+T(3)*T(4)
⇒ ker[27]=-X(3)*X(4)+T(4)^2

```

D.4.23.9 closureFrac

Procedure from library `normal.lib` (see [Section D.4.23 \[normal.lib\]](#), page 1185).

Usage: `closureFrac (L)`; L a list of size $n+1$ as in the result of `primeClosure`, $L[n]$ contains an additional polynomial f

Create: a list fraction of two elements of $L[1]$, such that
 $f = \text{fraction}[1] / \text{fraction}[2]$ via the injections $\phi L[i] \rightarrow L[i+1]$.

Example:

```

LIB "normal.lib";
ring R=0,(x,y),dp;
ideal ker=x2+y2;
export ker;
list L=primeClosure(R);           // We normalize R/ker

```

```

for (int i=1;i<=size(L);i++) { def R(i)=L[i]; }
setring R(2);
kill R;
phi;                                // The map R(1)-->R(2)
⇨ phi[1]=X(1)
⇨ phi[2]=X(2)
poly f=T(2);                        // We will get a representation of f
export f;
L[2]=R(2);
closureFrac(L);
setring R(1);
kill R(2);
fraction;                           // f=fraction[1]/fraction[2] via phi
⇨ [1]:
⇨      x
⇨ [2]:
⇨      y
kill R(1);

```

D.4.23.10 iMult

Procedure from library `normal.lib` (see [Section D.4.23 \[normal.lib\], page 1185](#)).

Usage: `iMult(L)`; L a list of ideals

Return: int, the intersection multiplicity of the ideals of L; if `iMult(L)` is infinite, -1 is returned.

Theory: If $r = \text{size}(L) = 2$ then $\text{iMult}(L) = \text{vdim}(\text{std}(L[1] + L[2]))$ and in general $\text{iMult}(L) = \sum \{ \text{iMult}(L[j], L_j) \mid j = 1..r-1 \}$ with L_j the intersection of $L[j+1], \dots, L[r]$. If I is the intersection of all ideals in L then we have $\text{delta}(I) = \text{delta}(L[1]) + \dots + \text{delta}(L[r]) + \text{iMult}(L)$ where $\text{delta}(I) = \text{vdim}(\text{normalisation}(R/I)/(R/I))$, R the basering.

Example:

```

LIB "normal.lib";
ring s = 23, (x,y), dp;
list L = (x-y), (x3+y2);
iMult(L);
⇨ 3
L = (x-y), (x3+y2), (x3-y4);
iMult(L);
⇨ 19

```

D.4.23.11 deltaLoc

Procedure from library `normal.lib` (see [Section D.4.23 \[normal.lib\], page 1185](#)).

Usage: `deltaLoc(f,J)`; f poly, J ideal

Assume: f is reduced bivariate polynomial; basering has exactly two variables; J is irreducible prime component of the singular locus of f (e.g., one entry of the output of `minAssGTZ(I)`; $I = \langle f, \text{jacob}(f) \rangle$).

Return: list L:

`L[1]`; int: the sum of (local) delta invariants of f at the (conjugated) singular points given by J.

L[2]; int: the sum of (local) Tjurina numbers of f at the (conjugated) singular points given by J .

L[3]; int: the sum of (local) number of branches of f at the (conjugated) singular points given by J .

Note: procedure makes use of `execute`; increasing `printlevel` displays more comments (default: `printlevel=0`).

Example:

```
LIB "normal.lib";
ring r=0,(x,y),dp;
poly f=(x2+y^2-1)^3 +27x2y2;
ideal I=f,jacob(f);
I=std(I);
list qr=minAssGTZ(I);
size(qr);
⇒ 6
// each component of the singular locus either describes a cusp or a pair
// of conjugated nodes:
deltaLoc(f,qr[1]);
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 2
⇒ [3]:
⇒ 1
deltaLoc(f,qr[2]);
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 2
⇒ [3]:
⇒ 1
deltaLoc(f,qr[3]);

See also: [Section D.6.15.12 \[delta\], page 1735](#); [Section D.6.20.15 \[tjurina\], page 1768](#).

D.4.23.12 locAtZero

Procedure from library `normal.lib` (see [Section D.4.23 \[normal.lib\], page 1185](#)).

Usage: `locAtZero(I); I = ideal`

Return: `int`, 1 if `I` has only one point which is located at zero, 0 otherwise

Assume: `I` is given as a standard bases in the basering

Note: only useful in affine rings, in local rings `vdim` does the check

Example:

```

LIB "normal.lib";
ring r = 0,(x,y,z),dp;
poly f = z5+y4+x3+xyz;
ideal i = jacob(f),f;
i=std(i);
locAtZero(i);
↳ 1
i= std(i*ideal(x-1,y,z));
locAtZero(i);
↳ 0

```

D.4.23.13 norTest

Procedure from library `normal.lib` (see [Section D.4.23 \[normal.lib\], page 1185](#)).

Assume: `nor` is the output of `normal(i)` (any options) or `normalP(i,"withRing")` or `normalC(i)` (any options).
In particular, the ring `nor[1][1]` contains the ideal `norid` and the map `normap: basering/i → nor[1][1]/norid`.

Return: an intvec `v` such that:

```

v[1] = 1 if the normap is injective and 0 otherwise
v[2] = 1 if the normap is finite and 0 otherwise
v[3] = 1 if nor[1][1]/norid is normal and 0 otherwise

```

If `n=1` (resp `n=2`) only `v[1]` (resp. `v[2]`) is computed and returned

Theory: The procedure can be used to test whether the computation of the normalization was correct: `basering/i → nor[1][1]/norid` is the normalization of `basering/i` if and only if `v=1,1,0`.

Note: For big examples it can be hard to fully test correctness; the partial test `norTest(i,nor,2)` is usually fast

Example:

```

LIB "normal.lib";
int prl = printlevel;
printlevel = -1;
ring r = 0,(x,y),dp;
ideal i = (x-y^2)^2 - y*x^3;
list nor = normal(i);
norTest(i,nor);                //1,1,1 means that normal was correct
⇨ 1
⇨ 1
⇨ 1,1,1
nor = normalC(i);
norTest(i,nor);                //1,1,1 means that normal was correct
⇨ 1
⇨ 1
⇨ 1,1,1
ring s = 2,(x,y),dp;
ideal i = (x-y^2)^2 - y*x^3;
nor = normalP(i,"withRing");
norTest(i,nor);                //1,1,1 means that normalP was correct
⇨ 1
⇨ 1
⇨ 1,1,1
printlevel = prl;

```

D.4.23.14 getSmallest

Procedure from library `normal.lib` (see [Section D.4.23 \[normal.lib\], page 1185](#)).

Usage: `getSmallest(J)`; J is an ideal.

Return: the generator of J of smallest degree. If there are more than one, it chooses the one with smallest number of monomials.

Note: It looks only at the generator of J , not at all the polynomials in the ideal. It is intended mainly to compute a good universal denominator in the normalization algorithms.

Example:

```

LIB "normal.lib";
printlevel = printlevel+1;
ring s = 0,(x,y),dp;
ideal J = x^3-y, y^5, x^2-y^2+1;
getSmallest(J);
⇨ x^2-y^2+1
printlevel = printlevel-1;

```

D.4.23.15 getOneVar

Procedure from library `normal.lib` (see [Section D.4.23 \[normal.lib\], page 1185](#)).

Usage: `getOneVar(J, vari)`; J is a 0-dimensional ideal, $vari$ is an integer.

Return: a polynomial of J in the variable indicated by $vari$ of smallest degree.

Note: Works only over rings of two variables.
It is intended mainly as an auxiliary procedure for computing integral bases.

Example:

```
LIB "normal.lib";
printlevel = printlevel+1;
ring s = 0,(x,y),dp;
ideal J = x3-y, y3;
getOneVar(J, 1);
  ↪ x9
printlevel = printlevel-1;
```

D.4.23.16 changeDenominator

Procedure from library `normal.lib` (see [Section D.4.23 \[normal.lib\]](#), page 1185).

Usage: `changeDenominator(U1, c1, c2, I);` U1 and I ideals, c1 and c2 polynomials.

Return: an ideal U2 such that the A-modules $1/c1 * U1$ and $1/c2 * U2$ are equal, where $A = R/I$ and R is the basering.

Note: It assumes that such U2 exists. It is intended mainly as an auxiliary procedure in the normalization algorithms.

Example:

```
LIB "normal.lib";
ring s = 0,(x,y),dp;
ideal I = y5-y4x+4y2x2-x4;
ideal U1 = normal(I)[2][1];
  ↪
  ↪ // 'normal' created a list, say nor, of two elements.
  ↪ // To see the list type
  ↪     nor;
  ↪
  ↪ // * nor[1] is a list of 1 ring(s).
  ↪ // To access the i-th ring nor[1][i], give it a name, say Ri, and type
  ↪     def R1 = nor[1][1]; setring R1; norid; normap;
  ↪ // For the other rings type first (if R is the name of your base ring)
  ↪     setring R;
  ↪ // and then continue as for R1.
  ↪ // Ri/norid is the affine algebra of the normalization of R/P_i where
  ↪ // P_i is the i-th component of a decomposition of the input ideal id
  ↪ // and normap the normalization map from R to Ri/norid.
  ↪
  ↪ // * nor[2] is a list of 1 ideal(s). Let ci be the last generator
  ↪ // of the ideal nor[2][i]. Then the integral closure of R/P_i is
  ↪ // generated as R-submodule of the total ring of fractions by
  ↪ // 1/ci * nor[2][i].
poly c1 = U1[4];
U1;c1;
  ↪ U1[1]=xy2
```

```

⇒ U1[2]=x2y
⇒ U1[3]=x3
⇒ U1[4]=y3
⇒ y3
// 1/c1 * U1 is the normalization of I.
ideal U2 = changeDenominator(U1, c1, x3, I);
U2;
⇒ U2[1]=-xy3+y4+4x2y
⇒ U2[2]=-x2y2+xy3+4x3
⇒ U2[3]=-x3y+x2y2-4xy3+4y4+16x2y
⇒ U2[4]=x3
// 1/x3 * U2 is also the normalization of I, but with a different denominator.

```

D.4.23.17 normalConductor

Procedure from library `normal.lib` (see [Section D.4.23 \[normal.lib\]](#), page 1185).

Usage: `normalConductor(I); I ideal`

Assume: `I` is a radical ideal

Return: the conductor of R/I as ideal in R

Remarks: The procedure makes use of the minimal primes and the generators of the normalization given by the normalization algorithm.

Note: the optional parameter can be used if the normalization has already been computed. If a list `L` contains the output of the procedure `normal` (with options `prim`, `wd` and `using` if the ring has a mixed ordering), apply `normalConductor(I,L)`

Example:

```

LIB "normal.lib";
////////////////////////////////////
// Computation of small conductor ideals //
////////////////////////////////////
ring R = 0,(x,y,z),ds;
ideal I = x2y2 - z;
normalConductor(I);
⇒ _[1]=1
// The conductor is the whole ring - so the ring is normal
// We can also see this using the delta invariant:
curveDeltaInv(I);
⇒ 0
ring S = 0,(a,b,c),dp;
ideal J = abc;
normalConductor(J);
⇒ _[1]=bc
⇒ _[2]=ac
⇒ _[3]=ab
// The conductor is not the whole ring - so it is not normal
// We can also see this using the delta invariant, which is even infinite
curveDeltaInv(J);
⇒ -1
kill R,S;
////////////////////////////////////
// Computation of a bigger example //

```

```

////////////////////////////////////
ring R = 0,(x,y,z,t),ds;
ideal I = xyz - yzt, x2y3 - z2t4;
I = std(radical(I));
// Ideal I
I;
⇒ I[1]=x2y-xyt
⇒ I[2]=xyz-yzt
⇒ I[3]=xzt-zt2
⇒ I[4]=xy3-z2t3
⇒ I[5]=y3zt-z3t3
// Conductor
normalConductor(I);
⇒ _[1]=xy
⇒ _[2]=xz-zt
⇒ _[3]=yt
⇒ _[4]=x2t-xt2
⇒ _[5]=zt2
⇒ _[6]=y3z

```

See also: [Section D.4.5.2 \[curveConductorMult\]](#), page 1050.

D.4.23.18 isNormal

Procedure from library `normal.lib` (see [Section D.4.23 \[normal.lib\]](#), page 1185).

Usage: `isNormal(I)`; `I` ideal.

Return: 1 if R/I is normal and 0 if R/I is not normal, where R is the basering.

Example:

```

LIB "normal.lib";
ring R = 0, (x,y), dp;
ideal I1 = x2 - y3;
isNormal(I1);
⇒ 0
ideal I2 = x - y3;
isNormal(I2);
⇒ 1

```

D.4.24 normaliz.lib

Library: `normaliz.lib`

Purpose: Provides an interface for the use of Normaliz 3.10.0 or newer within SINGULAR.

Authors: Winfried Bruns, wbruns@uos.de
 Christof Soeger, Christof.Soeger@Uni-Osnabrueck.de

Overview: The library `normaliz.lib` provides an interface for the use of Normaliz 3.10.0 or newer within SINGULAR. The exchange of data is via files. In addition to the top level functions that aim at objects of type `ideal` or `ring`, several other auxiliary functions allow the user to apply Normaliz to data of type `intmat`. Options such as computationn goals or algorithmic variants can be activated. To some extent, SINGULAR can therefore be used as an environment for interactive access to Normaliz.

Please see the `Normaliz.pdf` (included in the Normaliz distribution) for a more extensive documentation of Normaliz.

Normaliz allows the use of a grading. In the Singular functions that access Normaliz the parameter grading is an intvec that assigns a (not necessarily positive) degree to every variable of the ambient polynomial ring. But it must give positive degrees to the generators given to the function.

Singular and Normaliz exchange data via files. The input files use the Normaliz 3 syntax. These files are automatically created and erased behind the scenes. As long as one wants to use only the ring-theoretic functions there is no need for file management. Note that the numerical invariants computed by Normaliz can be accessed in this "automatic file mode".

However, if Singular is used as a frontend for Normaliz or the user wants to inspect data not automatically returned to Singular, then an explicit filename and a path can be specified for the exchange of data. Moreover, the library provides functions for access to these files. Deletion of the files is left to the user. (Not all output files of Normaliz can be read by this library.)

Use of this library requires the program Normaliz $\geq 3.10.0$ to be installed. You can download it from <https://github.com/Normaliz/Normaliz/releases>. Please make sure that the executable is in the search path or use `setNmzExecPath` (Section D.4.24.23 [setNmzExecPath], page 1231).

Procedures:

D.4.24.1 intclToricRing

Procedure from library `normaliz.lib` (see Section D.4.24 [normaliz.lib], page 1213).

Usage: `intclToricRing(ideal I);`
 `intclToricRing(ideal I, intvec grading);`

Return: The toric ring S is the subalgebra of the basering generated by the leading monomials of the elements of I (considered as a list of polynomials). The function computes the integral closure T of S in the basering and returns an ideal listing the algebra generators of T over the coefficient field.
 The function returns the input ideal I if an option blocking the computation of Hilbert bases has been activated. However, in this case some numerical invariants are computed, and some other data may be contained in files that you can read into Singular (see Section D.4.24.15 [showNuminvs], page 1226, Section D.4.24.16 [exportNuminvs], page 1226).

Note: A mathematical remark: the toric ring depends on the list of monomials given, and not only on the ideal they generate!

Example:

```
LIB "normaliz.lib";
ring R=37,(x,y,t),dp;
ideal I=x3,x2y,y3;
intclToricRing(I);
↪ _[1]=y
↪ _[2]=x
showNuminvs();
↪ hilbert_basis_elements : 2
```

```

⇒ number_extreme_rays : 2
⇒ dim_max_subspace : 0
⇒ embedding_dim : 3
⇒ rank : 2
⇒ external_index : 1
⇒ internal_index : 3
⇒ number_support_hyperplanes : 2
⇒ size_triangulation : 1
⇒ sum_dets : 1
⇒ integrally_closed : 0
⇒ inhomogeneous : 0
⇒ graded : 1
⇒ degree_1_elements : 2
⇒ grading : 1,1,0
⇒ grading_denom : 1
⇒ multiplicity : 1
⇒ multiplicity_denom : 1
⇒ hilbert_series_num : 1
⇒ hilbert_series_denom : 1,1
⇒ class_group : 0
//now the same example with another grading
intvec grading = 2,3,1;
intc1ToricRing(I,grading);
⇒ _[1]=x
⇒ _[2]=y
showNuminvs();
⇒ hilbert_basis_elements : 2
⇒ number_extreme_rays : 2
⇒ dim_max_subspace : 0
⇒ embedding_dim : 3
⇒ rank : 2
⇒ external_index : 1
⇒ internal_index : 3
⇒ number_support_hyperplanes : 2
⇒ size_triangulation : 1
⇒ sum_dets : 1
⇒ integrally_closed : 0
⇒ inhomogeneous : 0
⇒ graded : 1
⇒ degree_1_elements : 0
⇒ grading : 2,3,1
⇒ grading_denom : 1
⇒ multiplicity : 1
⇒ multiplicity_denom : 6
⇒ hilbert_series_num : 1,-1,1
⇒ hilbert_series_denom : 1,6
⇒ class_group : 0

```

See also: [Section D.4.24.5 \[ehrhartRing\]](#), page 1218; [Section D.4.24.6 \[intc1MonIdeal\]](#), page 1219; [Section D.4.24.2 \[normalToricRing\]](#), page 1215.

D.4.24.2 normalToricRing

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

- Usage:** `normalToricRing(ideal I);`
`normalToricRing(ideal I, intvec grading);`
- Return:** The toric ring S is the subalgebra of the basering generated by the leading monomials of the elements of I (considered as a list of polynomials). The function computes the normalisation T of S and returns an ideal listing the algebra generators of T over the coefficient field.
- The function returns the input ideal I if one of the options blocking the computation of Hilbert bases has been activated. However, in this case some numerical invariants are computed, and some other data may be contained in files that you can read into Singular (see [Section D.4.24.15 \[showNuminvs\]](#), page 1226, [Section D.4.24.16 \[exportNuminvs\]](#), page 1226).
- Note:** A mathematical remark: the toric ring depends on the list of monomials given, and not only on the ideal they generate!

Example:

```
LIB "normaliz.lib";
ring R = 37,(x,y,t),dp;
ideal I = x3,x2y,y3;
normalToricRing(I);
↦ _[1]=y3
↦ _[2]=xy2
↦ _[3]=x2y
↦ _[4]=x3
```

See also: [Section D.4.24.5 \[ehrhartRing\]](#), page 1218; [Section D.4.24.6 \[intelMonIdeal\]](#), page 1219; [Section D.4.24.1 \[intelToricRing\]](#), page 1214; [Section D.4.24.3 \[normalToricRingFromBinomials\]](#), page 1216; [Section D.4.24.4 \[toricRingFromBinomials\]](#), page 1217.

D.4.24.3 normalToricRingFromBinomials

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

- Usage:** `normalToricRingFromBinomials(ideal I);`
`normalToricRingFromBinomials(ideal I, intvec grading);`
- Return:** The ideal I is generated by binomials of type $X^a - X^b$ (multiindex notation) in the surrounding polynomial ring $K[X] = K[X_1, \dots, X_n]$. The binomials represent a congruence on the monoid Z^n with residue monoid M . Let N be the image of M in $\text{gp}(M)/\text{torsion}$. Then N is universal in the sense that every homomorphism from M to an affine monoid factors through N . If I is a prime ideal, then $K[N] = K[X]/I$. In general, $K[N] = K[X]/P$ where P is the unique minimal prime ideal of I generated by binomials of type $X^a - X^b$.
- The function computes the normalization of $K[N]$ and returns a newly created polynomial ring of the same Krull dimension, whose variables are $x(1), \dots, x(n-r)$, where r is the rank of the matrix with rows $a-b$. (In general there is no canonical choice for such an embedding.) Inside this polynomial ring there is an ideal I which lists the algebra generators of the normalization of $K[N]$.

The function returns the input ideal I if an option blocking the computation of Hilbert bases has been activated.

However, in this case some numerical invariants are computed, and some other data may be contained in files that you can read into Singular (see [Section D.4.24.15 \[showNuminvs\]](#), page 1226, [Section D.4.24.16 \[exportNuminvs\]](#), page 1226).

Example:

```

LIB "normaliz.lib";
ring R = 37, (u,v,w,x,y,z), dp;
ideal I = u2v-xyz, ux2-wyz, uvw-y2z;
def S = normalToricRingFromBinomials(I);
setring S;
I;
↪ I[1]=x(3)
↪ I[2]=x(1)
↪ I[3]=x(2)*x(3)^3
↪ I[4]=x(1)*x(2)*x(3)^2
↪ I[5]=x(1)^2*x(2)*x(3)
↪ I[6]=x(1)^3*x(2)
↪ I[7]=x(1)*x(2)^2*x(3)^4
↪ I[8]=x(1)^2*x(2)^2*x(3)^3
↪ I[9]=x(1)^2*x(2)^3*x(3)^5

```

See also: [Section D.4.24.5 \[ehrhartRing\]](#), page 1218; [Section D.4.24.6 \[intelMonIdeal\]](#), page 1219; [Section D.4.24.1 \[intelToricRing\]](#), page 1214; [Section D.4.24.2 \[normalToricRing\]](#), page 1215.

D.4.24.4 toricRingFromBinomials

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `toricRingFromBinomials(ideal I);`
 `toricRingFromBinomials(ideal I, intvec grading);`

Return: The ideal I is generated by binomials of type $X^a - X^b$ (multiindex notation) in the surrounding polynomial ring $K[X] = K[X_1, \dots, X_n]$. The binomials represent a congruence on the monoid Z^n with residue monoid M . Let N be the image of M in $\text{gp}(M)/\text{torsion}$. Then N is universal in the sense that every homomorphism from M to an affine monoid factors through N . If I is a prime ideal, then $K[N] = K[X]/I$. In general, $K[N] = K[X]/P$ where P is the unique minimal prime ideal of I generated by binomials of type $X^a - X^b$.

The function computes $K[N]$ and returns a newly created polynomial ring of the same Krull dimension, whose variables are $x(1), \dots, x(n-r)$, where r is the rank of the matrix with rows $a - b$. (In general there is no canonical choice for such an embedding.)

The function returns the input ideal I if an option blocking the computation of Hilbert bases has been activated.

However, in this case some numerical invariants are computed, and some other data may be contained in files that you can read into Singular (see [Section D.4.24.15 \[showN-uminvs\]](#), page 1226, [Section D.4.24.16 \[exportNuminvs\]](#), page 1226).

Example:

```

LIB "normaliz.lib";
ring R = 37, (u,v,w,x,y,z), dp;
ideal I = u2v-xyz, ux2-wyz, uvw-y2z;
def S = toricRingFromBinomials(I);
setring S;
I;
↪ I[1]=x(3)
↪ I[2]=x(1)

```

```

↪ I[3]=x(2)*x(3)^3
↪ I[4]=x(1)*x(2)*x(3)^2
↪ I[5]=x(1)^3*x(2)
↪ I[6]=x(1)^2*x(2)^3*x(3)^5

```

See also: [Section D.4.24.3 \[normalToricRingFromBinomials\]](#), page 1216; [Section D.4.24.4 \[toricRingFromBinomials\]](#), page 1217.

D.4.24.5 ehrhartRing

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `ehrhartRing(ideal I);`

Return: The exponent vectors of the leading monomials of the elements of `I` are considered as points of a lattice polytope `P`.

The Ehrhart ring of a (lattice) polytope `P` is the monoid algebra defined by the monoid of lattice points in the cone over the polytope `P`; see Bruns and Gubeladze, *Polytopes, Rings, and K-theory*, Springer 2009, pp. 228, 229.

The function returns a list of ideals:

(i) If the last ring variable is not used by the monomials, it is treated as the auxiliary variable of the Ehrhart ring. The function returns two ideals, the first containing the monomials representing all the lattice points of the polytope, the second containing the algebra generators of the Ehrhart ring over the coefficient field.

(ii) If the last ring variable is used by the monomials, the list returned contains only one ideal, namely the monomials representing the lattice points of the polytope.

The function returns the a list containing the input ideal `I` if an option blocking the computation of the Hilbert basis has been activated. However, in this case some numerical invariants are computed, and some other data may be contained in files that you can read into Singular (see [Section D.4.24.15 \[showNuminvs\]](#), page 1226, [Section D.4.24.16 \[exportNuminvs\]](#), page 1226).

Note: A mathematical remark: the Ehrhart ring depends on the list of monomials given, and not only on the ideal they generate!

Example:

```

LIB "normaliz.lib";
ring R=37,(x,y,t),dp;
ideal J=x3,x2y,y3,xy2t7;
ehrhartRing(J);
↪ [1]:
↪   _[1]=y3
↪   _[2]=xy2
↪   _[3]=xy2t
↪   _[4]=xy2t2
↪   _[5]=xy2t3
↪   _[6]=xy2t4
↪   _[7]=xy2t5
↪   _[8]=xy2t6
↪   _[9]=xy2t7
↪   _[10]=x2y
↪   _[11]=x2yt
↪   _[12]=x2yt2
↪   _[13]=x2yt3

```

\mapsto `_ [14]=x3`

See also: [Section D.4.24.6 \[intclMonIdeal\]](#), page 1219; [Section D.4.24.1 \[intclToricRing\]](#), page 1214; [Section D.4.24.2 \[normalToricRing\]](#), page 1215.

D.4.24.6 intclMonIdeal

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `intclMonIdeal(ideal I);`
 `intclMonIdeal(ideal I, intvec grading);`

Return: The exponent vectors of the leading monomials of the elements of `I` are considered as generators of a monomial ideal for which the normalization of its Rees algebra is computed. For a Definition of the Rees algebra (or Rees ring) see Bruns and Herzog, Cohen-Macaulay rings, Cambridge University Press 1998, p. 182.

The function returns a list of ideals:

(i) If the last ring variable is not used by the monomials, it is treated as the auxiliary variable of the Rees algebra. The function returns two ideals, the first containing the monomials generating the integral closure of the monomial ideal, the second containing the algebra generators of the normalization of the Rees algebra.

(ii) If the last ring variable is used by the monomials, the list returned contains only one ideal, namely the monomials generating the integral closure of the ideal.

The function returns the a list containing the input ideal `I` if an option blocking the computation of Hilbert bases has been activated. However, in this case some numerical invariants are computed, and some other data may be contained in files that you can read into Singular (see [Section D.4.24.15 \[showNuminvs\]](#), page 1226, [Section D.4.24.16 \[exportNuminvs\]](#), page 1226).

Example:

```
LIB "normaliz.lib";
ring R=0,(x,y,z,t),dp;
ideal I=x^2,y^2,z^3;
list l=intclMonIdeal(I);
l[1]; // integral closure of I
 $\mapsto$  _ [1]=z3
 $\mapsto$  _ [2]=yz2
 $\mapsto$  _ [3]=y2
 $\mapsto$  _ [4]=xz2
 $\mapsto$  _ [5]=xy
 $\mapsto$  _ [6]=x2
l[2]; // monomials generating the integral closure of the Rees algebra
 $\mapsto$  _ [1]=z
 $\mapsto$  _ [2]=z3t
 $\mapsto$  _ [3]=y
 $\mapsto$  _ [4]=yz2t
 $\mapsto$  _ [5]=y2t
 $\mapsto$  _ [6]=x
 $\mapsto$  _ [7]=xz2t
 $\mapsto$  _ [8]=xyt
 $\mapsto$  _ [9]=x2t
```

See also: [Section D.4.24.5 \[ehrhartRing\]](#), page 1218; [Section D.4.24.1 \[intclToricRing\]](#), page 1214; [Section D.4.24.2 \[normalToricRing\]](#), page 1215.

D.4.24.7 definingBinomialIdeal

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `definingBinomialIdeal(ideal I);`

Return: The toric ring S is the subalgebra of the basering generated by the leading monomials of the elements of I (considered as a list of polynomials). The function computes the defining binomial ideal J of S with respect to the generators and returns it, together with J . D See example.

Note: A mathematical remark: the toric ring depends on the list of monomials given, and not only on the ideal they generate! This function requires the previous setting of an `NmzFilename`. The function does not delete the written files.

Example:

```
LIB "normaliz.lib";
ring R = 37,(x,y,z,w),dp;
ideal I = x4,x3y,x2y2,xy3,y4;
setNmzFilename("binomials");
def S = definingBinomialIdeal(I);
↪ 1
↪ 1
setring S;
J;
↪ J[1]=-x(3)*x(4)+x(2)*x(5)
↪ J[2]=-x(2)*x(4)+x(1)*x(5)
↪ J[3]=x(2)*x(3)-x(1)*x(4)
↪ J[4]=-x(2)^2+x(1)*x(3)
↪ J[5]=-x(4)^2+x(3)*x(5)
↪ J[6]=x(3)^2-x(2)*x(4)
```

See also: [Section D.4.24.3 \[normalToricRingFromBinomials\]](#), page 1216.

D.4.24.8 latticeIdeal

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `latticeIdeal(ideal I);`

Return: Returns the lattice ideal defined by the elements of I which have to be binomials. The lattice ideal is the restriction to the polynomial ring of the ideal of the Laurent polynomial ring generated by I

Note: This function requires the previous setting of an `NmzFilename`. The function does not delete the written files.

Example:

```
LIB "normaliz.lib";
setNmzFilename("binomials");
ring S = 37,(u,v,w,x,y,z),dp;
ideal I = u2-v2, x2-y2, y2-vw, z2-xy;
latticeIdeal(I);
↪ 1
↪ 1
↪ _[1]=x2-y2
```

```

↳ _[2]=u2-v2
↳ _[3]=-xy+z2
↳ _[4]=vw-y2

```

See also: [Section D.4.24.34 \[intmat2binomials\]](#), page 1236.

D.4.24.9 groebnerBasis

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `groebnerBasis(ideal I);`

Return: Returns a Gröbner basis of the lattice ideal defined by the elements of `I` which have to be binomials. The lattice ideal is the restriction to the polynomial ring of the ideal of the Laurent polynomial ring generated by `I`. The default monomial order is `DegRevLex` where `Deg` is the total degree on the ambient polynomial ring. `Lex` and `DegLex` orders can be chosen via options.

Note: This function requires the previous setting of an `NmzFilename`. The function does not delete the written files.

Example:

```

LIB "normaliz.lib";
setNmzFilename("binomials");
ring S = 37, (u,v,w,x,y,z), dp;
ideal I = u2-v2, x2-y2, y2-vw, z2-xy;
groebnerBasis(I);
↳ _[1]=xy-z2
↳ _[2]=x2-y2
↳ _[3]=vw-y2
↳ _[4]=u2-v2
↳ _[5]=y3-xz2
setNmzOption("lex",1);
↳ 1
groebnerBasis(I);
↳ _[1]=y4-z4
↳ _[2]=-y3+xz2
↳ _[3]=xy-z2
↳ _[4]=x2-y2
↳ _[5]=vw-y2
↳ _[6]=u2-v2
setNmzOption("lex",0);
↳ 1

```

See also: [Section D.4.24.8 \[latticeIdeal\]](#), page 1220.

D.4.24.10 torusInvariants

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `torusInvariants(intmat A);`
`torusInvariants(intmat A, intvec grading);`

Return: Returns an ideal representing the list of monomials generating the ring of invariants as an algebra over the coefficient field. R^T .
The function returns the ideal given by the input matrix `A` if one of the options `supp`, `triang`, `volume`, or `hseries` has been activated. However, in this case some numerical

invariants are computed, and some other data may be contained in files that you can read into Singular (see [Section D.4.24.15 \[showNuminvs\]](#), page 1226, [Section D.4.24.16 \[exportNuminvs\]](#), page 1226).

Background:

Let $T = (K^*)^r$ be the r -dimensional torus acting on the polynomial ring $R = K[X_1, \dots, X_n]$ diagonally. Such an action can be described as follows: there are integers $a_{i,j}$, $i = 1, \dots, r$, $j = 1, \dots, n$, such that $(\lambda_1, \dots, \lambda_r) \in T$ acts by the substitution

$$X_j \mapsto \lambda_1^{a_{1,j}} \cdots \lambda_r^{a_{r,j}} X_j, \quad j = 1, \dots, n.$$

In order to compute the ring of invariants R^T one must specify the matrix $A = (a_{i,j})$.

Example:

```
LIB "normaliz.lib";
ring R=0,(x,y,z,w),dp;
intmat E[2][4] = -1,-1,2,0, 1,1,-2,-1;
torusInvariants(E);
map _[1]=y2z
map _[2]=xyz
map _[3]=x2z
```

See also: [Section D.4.24.12 \[diagInvariants\]](#), page 1223; [Section D.4.24.11 \[finiteDiagInvariants\]](#), page 1222; [Section D.4.24.14 \[intersectionValRingIdeals\]](#), page 1225; [Section D.4.24.13 \[intersectionValRings\]](#), page 1224.

D.4.24.11 finiteDiagInvariants

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `finiteDiagInvariants(intmat U);`
 `finiteDiagInvariants(intmat U, intvec grading);`

Return: This function computes the ring of invariants of a finite abelian group G acting diagonally on the surrounding polynomial ring $K[X_1, \dots, X_n]$. The group is the direct product of cyclic groups generated by finitely many elements g_1, \dots, g_w . The element g_i acts on the indeterminate X_j by $g_i(X_j) = \lambda_i^{u_{ij}} X_j$ where λ_i is a primitive root of unity of order equal to $\text{ord}(g_i)$. The ring of invariants is generated by all monomials satisfying the system $u_{i1}a_1 + \dots + u_{in}a_n \equiv 0 \pmod{\text{ord}(g_i)}$, $i = 1, \dots, w$. The input to the function is the $w \times (n+1)$ matrix U with rows $u_{i1} \dots u_{in} \text{ord}(g_i)$, $i = 1, \dots, w$. The output is a monomial ideal listing the algebra generators of the subalgebra of invariants $R^G = \{f \in R : g_i f = f \text{ for all } i = 1, \dots, w\}$.

The function returns the ideal given by the input matrix C if one of the options `supp`, `triang`, `volume`, or `hseries` has been activated. However, in this case some numerical invariants are computed, and some other data may be contained in files that you can read into Singular (see [Section D.4.24.15 \[showNuminvs\]](#), page 1226, [Section D.4.24.16 \[exportNuminvs\]](#), page 1226).

Note:

Example:

```
LIB "normaliz.lib";
ring R = 0,(x,y,z,w),dp;
intmat C[2][5] = 1,1,1,1,5, 1,0,2,0,7;
```

```

finiteDiagInvariants(C);
↳ _[1]=w5
↳ _[2]=z7w3
↳ _[3]=z14w
↳ _[4]=z35
↳ _[5]=yw4
↳ _[6]=yz7w2
↳ _[7]=yz14
↳ _[8]=y2w3
↳ _[9]=y2z7w
↳ _[10]=y3w2
↳ _[11]=y3z7
↳ _[12]=y4w
↳ _[13]=y5
↳ _[14]=xz3w
↳ _[15]=xz24
↳ _[16]=xyz3
↳ _[17]=x2z13
↳ _[18]=x3z2
↳ _[19]=x5zw4
↳ _[20]=x5yzw3
↳ _[21]=x5y2zw2
↳ _[22]=x5y3zw
↳ _[23]=x5y4z
↳ _[24]=x7w3
↳ _[25]=x7yw2
↳ _[26]=x7y2w
↳ _[27]=x7y3
↳ _[28]=x12zw2
↳ _[29]=x12yzw
↳ _[30]=x12y2z
↳ _[31]=x14w
↳ _[32]=x14y
↳ _[33]=x19z
↳ _[34]=x35

```

See also: [Section D.4.24.12 \[diagInvariants\]](#), page 1223; [Section D.4.24.14 \[intersectionValRingIdeals\]](#), page 1225; [Section D.4.24.13 \[intersectionValRings\]](#), page 1224; [Section D.4.24.10 \[torusInvariants\]](#), page 1221.

D.4.24.12 diagInvariants

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `diagInvariants(intmat A, intmat U);`
 `diagInvariants(intmat A, intmat U, intvec grading);`

Return: This function computes the ring of invariants of a diagonalizable group $D = T \times G$ where T is a torus and G is a finite abelian group, both acting diagonally on the polynomial ring $K[X_1, \dots, X_n]$. The group actions are specified by the input matrices A and U . The first matrix specifies the torus action, the second the action of the finite group. See `torusInvariants` and `finiteDiagInvariants` for more detail. The output is a monomial ideal listing the algebra generators of the subalgebra of invariants.

The function returns the ideal given by the input matrix A if one of the options **supp**, **triang**, **volume**, or **hseries** has been activated. However, in this case some numerical invariants are computed, and some other data may be contained in files that you can read into Singular (see [Section D.4.24.15 \[showNuminvs\]](#), page 1226, [Section D.4.24.16 \[exportNuminvs\]](#), page 1226).

Example:

```
LIB "normaliz.lib";
ring R=0,(x,y,z,w),dp;
intmat E[2][4] = -1,-1,2,0, 1,1,-2,-1;
intmat C[2][5] = 1,1,1,1,5, 1,0,2,0,7;
diagInvariants(E,C);
↪ _[1]=y70z35
↪ _[2]=xy19z10
↪ _[3]=x4y6z5
↪ _[4]=x15y5z10
↪ _[5]=x26y4z15
↪ _[6]=x37y3z20
↪ _[7]=x48y2z25
↪ _[8]=x59yz30
↪ _[9]=x70z35
```

See also: [Section D.4.24.11 \[finiteDiagInvariants\]](#), page 1222; [Section D.4.24.14 \[intersectionValRingIdeals\]](#), page 1225; [Section D.4.24.13 \[intersectionValRings\]](#), page 1224; [Section D.4.24.10 \[torusInvariants\]](#), page 1221.

D.4.24.13 intersectionValRings

Procedure from library **normaliz.lib** (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `intersectionValRings(intmat V, intvec grading);`

Return: The function returns a monomial ideal, to be considered as the list of monomials generating S as an algebra over the coefficient field.

Background:

A discrete monomial valuation v on $R = K[X_1, \dots, X_n]$ is determined by the values $v(X_j)$ of the indeterminates. This function computes the subalgebra $S = \{f \in R : v_i(f) \geq 0, i = 1, \dots, r\}$ for several such valuations $v_i, i = 1, \dots, r$. It needs the matrix $V = (v_i(X_j))$ as its input.

The function returns the ideal given by the input matrix V if one of the options **supp**, **triang**, **volume**, or **hseries** has been activated. However, in this case some numerical invariants are computed, and some other data may be contained in files that you can read into Singular (see [Section D.4.24.15 \[showNuminvs\]](#), page 1226, [Section D.4.24.16 \[exportNuminvs\]](#), page 1226).

Example:

```
LIB "normaliz.lib";
ring R=0,(x,y,z,w),dp;
intmat V0[2][4]=0,1,2,3, -1,1,2,1;
intersectionValRings(V0);
↪ _[1]=w
↪ _[2]=z
```

```

↳ _[3]=y
↳ _[4]=xw
↳ _[5]=xz
↳ _[6]=xy
↳ _[7]=x2z

```

See also: [Section D.4.24.12 \[diagInvariants\]](#), page 1223; [Section D.4.24.11 \[finiteDiagInvariants\]](#), page 1222; [Section D.4.24.14 \[intersectionValRingIdeals\]](#), page 1225; [Section D.4.24.10 \[torusInvariants\]](#), page 1221.

D.4.24.14 intersectionValRingIdeals

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `intersectionValRingIdeals(intmat V);`
 `intersectionValRingIdeals(intmat V, intvec grading);`

Return: The function returns two ideals, both to be considered as lists of monomials. The first is the system of monomial generators of S , the second the system of generators of M .

The function returns a list consisting of the ideal given by the blocking the computation of Hilbert bases has been activated. However, in this case some numerical invariants are computed, and some other data may be contained in files that you can read into Singular (see [Section D.4.24.15 \[showNuminvs\]](#), page 1226, [Section D.4.24.16 \[exportNuminvs\]](#), page 1226).

Background:

A discrete monomial valuation v on $R = K[X_1, \dots, X_n]$ is determined by the values $v(X_j)$ of the indeterminates. This function computes the subalgebra $S = \{f \in R : v_i(f) \geq 0, i = 1, \dots, r\}$ for several such valuations $v_i, i = 1, \dots, r$. It needs the matrix $V = (v_i(X_j))$ as its input.

This function simultaneously determines the S -submodule $M = \{f \in R : v_i(f) \geq w_i, i = 1, \dots, r\}$ for integers w_1, \dots, w_r . (If $w_i \geq 0$ for all i , M is an ideal of S .) The numbers w_i form the $(n+1)$ th column of the input matrix.

Note: The function also gives an error message if the matrix V has the wrong number of columns.

Example:

```

LIB "normaliz.lib";
ring R=0,(x,y,z,w),dp;
intmat V[2][5]=0,1,2,3,4, -1,1,2,1,3;
intersectionValRingIdeals(V);
↳ [1]:
↳   _[1]=w
↳   _[2]=z
↳   _[3]=y
↳   _[4]=xw
↳   _[5]=xz
↳   _[6]=xy
↳   _[7]=x2z
↳ [2]:
↳   _[1]=w3
↳   _[2]=zw
↳   _[3]=z2

```

```

↳   _[4]=yw2
↳   _[5]=y2w
↳   _[6]=y2z
↳   _[7]=y4
↳   _[8]=xz2
↳   _[9]=xy2z
↳   _[10]=xy4

```

See also: [Section D.4.24.12 \[diagInvariants\]](#), page 1223; [Section D.4.24.11 \[finiteDiagInvariants\]](#), page 1222; [Section D.4.24.13 \[intersectionValRings\]](#), page 1224; [Section D.4.24.10 \[torusInvariants\]](#), page 1221.

D.4.24.15 showNuminvs

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `showNuminvs();`

Purpose: prints the numerical invariants

Example:

```

LIB "normaliz.lib";
ring R=0,(x,y,z,t),dp;
ideal I=x3,x2y,y3;
list l=intclMonIdeal(I);
showNuminvs();
↳ hilbert_basis_elements : 7
↳ number_extreme_rays : 5
↳ dim_max_subspace : 0
↳ embedding_dim : 4
↳ rank : 4
↳ external_index : 1
↳ internal_index : 1
↳ number_support_hyperplanes : 5
↳ size_triangulation : 3
↳ sum_dets : 4
↳ integrally_closed : 0
↳ inhomogeneous : 0
↳ graded : 1
↳ degree_1_elements : 7
↳ grading : 1,1,1,-2
↳ grading_denom : 1
↳ multiplicity : 4
↳ multiplicity_denom : 1
↳ hilbert_series_num : 1,3
↳ hilbert_series_denom : 1,1,1,1
↳ primary : 0
↳ class_group : 1

```

See also: [Section D.4.24.16 \[exportNuminvs\]](#), page 1226.

D.4.24.16 exportNuminvs

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `exportNuminvs();`

Create: Creates top-level variables which contain the numerical invariants. Depending on the options of `normaliz` different invariants are calculated. Use `showNuminvs` ([Section D.4.24.15 \[showNuminvs\]](#), page 1226) to see which invariants are available.

Example:

```
LIB "normaliz.lib";
ring R=0,(x,y,z,t),dp;
ideal I=x3,x2y,y3;
list l=intclMonIdeal(I);
exportNuminvs();
// for example, now the following variables are set:
nmz_hilbert_basis_elements;
⇒ 7
nmz_number_extreme_rays;
⇒ 5
nmz_rank;
⇒ 4
nmz_number_support_hyperplanes;
⇒ 5
nmz_multiplicity;
⇒ 4
nmz_primary;
⇒ 0
```

See also: [Section D.4.24.15 \[showNuminvs\]](#), page 1226.

D.4.24.17 allNmzOptions

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `proc allNmzOptions();`

Purpose: The function prints a list of the Normaliz options that are available in this library: the string naming the option, the default value, and the option sent to Normaliz.

Example:

```
LIB "normaliz.lib";
allNmzOptions();
⇒ supp 0 -s
⇒ triang 0 -T
⇒ volume 0 -v
⇒ hvect 0 -p -- name deprecated, use hvect_deg1
⇒ hvect_deg1 0 -p
⇒ only_hvect 0 -q
⇒ fvect 0 --FVector
⇒ height1 0 -1
⇒ Gorenst 0 -G
⇒ intclosed 0 --IsIntegrallyClosed
⇒ witness 0 --w
⇒ classgroup 0 -C
⇒ normal 0 -n -- name deprecated, use hilbbasvol
⇒ hilbbasvol 0 -n
⇒ normal_l 0 -N -- name deprecated, use hilbbas
⇒ hilbbas 0 -N
⇒ hilb 0 -h -- name deprecated, use hilbbas_hvect
```

```

⇒ hilbbas_hvect 0 -h
⇒ dual 0 -d
⇒ markov 0 --MarkovBasis --BinomialsPacked
⇒ groebner 0 --GroebnerBasis --BinomialsPacked
⇒ lex 0 --Lex
⇒ revlex 0 --RevLex
⇒ lex 0 --Lex
⇒ deglex 0 --DegLex
⇒ genoverori 0 -M --mod
⇒ type 0 --typ
⇒ control 0 -c -- name deprecated, use verbose
⇒ verbose 0 -c
⇒ allf 0 -a
⇒ bigint 0 -B
⇒ threads 8 -x=
⇒ errorcheck 0 -e -- allowed, but ignored by Normaliz
⇒

```

See also: [Section D.4.24.18 \[setNmzOption\]](#), page 1228; [Section D.4.24.20 \[showNmzOptions\]](#), page 1229.

D.4.24.18 setNmzOption

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `setNmzOption(string s, int onoff);`

Purpose: If `onoff=1` the option `s` is activated, and if `onoff=0` it is deactivated. The predefined Normaliz options are accessible via the following names:

```

-s: supp
-t: triang
-v: volume
-p: hvect deprecated, replacement:
-p: hvect_deg1
-q: only_hvect
--FVector: fvect
-l: height1
-G: Gorenst
-w: witness
--IsIntegrallyClosed: intclosed
-C: classgroup
-n: normal deprecated, replacement:
-n: hilbbasvol
-N: normal_l deprecated, replacement:
-N: hilbbas
-h: hilb deprecated, replacement:
-h: hilbbas_hvect
--MarkovBasis: groebner
--GroebnerBasis: markov
--Lex: lex
--RevLex: revlex
--DegLex: deglex
-d: dual

```

```

-M: genoverori
-a: allf
--typ: type
-c: control deprecated, replacement:
-c: verbose
-e: errorcheck allowed, but ignored
-B: bigint Use GMP for arbitrary precision integers
-x=N: threads In this case the int parameter is used to set the number of threads N,
default 8, 0 means no explicit limiting.

```

Further Normaliz options can be added to the nlist by addNmzOption.

Example:

```

LIB "normaliz.lib";
setNmzOption("only_hvect",1);
↪ 1
showNmzOptions();
↪ -f -q -x=8
setNmzOption("only_hvect",0);
↪ 1
showNmzOptions();
↪ -f -x=8

```

See also: [Section D.4.24.19 \[addNmzOption\]](#), page 1229; [Section D.4.24.17 \[allNmzOptions\]](#), page 1227; [Section D.4.24.21 \[resetNmzOptions\]](#), page 1230; [Section D.4.24.20 \[showNmzOptions\]](#), page 1229.

D.4.24.19 addNmzOption

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: addNmzOption(string short_cut, string nmz_option)

Note: This function allows the addition of Normaliz options in addition to the predefined ones. Adding an option does not activate it.
Note: The function prefixes a single letter option by - and multiletter options by --.

Example:

```

LIB "normaliz.lib";
addNmzOption("FL", "FaceLattice");
setNmzOption("FL", 1);
↪ 1
showNmzOptions();
↪ -f -x=8 --FaceLattice
resetNmzOptions();

```

See also: [Section D.4.24.17 \[allNmzOptions\]](#), page 1227; [Section D.4.24.21 \[resetNmzOptions\]](#), page 1230; [Section D.4.24.18 \[setNmzOption\]](#), page 1228; [Section D.4.24.20 \[showNmzOptions\]](#), page 1229.

D.4.24.20 showNmzOptions

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: showNmzOptions();

Return: Returns the string of activated options.

Note: This string is used as parameter when calling Normaliz.

Example:

```
LIB "normaliz.lib";
setNmzOption("hilb",1);
↪ 1
showNmzOptions();
↪ -f -h -x=8
setNmzOption("hilb",0);
↪ 1
showNmzOptions();
↪ -f -x=8
```

See also: [Section D.4.24.18 \[setNmzOption\]](#), page 1228.

D.4.24.21 resetNmzOptions

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `resetNmzOptions();`

Purpose: Resets the options to the default value.

Example:

```
LIB "normaliz.lib";
setNmzOption("only_hvect",1);
↪ 1
showNmzOptions();
↪ -f -q -x=8
resetNmzOptions();
showNmzOptions();
↪ -f -x=8
```

See also: [Section D.4.24.19 \[addNmzOption\]](#), page 1229; [Section D.4.24.17 \[allNmzOptions\]](#), page 1227; [Section D.4.24.18 \[setNmzOption\]](#), page 1228; [Section D.4.24.20 \[showNmzOptions\]](#), page 1229.

D.4.24.22 normaliz

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Return: The function applies Normaliz to the matrix `input_mat` of type `nmz_type`. One can add further pairs "value, type" such as vectors or numerical parameters. See Normaliz manual for possible types and values. The function returns the `intmat` defined by the file `ith` suffix `gen`, provided it has been computed. Otherwise it returns the `input_mat`.

Note: You will find procedures for many applications of Normaliz in this library, so the explicit call of this procedure may not be necessary.

Example:

```
LIB "normaliz.lib";

D.4.24.23 setNmzExecPath

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `setNmzExecPath(string s);` `s` path to the Normaliz executable

Create: `Normaliz::nmz_exec_path` to save the given path `s`

Note: It is not necessary to use this function if the Normaliz executable is in the search path of the system.

Example:

```

LIB "normaliz.lib";
setNmzExecPath("../Normaliz/");

```

See also: [Section D.4.24.18 \[setNmzOption\]](#), page 1228.

D.4.24.24 writeNmzData

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `writeNmzData(intmat M, string nmz_type);`
`writeNmzData(intmat M, string nmz_type, intmat M2, string nmz_type2, ...);`

Create: Creates an input file for Normaliz from the matrix `M`. The second parameter sets the type. How the matrix is interpreted depends on the type. See the Normaliz documentation for more information.

It is also possible to give more than one pair of matrix and type. In

Note: Needs an explicit filename set. The filename is created from the current filename. Note that all high level functions in `normaliz.lib` write and read their data automatically to and from the hard disk so that `writeNmzData` will hardly ever be used explicitly.

Example:

```

LIB "normaliz.lib";
setNmzFilename("VeryInteresting");
intmat sgr[3][3]=1,2,3,4,5,6,7,8,10;
writeNmzData(sgr,"cone_and_lattice");
int dummy=system("sh","cat VeryInteresting.in");
⇒ amb_space auto
⇒ cone_and_lattice
⇒ [
⇒ [1, 2, 3]
⇒ [4, 5, 6]
⇒ [7, 8, 10]
⇒ ]
intmat Inequalities[2][3] = 2,-1,0, // 2x-y >= 0
1, 1,0; // x+y >= 0
intmat Equation[1][3] = 0,1,-1; // y = z
intmat Congruence[1][4] = 1,0,0,3; // x = 0 (3)
writeNmzData(Inequalities,"inequalities",Equation,"equations",Congruence,"congruences");
dummy=system("sh","cat VeryInteresting.in");
⇒ amb_space auto
⇒ inequalities
⇒ [
⇒ [2, -1, 0]
⇒ [1, 1, 0]
⇒ ]
⇒ equations
⇒ [
⇒ [0, 1, -1]
⇒ ]
⇒ congruences
⇒ [
⇒ [1, 0, 0, 3]
⇒ ]

```

See also: [Section D.4.24.25 \[readNmzData\]](#), page 1232; [Section D.4.24.30 \[rmNmzFiles\]](#), page 1234; [Section D.4.24.27 \[setNmzDataPath\]](#), page 1233; [Section D.4.24.26 \[setNmzFilename\]](#), page 1233.

D.4.24.25 readNmzData

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `readNmzData(string suffix);`

Return: Reads an output file of Normaliz containing an integer matrix and returns it as an `intmat`. For example, this function is useful if one wants to inspect the support hyperplanes. The filename is created from the current filename and the suffix given to the function. In addition to file suffixes, also `sup`, `equ` and `cgr` are allowed. They extract the support hyperplanes, equations and congruences, respectively, from the `cst` file.

Note: Needs an explicit filename set by `setNmzFilename`.
 Note that all functions in `normaliz.lib` write and read their data automatically so that `readNmzData` will usually not be used explicitly.
 This function reads only the first matrix in a file! But see `su`, `equ`, `cgr` above.)
 It is the responsibility of the user to make sure that an output file read by this function has been created for the current input file of Normaliz. Files are not automatically

removed before a new computation starts.
 Not every output file can be read by this function.

Example:

```
LIB "normaliz.lib";
setNmzFilename("VeryInteresting");
intmat sgr[3][3]=1,2,3,4,5,6,7,8,9;
intmat sgrnormal=normaliz(sgr,"cone");
readNmzData("sup");
↪ -8,7,0,
↪ 2,-1,0
readNmzData("equ");
↪ 1,-2,1
```

See also: [Section D.4.24.30 \[rmNmzFiles\]](#), page 1234; [Section D.4.24.27 \[setNmzDataPath\]](#), page 1233; [Section D.4.24.26 \[setNmzFilename\]](#), page 1233; [Section D.4.24.24 \[writeNmzData\]](#), page 1231.

D.4.24.26 setNmzFilename

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `setNmzFilename(string s);`

Create: `Normaliz::nmz_filename` to save the given filename `s`

Note: The function sets the filename for the exchange of data. Unless a path is set by `setNmzDataPath`, files will be created in the current directory.
 If a non-empty filename is set, the files created for and by Normaliz are kept. This is mandatory for the data access functions (see [Section D.4.24.24 \[writeNmzData\]](#), page 1231 and [Section D.4.24.25 \[readNmzData\]](#), page 1232).
 Resetting the filename by `setNmzFilename("")` forces the library to return to deletion of temporary files, but the files created while the filename had been set will not be erased.

Example:

```
LIB "normaliz.lib";
setNmzDataPath("examples/");
setNmzFilename("example1");
//now the files for the exchange with Normaliz are examples/example1.SUFFIX
```

See also: [Section D.4.24.25 \[readNmzData\]](#), page 1232; [Section D.4.24.30 \[rmNmzFiles\]](#), page 1234; [Section D.4.24.27 \[setNmzDataPath\]](#), page 1233; [Section D.4.24.24 \[writeNmzData\]](#), page 1231.

D.4.24.27 setNmzDataPath

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `setNmzDataPath(string s);`

Create: `Normaliz::nmz_data_path` to save the given path `s`

Note: The function sets the path for the exchange of data. By default the files will be created in the current directory.
 It seems that Singular cannot use filenames starting with `~` or `$HOME` in its input/output functions.
 You must also avoid path names starting with `/` if you work under Cygwin, since Singular and Normaliz interpret them in different ways.

Example:

```
LIB "normaliz.lib";
setNmzDataPath("examples/");
setNmzFilename("example1");
//now the files for the exchange with Normalize are examples/example1.SUFFIX
```

See also: [Section D.4.24.25 \[readNmzData\]](#), page 1232; [Section D.4.24.30 \[rmNmzFiles\]](#), page 1234; [Section D.4.24.26 \[setNmzFilename\]](#), page 1233; [Section D.4.24.24 \[writeNmzData\]](#), page 1231.

D.4.24.28 writeNmzPaths

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Create: the file `nmz_sing_exec.path` where the path to the Normalize executable is saved
the file `nmz_sing_data.path` where the directory for the exchange of data is saved

Note: Both files are saved in the current directory. If one of the names has not been defined, the corresponding file is created, but contains nothing.

Example:

```
LIB "normaliz.lib";
setNmzExecPath("../Normaliz/");
writeNmzPaths();
int dummy=system("sh","cat nmz_sing_exec.path");
↳ ../Normaliz/
dummy=system("sh","cat nmz_sing_data.path");
↳
```

See also: [Section D.4.24.27 \[setNmzDataPath\]](#), page 1233; [Section D.4.24.23 \[setNmzExecPath\]](#), page 1231; [Section D.4.24.29 \[startNmz\]](#), page 1234.

D.4.24.29 startNmz

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `startNmz();`

Purpose: This function reads the files written by `writeNmzPaths()`, retrieves the path names, and types them on the standard output (as far as they have been set). Thus, once the path names have been stored, a Normalize session can simply be opened by this function.

Example:

```
LIB "normaliz.lib";
writeNmzPaths();
startNmz();
↳ nmz_exec_path not set
↳ nmz_data_path not set
```

See also: [Section D.4.24.27 \[setNmzDataPath\]](#), page 1233; [Section D.4.24.23 \[setNmzExecPath\]](#), page 1231; [Section D.4.24.28 \[writeNmzPaths\]](#), page 1234.

D.4.24.30 rmNmzFiles

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `rmNmzFiles();`

Purpose: This function removes the files created for and by Normaliz, using the last filename specified. It needs an explicit filename set (see [Section D.4.24.26 \[setNmzFilename\]](#), page 1233).

Example:

```
LIB "normaliz.lib";
setNmzFilename("VeryInteresting");
rmNmzFiles();
```

See also: [Section D.4.24.25 \[readNmzData\]](#), page 1232; [Section D.4.24.27 \[setNmzDataPath\]](#), page 1233; [Section D.4.24.26 \[setNmzFilename\]](#), page 1233; [Section D.4.24.24 \[writeNmzData\]](#), page 1231.

D.4.24.31 mons2intmat

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `mons2intmat(ideal I);`

Return: Returns the intmat whose rows represent the leading exponents of the (non-zero) elements of `I`. The length of each row is `nvars(basering)`.

Example:

```
LIB "normaliz.lib";
ring R=0,(x,y,z),dp;
ideal I=x2,y2,x2yz3;
mons2intmat(I);
↪ 2,0,0,
↪ 0,2,0,
↪ 2,1,3
```

See also: [Section D.4.24.32 \[intmat2mons\]](#), page 1235.

D.4.24.32 intmat2mons

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `intmat2mons(intmat M);`

Return: an ideal generated by the monomials which correspond to the exponent vectors given by the rows of `M`

Note: The number of variables in the basering `nvars(basering)` has to be at least the number of columns `ncols(M)`, otherwise the function exits with an error. is thrown (see [Section 5.1.30 \[ERROR\]](#), page 177).

Example:

```
LIB "normaliz.lib";
ring R=0,(x,y,z),dp;
intmat expo_vecs[3][3] =
2,0,0,
0,2,0,
2,1,3;
intmat2mons(expo_vecs);
↪ _[1]=x2
↪ _[2]=y2
↪ _[3]=x2yz3
```

See also: [Section D.4.24.31 \[mons2intmat\]](#), page 1235.

D.4.24.33 binomials2intmat

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `binomials2intmat(ideal I);`

Return: Returns the intmat whose rows represent the exponents of the (non-zero) elements of I which have to be binomials.
The length of each row is `nvars(basering)`.

Example:

```
LIB "normaliz.lib";
ring S = 37,(u,v,w,x,y,z),dp;
ideal I = u2v-xyz, ux2-vyz, uvw-y2z;
binomials2intmat(I);
↪ 2,1,0,-1,-1,-1,
↪ 1,-1,0,2,-1,-1,
↪ 1,1,1,0,-2,-1
```

See also: [Section D.4.24.34 \[intmat2binomials\]](#), page 1236; [Section D.4.24.32 \[intmat2mons\]](#), page 1235; [Section D.4.24.31 \[mons2intmat\]](#), page 1235.

D.4.24.34 intmat2binomials

Procedure from library `normaliz.lib` (see [Section D.4.24 \[normaliz.lib\]](#), page 1213).

Usage: `intmat2binomials(intmat M);`

Return: an ideal generated by the binomials which correspond to the exponent vectors given by the rows of M

Note: The number of variables in the basering `nvars(basering)` has to be at least the number of columns `ncols(M)`, otherwise the function exits with an error is thrown (see [Section 5.1.30 \[ERROR\]](#), page 177). The vector with all entries zero represents 1.

Example:

```
LIB "normaliz.lib";
ring S = 37,(u,v,w,x,y,z),dp;
intmat M[2][6] = 1,0,1,-1,-2,0, -3,4,5,0,0,1;
intmat2binomials(M);
↪ _[1]=-xy2+uw
↪ _[2]=v4w5z-u3
```

See also: [Section D.4.24.33 \[binomials2intmat\]](#), page 1236.

D.4.25 pointid_lib

Library: `pointid.lib`

Purpose: Procedures for computing a factorized lex GB of the vanishing ideal of a set of points via the Axis-of-Evil Theorem (M.G. Marinari, T. Mora)

Author: Stefan Steidel, steidel@mathematik.uni-kl.de

Overview: The algorithm of Cerlienco-Mureddu [Marinari M.G., Mora T., A remark on a remark by Macaulay or Enhancing Lazard Structural Theorem. Bull. of the Iranian Math. Soc., 29 (2003), 103-145] associates to each ordered set of points $A := \{a_1, \dots, a_s\}$ in K^n , $a_i := (a_{i1}, \dots, a_{in})$

- a set of monomials N and
- a bijection $\phi: A \rightarrow N$.

Here $I(A) := \{f \in K[x(1), \dots, x(n)] \mid f(a_i) = 0, \text{ for all } 1 \leq i \leq s\}$ denotes the vanishing ideal of A and $N = \text{Mon}(x(1), \dots, x(n)) \setminus \{LM(f) \mid f \in I(A)\}$ is the set of monomials which do not lie in the leading ideal of $I(A)$ (w.r.t. the lexicographical ordering with $x(n) > \dots > x(1)$). N is also called the set of non-monomials of $I(A)$. NOTE: $\#A = \#N$ and N is a monomial basis of $K[x(1..n)]/I(A)$. In particular, this allows to deduce the set of corner-monomials, i.e. the minimal basis $M := \{m_1, \dots, m_r\}$, $m_1 < \dots < m_r$, of its associated monomial ideal $M(I(A))$, such that

$$M(I(A)) = \{k * m_i \mid k \in \text{Mon}(x(1), \dots, x(n)), m_i \in M\},$$

and (by interpolation) the unique reduced lexicographical Groebner basis $G := \{f_1, \dots, f_r\}$ such that $LM(f_i) = m_i$ for each i , that is, $I(A) = \langle G \rangle$. Moreover, a variation of this algorithm allows to deduce a canonical linear factorization of each element of such a Groebner basis in the sense of the Axis-of-Evil Theorem by M.G. Marinari and T. Mora. More precisely, a combinatorial algorithm and interpolation allow to deduce polynomials

$$y_{\text{mdi}} = x(m) - g_{\text{mdi}}(x(1), \dots, x(m-1)),$$

$$i = 1, \dots, r; m = 1, \dots, n; d \text{ in a finite index-set } F, \text{ satisfying}$$

$$f_i = (\text{product of } y_{\text{mdi}}) \text{ modulo } (f_1, \dots, f_{i-1})$$

where the product runs over all $m = 1, \dots, n$; and all d in F .

Procedures:

D.4.25.1 nonMonomials

Procedure from library `pointid.lib` (see [Section D.4.25 \[pointid.lib\]](#), page 1236).

- Usage:** `nonMonomials(id)`; $id = \langle \text{list of vectors} \rangle$ or $\langle \text{list of lists} \rangle$ or $\langle \text{module} \rangle$ or $\langle \text{matrix} \rangle$.
 Let $A = \{a_1, \dots, a_s\}$ be a set of points in K^n , $a_i := (a_{i1}, \dots, a_{in})$, then A can be given as
- a list of vectors (the a_i are vectors) or
 - a list of lists (the a_i are lists of numbers) or
 - a module s.t. the a_i are generators or
 - a matrix s.t. the a_i are columns
- Assume:** basering must have ordering ip , i.e., be of the form $0, x(1..n), ip$; (the first entry of a point belongs to the lex-smallest variable, etc.)
- Return:** ideal, the non-monomials of the vanishing ideal $I(A)$ of A
- Purpose:** compute the set of non-monomials $\text{Mon}(x(1), \dots, x(n)) \setminus \{LM(f) \mid f \in I(A)\}$ of the vanishing ideal $I(A)$ of the given set of points A in K^n , where $K[x(1), \dots, x(n)]$ is equipped with the lexicographical ordering induced by $x(1) < \dots < x(n)$ by using the algorithm of Cerlienco-Mureddu

Example:

```
LIB "pointid.lib";
ring R1 = 0, x(1..3), ip;
vector a1 = [4, 0, 0];
vector a2 = [2, 1, 4];
vector a3 = [2, 4, 0];
vector a4 = [3, 0, 1];
vector a5 = [2, 1, 3];
```

```

vector a6 = [1,3,4];
vector a7 = [2,4,3];
vector a8 = [2,4,2];
vector a9 = [1,0,2];
list A = a1,a2,a3,a4,a5,a6,a7,a8,a9;
nonMonomials(A);
↳ _[1]=1
↳ _[2]=x(1)
↳ _[3]=x(2)
↳ _[4]=x(1)^2
↳ _[5]=x(3)
↳ _[6]=x(1)^3
↳ _[7]=x(2)*x(3)
↳ _[8]=x(3)^2
↳ _[9]=x(1)*x(2)
matrix MAT[9][3] = 4,0,0,2,1,4,2,4,0,3,0,1,2,1,3,1,3,4,2,4,3,2,4,2,1,0,2;
MAT = transpose(MAT);
print(MAT);
↳ 4,2,2,3,2,1,2,2,1,
↳ 0,1,4,0,1,3,4,4,0,
↳ 0,4,0,1,3,4,3,2,2
nonMonomials(MAT);

↳ _[5]=x(3)
↳ _[6]=x(1)^3
↳ _[7]=x(2)*x(3)
↳ _[8]=x(3)^2
↳ _[9]=x(1)*x(2)
module MOD = gen(3),gen(2)-2*gen(3),2*gen(1)+2*gen(3),2*gen(2)-2*gen(3),gen(1)+3*gen(2);
print(MOD);
↳ 0,0, 2,0, 1,1,1,
↳ 0,1, 0,2, 0,1,1,
↳ 1,-2,2,-2,3,3,1
nonMonomials(MOD);
↳ _[1]=1
↳ _[2]=x(2)
↳ _[3]=x(1)
↳ _[4]=x(2)^2
↳ _[5]=x(1)^2
↳ _[6]=x(1)*x(2)
↳ _[7]=x(3)
ring R2 = 0,x(1..2),ip;
list l1 = 0,0;
list l2 = 0,1;
list l3 = 2,0;
list l4 = 0,2;
list l5 = 1,0;
list l6 = 1,1;
list L = l1,l2,l3,l4,l5,l6;
nonMonomials(L);

```

```

↳ _[1]=1
↳ _[2]=x(2)
↳ _[3]=x(1)
↳ _[4]=x(2)^2
↳ _[5]=x(1)^2
↳ _[6]=x(1)*x(2)

```

D.4.25.2 cornerMonomials

Procedure from library `pointid.lib` (see [Section D.4.25 \[pointid.lib\]](#), page 1236).

Usage: `cornerMonomials(N)`; N ideal

Assume: N is given by monomials satisfying the condition that if a monomial is in N then any of its factors is in N (N is then called an order ideal)

Return: ideal, the corner-monomials of the order ideal N
The corner-monomials are the leading monomials of an ideal I s.t. N is a basis of basing/I .

Note: In our applications, I is the vanishing ideal of a finite set of points.

Example:

```

LIB "pointid.lib";
ring R = 0,x(1..3),ip;
poly n1 = 1;
poly n2 = x(1);
poly n3 = x(2);
poly n4 = x(1)^2;
poly n5 = x(3);
poly n6 = x(1)^3;
poly n7 = x(2)*x(3);
poly n8 = x(3)^2;
poly n9 = x(1)*x(2);
ideal N = n1,n2,n3,n4,n5,n6,n7,n8,n9;
cornerMonomials(N);
↳ _[1]=x(1)^4
↳ _[2]=x(1)^2*x(2)
↳ _[3]=x(2)^2
↳ _[4]=x(1)*x(3)
↳ _[5]=x(2)*x(3)^2
↳ _[6]=x(3)^3

```

D.4.25.3 facGBIdeal

Procedure from library `pointid.lib` (see [Section D.4.25 \[pointid.lib\]](#), page 1236).

Usage: `facGBIdeal(id)`; $id = \langle \text{list of vectors} \rangle$ or $\langle \text{list of lists} \rangle$ or $\langle \text{module} \rangle$ or $\langle \text{matrix} \rangle$.
Let $A = \{a_1, \dots, a_s\}$ be a set of points in K^n , $a_i := (a_{i1}, \dots, a_{in})$, then A can be given as

- a list of vectors (the a_i are vectors) or
- a list of lists (the a_i are lists of numbers) or
- a module s.t. the a_i are generators or
- a matrix s.t. the a_i are columns

Assume: `basing` must have ordering `ip`, i.e., be of the form `0,x(1..n),ip`; (the first entry of a point belongs to the lex-smallest variable, etc.)

Return: a list where the first entry contains the Groebner basis G of $I(A)$ and the second entry contains the linear factors of each element of G

Note: combinatorial algorithm due to the Axis-of-Evil Theorem of M.G. Marinari, T. Mora

Example:

```
LIB "pointid.lib";
ring R = 0,x(1..3),ip;
vector a1 = [4,0,0];
vector a2 = [2,1,4];
vector a3 = [2,4,0];
vector a4 = [3,0,1];
vector a5 = [2,1,3];
vector a6 = [1,3,4];
vector a7 = [2,4,3];
vector a8 = [2,4,2];
vector a9 = [1,0,2];
list A = a1,a2,a3,a4,a5,a6,a7,a8,a9;
facGBIdeal(A);
⇒ [1]:
⇒ _[1]=x(1)^4-10*x(1)^3+35*x(1)^2-50*x(1)+24
⇒ _[2]=x(1)^2*x(2)-3*x(1)*x(2)+2*x(2)
⇒ _[3]=x(2)^2-1/2*x(1)^2*x(2)-1/2*x(1)*x(2)-2*x(2)+2*x(1)^3-16*x(1)^2+38\

D.4.26 primdec_lib

Library: primdec.lib

Purpose: Primary Decomposition and Radical of Ideals

Authors: Gerhard Pfister, pfister@mathematik.uni-kl.de (GTZ)
 Wolfram Decker, decker@math.uni-sb.de (SY)
 Hans Schoenemann, hannes@mathematik.uni-kl.de (SY)
 Santiago Laplagne, slaplagn@dm.uba.ar (GTZ)

Overview: Algorithms for primary decomposition based on the ideas of Gianni, Trager and Zacharias (implementation by Gerhard Pfister), respectively based on the ideas of Shimoyama and Yokoyama (implementation by Wolfram Decker and Hans Schoenemann). The procedures are implemented to be used in characteristic 0. They also work in positive characteristic $>> 0$. In small characteristic and for algebraic extensions, primdecGTZ may not terminate. Algorithms for the computation of the radical based on the ideas of Krick, Logar, Laplagne and Kemper (implementation by Gerhard Pfister and Santiago Laplagne). They work in any characteristic. Baserings must have a global ordering and no quotient ideal. Exceptions: primdecGTZ, absPrimdecGTZ, minAssGTZ, primdecSY, minAssChar, radical accept non-global ordering.

Procedures: See also: [Section D.4.27 \[primdecint_lib\]](#), page 1256.

D.4.26.1 Ann

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec_lib\]](#), page 1243).

Usage: Ann(M); M module

Return: ideal, the annihilator of `coker(M)`

Note: The output is the ideal of all elements a of the basering R such that $a * R^m$ is contained in M (m =number of rows of M).

Example:

```

LIB "primdec.lib";
ring r = 0,(x,y,z),lp;
module M = x2-y2,z3;
Ann(M);
  ↳ _[1]=z3
  ↳ _[2]=x2-y2
M = [1,x2],[y,x];
Ann(M);
  ↳ _[1]=x2y-x
qring Q=std(xy-1);
module M=imap(r,M);
Ann(M);
  ↳ _[1]=0

```

D.4.26.2 primdecGTZ

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\]](#), page 1243).

Usage: `primdecGTZ(I);` I ideal

Return: a list `pr` of primary ideals and their associated primes for a proper ideal `I`, otherwise
`pr = list(list(ideal(1), ideal(1))`
 `pr[i][1]` the i-th primary component,
 `pr[i][2]` the i-th prime component.

Note:

- Algorithm of Gianni/Trager/Zacharias.
- Designed for characteristic 0, works also in char $k > 0$, if it terminates (may result in an infinite loop in small characteristic!) - For local orderings, the result is considered in the localization of the polynomial ring, not in the power series ring
- For local and mixed orderings, the decomposition in the corresponding global ring is returned if the string 'global' is specified as second argument

Example:

```

LIB "primdec.lib";
ring r = 0,(x,y,z),lp;
poly p = z2+1;
poly q = z3+2;
ideal i = p*q^2,y-z2;
list pr = primdecGTZ(i);
pr;
  ↳ [1]:
  ↳   [1]:
  ↳     _[1]=z2+1
  ↳     _[2]=y-z2
  ↳   [2]:
  ↳     _[1]=z2+1
  ↳     _[2]=y-z2
  ↳ [2]:
  ↳   [1]:
  ↳     _[1]=z6+4z3+4
  ↳     _[2]=y-z2
  ↳   [2]:
  ↳     _[1]=z3+2
  ↳     _[2]=y-z2

```

D.4.26.3 primdecGTZE

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\], page 1243](#)).

Usage: `primdecGTZE(I); i ideal`

Return: a list `pr` of primary ideals and their associated primes for a proper ideal, and an empty list for the unit ideal.

`pr[i][1]` the i -th primary component,
`pr[i][2]` the i -th prime component.

Note:

- Algorithm of Gianni/Trager/Zacharias.
- Designed for characteristic 0, works also in char $k > 0$, if it terminates (may result in an infinite loop in small characteristic!) - For local orderings, the result is considered in the localization of the polynomial ring, not in the power series ring
- For local and mixed orderings, the decomposition in the corresponding global ring is returned if the string 'global' is specified as second argument

Example:

```
LIB "primdec.lib";
ring r = 0,(x,y,z),lp;
poly p = z2+1;
poly q = z3+2;
ideal I = p*q^2,y-z2;
list pr = primdecGTZE(I);
pr;
⇒ [1]:
⇒ [1]:
⇒ [1]=z2+1
⇒ [2]=y-z2
⇒ [2]:
⇒ [1]=z2+1
⇒ [2]=y-z2
⇒ [2]:
⇒ [1]:
⇒ [1]=z6+4z3+4
⇒ [2]=y-z2
⇒ [2]:
⇒ [1]=z3+2
⇒ [2]=y-z2
ideal J = 1;
list premt = primdecGTZE(J);
premt;
⇒ empty list
```

D.4.26.4 primdecSY

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\], page 1243](#)).

Usage: `primdecSY(I, c); I ideal, c int (optional)`

Return: a list `pr` of primary ideals and their associated primes for proper ideal `I`, otherwise `pr[1]` is `list(ideal(1),ideal(1))`

`pr[i][1]` the i -th primary component,
`pr[i][2]` the i -th prime component.

Note: Algorithm of Shimoyama/Yokoyama.

if $c=0$, the given ordering of the variables is used,
 if $c=1$, `minAssChar` tries to use an optimal ordering (default),
 if $c=2$, `minAssGTZ` is used,
 if $c=3$, `minAssGTZ` and `facstd` are used.

For local orderings, the result is considered in the localization of the polynomial ring, not in the power series ring.

For local and mixed orderings, the decomposition in the corresponding global ring is returned if the string 'global' is specified as third argument

Example:

```
LIB "primdec.lib";
ring r = 0,(x,y,z),lp;
poly p = z2+1;
poly q = z3+2;
ideal i = p*q^2,y-z2;
list pr = primdecSY(i);
pr;
⇒ [1]:
⇒ [1]:
⇒ [1]=z6+4z3+4
⇒ [2]=y-z2
⇒ [2]:
⇒ [1]=z3+2
⇒ [2]=y-z2
⇒ [2]:
⇒ [1]:
⇒ [1]=z2+1
⇒ [2]=y-z2
⇒ [2]:
⇒ [1]=z2+1
⇒ [2]=y+1
```

D.4.26.5 primdecSYE

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\]](#), page 1243).

Usage: `primdecSYE(I, c);` I ideal, c int (optional)

Return: a list `pr` of primary ideals and their associated primes:

`pr[i][1]` the i-th primary component,
`pr[i][2]` the i-th prime component.

If I is the unit ideal returns an empty list.

Note: Algorithm of Shimoyama/Yokoyama.

if $c=0$, the given ordering of the variables is used,
 if $c=1$, `minAssChar` tries to use an optimal ordering (default),
 if $c=2$, `minAssGTZ` is used,
 if $c=3$, `minAssGTZ` and `facstd` are used.

For local orderings, the result is considered in the localization of the polynomial ring, not in the power series ring.

For local and mixed orderings, the decomposition in the corresponding global ring is returned if the string 'global' is specified as third argument

Example:

```

LIB "primdec.lib";
ring r = 0,(x,y,z),lp;
poly p = z2+1;
poly q = z3+2;
ideal I = p*q^2,y-z2;
list pr = primdecSYE(I);
pr;
⇒ [1]:
⇒ [1]:
⇒ _[1]=z6+4z3+4
⇒ _[2]=y-z2
⇒ [2]:
⇒ _[1]=z3+2
⇒ _[2]=y-z2
⇒ [2]:
⇒ [1]:
⇒ _[1]=z2+1
⇒ _[2]=y-z2
⇒ [2]:
⇒ _[1]=z2+1
⇒ _[2]=y+1
ideal J = x;
list prUnit = primdecSYE(J);
prUnit;
⇒ [1]:
⇒ [1]:
⇒ _[1]=x
⇒ [2]:
⇒ _[1]=x

```

D.4.26.6 minAssGTZ

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\]](#), page 1243).

Usage: `minAssGTZ(I[, l]);` I ideal, l list (optional)
Optional parameters in list l (can be entered in any order):
0, "facstd" -> uses facstd to first decompose the ideal (default)
1, "noFacstd" -> does not use facstd
"GTZ" -> the original algorithm by Gianni, Trager and Zacharias is used
"SL" -> GTZ algorithm with modifications by Laplagne is used (default)

Return: a list, the minimal associated prime ideals of proper ideal I, otherwise ideal(1)

Note:

- Designed for characteristic 0, works also in char $k > 0$ based on an algorithm of Yokoyama
- For local orderings, the result is considered in the localization of the polynomial ring, not in the power series ring
- For local and mixed orderings, the decomposition in the corresponding global ring is returned if the string 'global' is specified as second argument

Example:

```

LIB "primdec.lib";
ring r = 0,(x,y,z),dp;

```

```

poly p = z2+1;
poly q = z3+2;
ideal i = p*q^2,y-z2;
list pr = minAssGTZ(i);
pr;
⇒ [1]:
⇒   _[1]=z3+2
⇒   _[2]=-z2+y
⇒ [2]:
⇒   _[1]=z2+1
⇒   _[2]=-z2+y

```

D.4.26.7 minAssGTZE

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\]](#), page 1243).

Usage: `minAssGTZE(I, l);` I ideal, l list (optional)
Optional parameters in list l (can be entered in any order):
0, "facstd" -> uses facstd to first decompose the ideal (default)
1, "noFacstd" -> does not use facstd
"GTZ" -> the original algorithm by Gianni, Trager and Zacharias is used
"SL" -> GTZ algorithm with modifications by Laplagne is used (default)

Return: a list, the minimal associated prime ideals of I.

Note:

- Designed for characteristic 0, works also in char $k > 0$ based on an algorithm of Yokoyama
- For local orderings, the result is considered in the localization of the polynomial ring, not in the power series ring
- For local and mixed orderings, the decomposition in the corresponding global ring is returned if the string 'global' is specified as second argument

Example:

```

LIB "primdec.lib";
ring r = 0,(x,y,z),dp;
poly p = z2+1;
poly q = z3+2;
ideal I = p*q^2,y-z2;
list pr = minAssGTZE(I);
pr;
⇒ [1]:
⇒   _[1]=z3+2
⇒   _[2]=-z2+y
⇒ [2]:
⇒   _[1]=z2+1
⇒   _[2]=-z2+y
ideal J = 1;
list preempty = minAssGTZE(J);
preempty;
⇒ empty list

```

D.4.26.8 minAssChar

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\]](#), page 1243).

- Usage:** `minAssChar(I[,c]);` i ideal, c int (optional).
- Return:** list, the minimal associated prime ideals of I. If I is the unit ideal returns `list(ideal(1))`
- Note:** If `c=0`, the given ordering of the variables is used.
 Otherwise, the system tries to find an optimal ordering, which in some cases may considerably speed up the algorithm.
 For local orderings, the result is considered in the localization of the polynomial ring, not in the power series ring
 For local and mixed orderings, the decomposition in the corresponding global ring is returned if the string 'global' is specified as third argument

Example:

```
LIB "primdec.lib";
ring r = 0, (x,y,z), dp;
poly p = z2+1;
poly q = z3+2;
ideal i = p*q^2,y-z2;
list pr = minAssChar(i);
pr;
⇒ [1]:
⇒ _[1]=y+1
⇒ _[2]=z2+1
⇒ [2]:
⇒ _[1]=z2-y
⇒ _[2]=yz+2
⇒ _[3]=y2+2z
```

D.4.26.9 minAssCharE

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\]](#), page 1243).

- Usage:** `minAssCharE(I[,c]);` i ideal, c int (optional).
- Return:** list, the minimal associated prime ideals of I. If I is the unit ideal returns an empty list.
- Note:** If `c=0`, the given ordering of the variables is used.
 Otherwise, the system tries to find an optimal ordering, which in some cases may considerably speed up the algorithm.
 For local orderings, the result is considered in the localization of the polynomial ring, not in the power series ring
 For local and mixed orderings, the decomposition in the corresponding global ring is returned if the string 'global' is specified as third argument

Example:

```
LIB "primdec.lib";
ring r = 0, (x,y,z), dp;
poly p = z2+1;
poly q = z3+2;
ideal I = p*q^2,y-z2;
list pr = minAssCharE(I);
pr;
⇒ [1]:
```

```

↪    _[1]=y+1
↪    _[2]=z2+1
↪ [2]:
↪    _[1]=z2-y
↪    _[2]=yz+2
↪    _[3]=y2+2z
ideal J = 5;
list preempty = minAssCharE(J);
preempty;
↪ empty list

```

D.4.26.10 testPrimary

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\], page 1243](#)).

Usage: `testPrimary(pr,k)`; `pr` a list, `k` an ideal.

Assume: `pr` is the result of `primdecGTZ(k)` or `primdecSY(k)`.

Return: `int`, 1 if the intersection of the ideals in `pr` is `k`, 0 if not

Example:

```

LIB "primdec.lib";
ring r = 32003,(x,y,z),dp;
poly p = z2+1;
poly q = z4+2;
ideal i = p^2*q^3,(y-z3)^3,(x-yz+z4)^4;
list pr = primdecGTZ(i);
testPrimary(pr,i);
↪ 1

```

D.4.26.11 testPrimaryE

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\], page 1243](#)).

Usage: `testPrimaryE(pr,k)`; `pr` a list, `k` an ideal.

Assume: `pr` is the result of a primary decomposition and may be empty (for the unit ideal)

Return: `int`, 1 if the intersection of the ideals in `pr` is `k`, 0 if not

Example:

```

LIB "primdec.lib";
ring r = 32003,(x,y,z),dp;
poly p = z2+1;
poly q = z4+2;
ideal i = p^2*q^3,(y-z3)^3,(x-yz+z4)^4;
list pr = primdecGTZ(i);
testPrimaryE(pr,i);
↪ 1

```

D.4.26.12 radical

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\], page 1243](#)).

Usage: `radical(I[, l]);` I ideal, l list (optional)
 Optional parameters in list l (can be entered in any order):
 0, "fullRad" -> full radical is computed (default)
 1, "equiRad" -> equiRadical is computed
 "KL" -> Krick/Logar algorithm is used
 "SL" -> modifications by Laplagne are used (default)
 "facstd" -> uses facstd to first decompose the ideal (default for non homogeneous
 ideals)
 "noFacstd" -> does not use facstd (default for homogeneous ideals)

Return: ideal, the radical of I (or the equiradical if required in the input parameters)

Note: A combination of the algorithms of Krick/Logar (with modifications by Laplagne) and
 Kemper is used. Works also in positive characteristic (Kempers algorithm).

Example:

```
LIB "primdec.lib";
ring r = 0, (x,y,z), dp;
poly p = z2+1;
poly q = z3+2;
ideal i = p*q^2, y-z2;
ideal pr = radical(i);
pr;
↪ pr[1]=z2-y
↪ pr[2]=y2z+z3+2z2+2
```

D.4.26.13 radicalEHV

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\]](#), page 1243).

Usage: `radicalEHV(i);` i ideal.

Return: ideal, the radical of i.

Note: Uses the algorithm of Eisenbud/Huneke/Vasconcelos, which reduces the computation
 to the complete intersection case, by taking, in the general case, a generic linear com-
 bination of the input.
 Works only in characteristic 0 or p large.

Example:

```
LIB "primdec.lib";
ring r = 0, (x,y,z), dp;
poly p = z2+1;
poly q = z3+2;
ideal i = p*q^2, y-z2;
ideal pr= radicalEHV(i);
pr;
↪ pr[1]=z2-y
↪ pr[2]=y2z+yz+2y+2
↪ pr[3]=y3+y2+2yz+2z
```

D.4.26.14 equiRadical

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\]](#), page 1243).

Usage: `equiRadical(I);` I ideal

Return: ideal, intersection of associated primes of I of maximal dimension.

Note: A combination of the algorithms of Krick/Logar (with modifications by Laplagne) and Kemper is used. Works also in positive characteristic (Kempers algorithm).

Example:

```
LIB "primdec.lib";
ring r = 0, (x,y,z), dp;
poly p = z2+1;
poly q = z3+2;
ideal i = p*q^2, y-z2;
ideal pr = equiRadical(i);
pr;
↪ pr[1]=z2-y
↪ pr[2]=y2z+z3+2z2+2
```

D.4.26.15 prepareAss

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\]](#), page 1243).

Usage: `prepareAss(I)`; I ideal

Return: list of radicals of the equidimensional components of I

Note: Uses algorithm of Eisenbud/Huneke/Vasconcelos.

Example:

```
LIB "primdec.lib";
ring r = 0, (x,y,z), dp;
poly p = z2+1;
poly q = z3+2;
ideal i = p*q^2, y-z2;
list pr = prepareAss(i);
pr;
↪ [1]:
↪ _[1]=z2-y
↪ _[2]=y2z+z3+2z2+2
```

D.4.26.16 equidim

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\]](#), page 1243).

Usage: `equidim(I)` or `equidim(I,1)` ; I ideal

Return: list of equidimensional ideals $a[1], \dots, a[s]$ with:
 - $a[s]$ the equidimensional locus of I , i.e. the intersection of the primary ideals of dimension of I , except I is unit ideal. - $a[1], \dots, a[s-1]$ the lower dimensional equidimensional loci. If I is the unit ideal, a list containing the unit ideal as $a[1]$ is returned.

Note: An embedded component q (primary ideal) of I can be replaced in the decomposition by a primary ideal q_1 with the same radical as q .
`equidim(I,1)` uses the algorithm of Eisenbud/Huneke/Vasconcelos.

Example:

```
LIB "primdec.lib";
ring r = 32003, (x,y,z), dp;
ideal i = intersect(ideal(z), ideal(x,y), ideal(x2,z2), ideal(x5,y5,z5));
```

```

equidim(i);
↳ [1]:
↳   _[1]=z4
↳   _[2]=y5
↳   _[3]=x5
↳   _[4]=x3z3
↳   _[5]=x4y4
↳ [2]:
↳   _[1]=yz
↳   _[2]=xz
↳   _[3]=x2
↳ [3]:
↳   _[1]=z

```

D.4.26.17 equidimMax

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\], page 1243](#)).

Usage: `equidimMax(i); i ideal`

Return: ideal of equidimensional locus (of maximal dimension) of `i`.

Example:

```

LIB "primdec.lib";
ring r = 32003, (x,y,z), dp;
ideal i = intersect(ideal(z), ideal(x,y), ideal(x2,z2), ideal(x5,y5,z5));
equidimMax(i);
↳ _[1]=z

```

D.4.26.18 equidimMaxEHV

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\], page 1243](#)).

Usage: `equidimMaxEHV(I); I ideal`

Return: ideal, the equidimensional component (of maximal dimension) of `I`.

Note: Uses algorithm of Eisenbud, Huneke and Vasconcelos.

Example:

```

LIB "primdec.lib";
ring r = 0, (x,y,z), dp;
ideal i=intersect(ideal(z), ideal(x,y), ideal(x2,z2), ideal(x5,y5,z5));
equidimMaxEHV(i);
↳ _[1]=z

```

D.4.26.19 zerodec

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\], page 1243](#)).

Usage: `zerodec(I); I ideal`

Assume: `I` is zero-dimensional, the characteristic of the ground field is 0

Return: list of primary ideals, the zero-dimensional decomposition of `I`

Note: The algorithm (of Monico), works well only for a small total number of solutions ($\text{vdim}(\text{std}(I))$ should be < 100) and without parameters. In practice, it works also in large characteristic $p > 0$ but may fail for small p .
If $\text{printlevel} > 0$ (default = 0) additional information is displayed.

Example:

```
LIB "primdec.lib";
ring r = 0,(x,y),dp;
ideal i = x2-2,y2-2;
list pr = zerodec(i);
pr;
⇒ [1]:
⇒   _[1]=y2-2
⇒   _[2]=xy-2
⇒   _[3]=x2-2
⇒ [2]:
⇒   _[1]=y2-2
⇒   _[2]=xy+2
⇒   _[3]=x2-2
```

D.4.26.20 absPrimdecGTZ

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\]](#), page 1243).

Usage: `absPrimdecGTZ(I); I ideal`

Assume: Ground field has characteristic 0.

Return: a ring containing two lists: `absolute_primes`, the absolute prime components of I , and `primary_decomp`, the output of `primdecGTZ(I)`. The list `absolute_primes` has to be interpreted as follows: each entry describes a class of conjugated absolute primes,
`absolute_primes[i][1]` the absolute prime component,
`absolute_primes[i][2]` the number of conjugates.

The first entry of `absolute_primes[i][1]` is the minimal polynomial of a minimal finite field extension over which the absolute prime component is defined.

For local orderings, the result is considered in the localization of the polynomial ring, not in the power series ring. For local and mixed orderings, the decomposition in the corresponding global ring is returned if the string 'global' is specified as second argument

Note: Algorithm of Gianni/Trager/Zacharias combined with the `absFactorize` command.

Example:

```
LIB "primdec.lib";
ring r = 0,(x,y,z),lp;
poly p = z2+1;
poly q = z3+2;
ideal i = p*q^2,y-z2;
def S = absPrimdecGTZ(i);
⇒
⇒ // 'absPrimdecGTZ' created a ring, in which two lists absolute_primes (th\
e
⇒ // absolute prime components) and primary_decomp (the primary and prime
⇒ // components over the current basering) are stored.
⇒ // To access the list of absolute prime components, type (if the name S w\
```

```

as
⇒ // assigned to the return value):
⇒      setring S; absolute_primes;
setring S;
absolute_primes;
⇒ [1]:
⇒      [1]:
⇒      _[1]=a2+1
⇒      _[2]=z-a
⇒      _[3]=y+1
⇒      [2]:
⇒      2
⇒ [2]:
⇒      [1]:
⇒      _[1]=a3+2
⇒      _[2]=z-a
⇒      _[3]=y-a2
⇒      [2]:
⇒      3

```

See also: [Section D.4.1.1 \[absFactorize\]](#), page 1003; [Section D.4.26.2 \[primdecGTZ\]](#), page 1244.

D.4.26.21 absPrimdecGTZE

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\]](#), page 1243).

Usage: `absPrimdecGTZE(I); I ideal`

Assume: Ground field has characteristic 0.

Return: a ring containing two lists: `absolute_primes`, the absolute prime components of `I`, and `primary_decomp`, the output of `primdecGTZ(I)`. Will fail for unit ideal. The list `absolute_primes` has to be interpreted as follows: each entry describes a class of conjugated absolute primes,

`absolute_primes[i][1]` the absolute prime component,
`absolute_primes[i][2]` the number of conjugates.

The first entry of `absolute_primes[i][1]` is the minimal polynomial of a minimal finite field extension over which the absolute prime component is defined.

For local orderings, the result is considered in the localization of the polynomial ring, not in the power series ring. For local and mixed orderings, the decomposition in the corresponding global ring is returned if the string 'global' is specified as second argument

Note: Algorithm of Gianni/Trager/Zacharias combined with the `absFactorize` command.

Example:

```

LIB "primdec.lib";
ring r = 0,(x,y,z),lp;
poly p = z2+1;
poly q = z3+2;
ideal I = p*q^2,y-z2;
def S = absPrimdecGTZE(I);
⇒
⇒ // 'absPrimdecGTZ' created a ring, in which two lists absolute_primes (th\
e

```

```

⇒ // absolute prime components) and primary_decomp (the primary and prime
⇒ // components over the current basering) are stored.
⇒ // To access the list of absolute prime components, type (if the name S w\
    as
⇒ // assigned to the return value):
⇒      setring S; absolute_primes;
setring S;
absolute_primes;
⇒ [1]:
⇒      [1]:
⇒          _[1]=a2+1
⇒          _[2]=z-a
⇒          _[3]=y+1
⇒      [2]:
⇒          2
⇒ [2]:
⇒      [1]:
⇒          _[1]=a3+2
⇒          _[2]=z-a
⇒          _[3]=y-a2
⇒      [2]:
⇒          3

```

See also: [Section D.4.1.1 \[absFactorize\], page 1003](#); [Section D.4.26.2 \[primdecGTZ\], page 1244](#).

D.4.26.22 sep

Procedure from library `primdec.lib` (see [Section D.4.26 \[primdec.lib\], page 1243](#)).

Example:

```

LIB "primdec.lib";
ring R=(5,t,s),(x,y,z),dp;
poly f=(x^25-t*x^5+t)*(x^3+s);
sep(f,1);
⇒ [1]:
⇒      x8+(s5)*x5+(-t)*x4+(t)*x3+(-ts5)*x+(ts5)
⇒ [2]:
⇒      1

```

D.4.27 primdecint.lib

Library: `primdecint.lib`

Purpose: primary decomposition of an ideal in the polynomial ring over the integers

Authors: G. Pfister pfister@mathematik.uni-kl.de
A. Sadiq afshanatiq@gmail.com
S. Steidel steidel@mathematik.uni-kl.de

Overview: A library for computing the primary decomposition of an ideal in the polynomial ring over the integers, $\mathbb{Z}[x_1, \dots, x_n]$.

The first procedure 'primdecZ' can be used in parallel. The coefficients must always be \mathbb{Z} .

Reference: Pfister, Sadiq, Steidel, "An Algorithm for primary decomposition in polynomial rings over the integers", arXiv:1008.2074

Procedures: See also: [Section D.4.26 \[primdec_lib\], page 1243](#).

D.4.27.1 primdecZ

Procedure from library `primdecint.lib` (see [Section D.4.27 \[primdecint_lib\], page 1256](#)).

Usage: `primdecZ(I[, n]);` I ideal, n integer (number of processors)

Note: If `size(#)` > 0, then `#[1]` is the number of available processors for the computation.
The coefficients must be ZZ.

Return: a list pr of primary ideals and their associated primes:

`pr[i][1]` the i-th primary component,
`pr[i][2]` the i-th prime component.

Example:

```
LIB "primdecint.lib";
ring R=integer,(a,b,c,d),dp;
ideal I1=9,a,b;
ideal I2=3,c;
ideal I3=11,2a,7b;
ideal I4=13a2,17b4;
ideal I5=9c5,6d5;
ideal I6=17,a15,b15,c15,d15;
ideal I=intersectZ(I1,I2);
I=intersectZ(I,I3);
I=intersectZ(I,I4);
I=intersectZ(I,I5);
I=intersectZ(I,I6);
primdecZ(I);

⇒      [2]:
⇒      _[1]=3
⇒      _[2]=a

```

D.4.27.2 primdecZM

Procedure from library `primdecint.lib` (see [Section D.4.27 \[primdecint.lib\]](#), page 1256).

Usage: `primdecZM(N)`; N module
 The coefficients must be ZZ.

Return: a list `pr` of primary modules and their associated primes:
 `pr[i][1]` the i-th primary component,
 `pr[i][2]` the i-th prime component.

Example:

```

LIB "primdecint.lib";
ring R=integer,(x,y),(c,lp);
module N=[0,0,xy2-x2-xy],[0,y,x],[0,x,2xy-x],[x,0,-xy],[0,0,18x];
primdecZM(N);
⇒ [1]:
⇒      [1]:
⇒      _[1]=[0,0,x]
⇒      _[2]=[0,1]
⇒      _[3]=[x]
⇒      [2]:
⇒      _[1]=x
⇒ [2]:
⇒      [1]:
⇒      _[1]=[0,0,y3]
⇒      _[2]=[0,0,18x]
⇒      _[3]=[0,0,xy2]
⇒      _[4]=[0,0,x2+xy]
⇒      _[5]=[0,y,x]
⇒      _[6]=[0,x,2xy-x]
⇒      _[7]=[y3]
⇒      _[8]=[x,0,-xy]
⇒      [2]:
⇒      _[1]=y
⇒      _[2]=x

```

D.4.27.3 minAssZ

Procedure from library `primdecint.lib` (see [Section D.4.27 \[primdecint.lib\]](#), page 1256).

Usage: `minAssZ(I);` I ideal
 The coefficients must be $\mathbb{Z}\mathbb{Z}$.

Return: a list `pr` of associated primes:

Example:

```
LIB "primdecint.lib";
ring R=integer,(a,b,c,d),dp;
ideal I1=9,a,b;
ideal I2=3,c;
ideal I3=11,2a,7b;
ideal I4=13a2,17b4;
ideal I5=9c5,6d5;
ideal I6=17,a15,b15,c15,d15;
ideal I=intersectZ(I1,I2);
I=intersectZ(I,I3);
I=intersectZ(I,I4);
I=intersectZ(I,I5);
I=intersectZ(I,I6);
minAssZ(I);
↳ [1]:
↳   _[1]=d
↳   _[2]=c
↳ [2]:
↳   _[1]=b
↳   _[2]=a
↳ [3]:
↳   _[1]=2
↳   _[2]=c
↳ [4]:
↳   _[1]=3
↳ [5]:
↳   _[1]=13
↳   _[2]=b
↳ [6]:
↳   _[1]=17
↳   _[2]=a
ideal J=intersectZ(ideal(17,a),ideal(17,a2,b));
minAssZ(J);
↳ [1]:
↳   _[1]=17
↳   _[2]=a
ideal K=intersectZ(ideal(9,a+3),ideal(9,b+3));
minAssZ(K);
↳ [1]:
↳   _[1]=3
↳   _[2]=b
↳ [2]:
↳   _[1]=3
↳   _[2]=a
```

D.4.27.4 radicalZ

Procedure from library `primdecint.lib` (see [Section D.4.27 \[primdecint.lib\]](#), page 1256).

Usage: `radicalZ(I);` I ideal
 The coefficients must be ZZ.

Return: the radical of the input ideal

Example:

```
LIB "primdecint.lib";
ring R=integer,(a,b,c,d),dp;
ideal I1=9,a,b;
ideal I2=3,c;
ideal I3=11,2a,7b;
ideal I4=13a2,17b4;
ideal I5=9c5,6d5;
ideal I6=17,a15,b15,c15,d15;
ideal I=intersectZ(I1,I2);
I=intersectZ(I,I3);
I=intersectZ(I,I4);
I=intersectZ(I,I5);
I=intersectZ(I,I6);
radicalZ(I);
↪ _[1]=102bd
↪ _[2]=78ad
↪ _[3]=51bc
↪ _[4]=39ac
↪ _[5]=6abd
↪ _[6]=3abc
ideal J=intersectZ(ideal(17,a),ideal(17,a2,b));
radicalZ(J);
↪ _[1]=17
↪ _[2]=a
```

D.4.27.5 heightZ

Procedure from library `primdecint.lib` (see [Section D.4.27 \[primdecint.lib\]](#), page 1256).

Usage: `heightZ(I);` I ideal
 The coefficients must be ZZ.

Return: the height of the input ideal

Example:

```
LIB "primdecint.lib";
ring R=integer,(a,b,c,d),dp;
ideal I1=9,a,b;
ideal I2=3,c;
ideal I3=11,2a,7b;
ideal I4=13a2,17b4;
ideal I5=9c5,6d5;
ideal I6=17,a15,b15,c15,d15;
ideal I=intersectZ(I1,I2);
I=intersectZ(I,I3);
I=intersectZ(I,I4);
```

```

I=intersectZ(I,I5);
I=intersectZ(I,I6);
heightZ(I);
↪ 1

```

D.4.27.6 equidimZ

Procedure from library `primdecint.lib` (see [Section D.4.27 \[primdecint.lib\]](#), page 1256).

Usage: `equidimZ(I);` I ideal
 The coefficients must be ZZ.

Return: the part of minimal height

Example:

```

LIB "primdecint.lib";
ring R=integer,(a,b,c,d),dp;
ideal I1=9,a,b;
ideal I2=3,c;
ideal I3=11,2a,7b;
ideal I4=13a2,17b4;
ideal I5=9c5,6d5;
ideal I6=17,a15,b15,c15,d15;
ideal I=intersectZ(I1,I2);
I=intersectZ(I,I3);
I=intersectZ(I,I4);
I=intersectZ(I,I5);
I=intersectZ(I,I6);
equidimZ(I);
↪ _[1]=3

```

D.4.27.7 intersectZ

Procedure from library `primdecint.lib` (see [Section D.4.27 \[primdecint.lib\]](#), page 1256).

Return: the intersection of the input ideals

Note: this is an alternative to `intersect(I,J)` over integers, is faster for some examples and should be kept for debug purposes.

Example:

```

LIB "primdecint.lib";
ring R=integer,(a,b,c,d),dp;
ideal I1=9,a,b;
ideal I2=3,c;
ideal I3=11,2a,7b;
ideal I4=13a2,17b4;
ideal I5=9c5,6d5;

D.4.28 primitiv_lib

Library: primitiv.lib

Purpose: Computing a Primitive Element

Author: Martin Lamm, email: lamm@mathematik.uni-kl.de

Procedures:

D.4.28.1 primitive

Procedure from library `primitiv.lib` (see [Section D.4.28 \[primitiv.lib\]](#), page 1263).

Usage: `primitive(i); i ideal`

Assume: `i` is given by generators $m[1], \dots, m[n]$ such that for $j=1, \dots, n$
 - $m[j]$ is a polynomial in $k[x(1), \dots, x(j)]$
 - $m[j](a[1], \dots, a[j-1], x(j))$ is the minimal polynomial for $a[j]$ over $k(a[1], \dots, a[j-1])$
 (k the ground field of the current basering and $x(1), \dots, x(n)$ the ring variables).

Return: ideal j in $k[x(n)]$ with
 - $j[1]$ a minimal polynomial for a primitive element b of $k(a[1], \dots, a[n])$ over k ,
 - $j[2], \dots, j[n+1]$ polynomials in $k[x(n)]$ such that $j[i+1](b) = a[i]$ for $i=1, \dots, n$.

Note: the number of variables in the basering has to be exactly n , the number of given generators (i.e., minimal polynomials).
 If the ground field k has only a few elements it may happen that no linear combination of $a[1], \dots, a[n]$ is a primitive element. In this case `primitive(i)` returns the zero ideal, and one should use `primitive_extra(i)` instead.

Example:

```
LIB "primitiv.lib";
ring exring=0,(x,y),dp;
ideal i=x2+1,y2-x;           // compute Q(i,i^(1/2))=:L
ideal j=primitive(i);
j[1];                        // L=Q(a) with a=(-1)^(1/4)
⇨ y4+1
j[2];                        // i=a^2
⇨ y2
j[3];                        // i^(1/2)=a
⇨ y
// the 2nd element was already primitive!
j=primitive(ideal(x2-2,y2-3)); // compute Q(sqrt(2),sqrt(3))
j[1];
⇨ y4-10y2+1
j[2];
⇨ 1/2y3-9/2y
j[3];
⇨ -1/2y3+11/2y
// no element was primitive -- the calculation of primitive elements
// is based on a random choice.
```

See also: [Section D.4.28.2 \[primitive_extra\]](#), page 1264.

D.4.28.2 primitive_extra

Procedure from library `primitiv.lib` (see [Section D.4.28 \[primitiv.lib\]](#), page 1263).

Usage: `primitive_extra(i); i ideal`

Assume: The ground field of the basering is $k=Q$ or $k=Z/pZ$ and the ideal i is given by 2 generators f, g with the following properties:

f is the minimal polynomial of a in $k[x]$,

g is a polynomial in $k[x,y]$ s.th. $g(a,y)$ is the minpoly of b in $k(a)[y]$.

Here, x is the name of the first ring variable, y the name of the second.

Return: ideal j in $k[y]$ such that

$j[1]$ is the minimal polynomial for a primitive element c of $k(a,b)$ over k ,

$j[2]$ is a polynomial s.th. $j[2](c)=a$.

Note: While `primitive(i)` may fail for finite fields, `primitive_extra(i)` tries all elements of $k(a,b)$ and, hence, always finds a primitive element.

In order to do this (try all elements), field extensions like $\mathbb{Z}/p\mathbb{Z}(a)$ are not allowed for the ground field k .

`primitive_extra(i)` assumes that the second generator, g , is monic as polynomial in $(k[x])[y]$.

Example:

```
LIB "primitiv.lib";
ring exring=3,(x,y),dp;
ideal i=x2+1,y3+y2-1;
primitive_extra(i);
↪ _[1]=y6-y5+y4-y3-y-1
↪ _[2]=y5+y4+y2+y+1
ring extension=(3,y),x,dp;
minpoly=y6-y5+y4-y3-y-1;
number a=y5+y4+y2+y+1;
a^2;
↪ -1
factorize(x2+1);
↪ [1]:
↪   _[1]=1
↪   _[2]=x+(y5+y4+y2+y+1)
↪   _[3]=x+(-y5-y4-y2-y-1)
↪ [2]:
↪   1,1,1
factorize(x3+x2-1);
↪ [1]:
↪   _[1]=1
↪   _[2]=x+(y3+y+1)
↪   _[3]=x+(y5+y4+y2+1)
↪   _[4]=x+(-y5-y4-y3-y2-y-1)
↪ [2]:
↪   1,1,1,1
```

D.4.28.3 splitring

Procedure from library `primitiv.lib` (see [Section D.4.28 \[primitiv.lib\]](#), page 1263).

Usage: `splitring(f,L)`; f poly, L list of polys and/or ideals (optional)

Assume: f is univariate and irreducible over the active ring.

The active ring must allow an algebraic extension (e.g., it cannot be a transcendent ring extension of \mathbb{Q} or \mathbb{Z}/p).

Return: ring;

if called with a nonempty second parameter L , then in the output ring there is defined

a list `erg` (=L mapped to the new ring); if the minpoly of the active ring is non-zero, then the image of the primitive root of `f` in the output ring is appended as last entry of the list `erg`.

Note: If the old ring has no parameter, the name `a` is chosen for the parameter of `R` (if `a` is no ring variable; if it is, `b` is chosen, etc.; if `a, b, c, o` are ring variables, `splitring(f[,L])` produces an error message), otherwise the name of the parameter is kept and only the minimal polynomial is changed.
The names of the ring variables and the orderings are not affected.

Example:

```
LIB "primitiv.lib";
ring r=0,(x,y),dp;
def r1=splitring(x2-2);
setring r1; basering; // change to Q(sqrt(2))
⇨ // coefficients: QQ[a]/(a2-2)
⇨ // number of vars : 2
⇨ //          block 1 : ordering dp
⇨ //          : names x y
⇨ //          block 2 : ordering C
// change to Q(sqrt(2),sqrt(sqrt(2)))=Q(a) and return the transformed
// old parameter:
def r2=splitring(x2-a,a);
setring r2; basering; erg;
⇨ // coefficients: QQ[a]/(a4-2)
⇨ // number of vars : 2
⇨ //          block 1 : ordering dp
⇨ //          : names x y
⇨ //          block 2 : ordering C
⇨ [1]:
⇨      (a2)
⇨ [2]:
⇨      (a)
// the result is (a)^2 = (sqrt(sqrt(2)))^2
kill r1; kill r2;
```

D.4.29 realrad_lib

Library: realrad.lib

Purpose: Computation of real radicals

Author : Silke Spang

Overview: Algorithms about the computation of the real radical of an arbitrary ideal over the rational numbers and transcendental extensions thereof

Procedures:

D.4.29.1 realpoly

Procedure from library `realrad.lib` (see [Section D.4.29 \[realrad_lib\]](#), page 1266).

Usage: `realpoly(f)`; a univariate polynomial `f`;

Return: poly f, where f is the real part of the input f

Example:

```
LIB "realrad.lib";
ring r1 = 0,x,dp;
poly f=x5+16x2+x+1;
realpoly(f);
↪ x5+16x2+x+1
realpoly(f*(x4+2));
↪ x5+16x2+x+1
ring r2=0,(x,y),dp;
poly f=x6-3x4y2 + y6 + x2y2 -6y+5;
realpoly(f);
↪ x6-3x4y2+y6+x2y2-6y+5
ring r3=0,(x,y,z),dp;
poly f=x4y4-2x5y3z2+x6y2z4+2x2y3z-4x3y2z3+2x4yz5+z2y2-2z4yx+z6x2;
realpoly(f);
↪ x3yz2-x2y2+xz3-yz
realpoly(f*(x2+y2+1));
↪ x3yz2-x2y2+xz3-yz
```

D.4.29.2 realzero

Procedure from library `realrad.lib` (see [Section D.4.29 \[realrad.lib\]](#), page 1266).

Usage: realzero(j); a zero-dimensional ideal j

Return: j: a zero dimensional ideal, which is the real radical of i, if $\dim(i)=0$
 0: otherwise
 this acts via
 primary decomposition (i=1)
 listdecomp (i=2) or facstd (i=3)

Example:

```
LIB "realrad.lib";
//in non parametric fields
ring r=0,(x,y),dp;
ideal i=(y3+3y2+y+1)*(y2+4y+4)*(x2+1),(x2+y)*(x2-y2)*(x2+2xy+y2)*(y2+y+1);
realzero(i);
↪ _[1]=y4+5y3+7y2+3y+2
↪ _[2]=x4-x2y2+x2y-y3
ideal j=(y3+3y2+y+1)*(y2-2y+1),(x2+y)*(x2-y2);
realzero(j);
↪ _[1]=y4+2y3-2y2-1
↪ _[2]=x2y3+3x2y2+x2y-y3+x2-3y2-y-1
↪ _[3]=x4-x2y2+x2y-y3
//to get every path
ring r1=(0,t),(x,y),lp;
ideal m1=x2+1-t,y3+t2;
ideal m2=x2+t2+1,y2+t;
ideal m3=x2+1-t,y2-t;
ideal m4=x^2+1+t,y2-t;
ideal i=intersect(m1,m2,m3,m4);
realzero(i);
```

```

⇒ _[1]=y5+(-t)*y3+(t2)*y2+(-t3)
⇒ _[2]=x2+(-t+1)

```

D.4.29.3 realrad

Procedure from library `realrad.lib` (see [Section D.4.29 \[realrad.lib\]](#), page 1266).

Usage: `realrad(id)`, `id` an ideal of arbitrary dimension

Return: the real radical of `id`

Example:

```

LIB "realrad.lib";
ring r1=0,(x,y,z),lp;
//dimension 0
ideal i0=(x2+1)*(x3-2),(y3-2)*(y2+y+1),z3+2;
//dimension 1
ideal i1=(y3+3y2+y+1)*(y2+4y+4)*(x2+1),(x2+y)*(x2-y2)*(x2+2xy+y2)*(y2+y+1);
ideal i=intersect(i0,i1);
realrad(i);
⇒ _[1]=xy4+5xy3+7xy2+3xy+2x+y4z+5y3z+7y2z+3yz+2z
⇒ _[2]=-236x4y-590x4+236x2y3+354x2y2-590x2y+873y5z+573y5+873y4z2+4938y4z+31\

```

D.4.30 reesclos.lib

Library: `reesclos.lib`

Purpose: procedures to compute the int. closure of an ideal

Author: Tobias Hirsch, email: hirsch@math.tu-cottbus.de
 Janko Boehm, email: boehm@mathematik.uni-kl.de
 Magdaleen Marais, email: magdaleen@aims.ac.za

Overview: A library to compute the integral closure of an ideal I in a polynomial ring $R=k[x(1),\dots,x(n)]$ using the Rees Algebra $R[It]$ of I . It computes the integral closure of $R[It]$,

which is a graded subalgebra of $R[t]$. The degree- k -component is the integral closure of the k -th power of I .

In contrast to the previous version, the library uses 'normal.lib' to compute the integral closure of $R[It]$. This improves the performance considerably.

Procedures:

D.4.30.1 ReesAlgebra

Procedure from library `reesclos.lib` (see [Section D.4.30 \[reesclos.lib\]](#), page 1268).

Usage: `ReesAlgebra (I)`; I = ideal

Return: The Rees algebra $R[It]$ as an affine ring, where I is an ideal in R . The procedure returns a list containing two rings:
 [1]: a ring, say RR ; in the ring an ideal \ker such that $R[It]=RR/\ker$
 [2]: a ring, say Kxt ; the basering with additional variable t containing an ideal map I that defines the map $RR \rightarrow Kxt$

Example:

```
LIB "reesclos.lib";
ring R = 0,(x,y),dp;
ideal I = x2,xy4,y5;
list L = ReesAlgebra(I);
def Rees = L[1];          // defines the ring Rees, containing the ideal ker
setring Rees;            // passes to the ring Rees
Rees;
⇒ // coefficients: QQ
⇒ // number of vars : 5
⇒ //          block 1 : ordering dp
⇒ //          : names  x y U(1) U(2) U(3)
⇒ //          block 2 : ordering C
ker;                      // R[It] is isomorphic to Rees/ker
⇒ ker[1]=y*U(2)-x*U(3)
⇒ ker[2]=y^3*U(1)*U(3)-U(2)^2
⇒ ker[3]=y^4*U(1)-x*U(2)
⇒ ker[4]=x*y^2*U(1)*U(3)^2-U(2)^3
⇒ ker[5]=x^2*y*U(1)*U(3)^3-U(2)^4
⇒ ker[6]=x^3*U(1)*U(3)^4-U(2)^5
```

D.4.30.2 normalI

Procedure from library `reesclos.lib` (see [Section D.4.30 \[reesclos.lib\]](#), page 1268).

Usage: `normalI (I [,p [,r [,l]]])`; I an ideal, p , r , and l optional integers

Return: the integral closure of I , ..., I^p , where I is an ideal in the polynomial ring $R=k[x(1),\dots,x(n)]$. If p is not given, or $p==0$, compute the closure of all powers up to the maximum degree in t occurring in the closure of $R[It]$ (so this is the last power whose closure is not just the sum/product of the smaller). If r is given and $r==1$, `normalI` starts with a check whether I is already a radical ideal.
 If $l==1$ then `locNormal` instead of `normal` is used to compute normalization. The result is a list containing the closure of the desired powers of I as ideals of the basering.

Display: The procedure displays more comments for higher `printlevel`.

Example:

```
LIB "reesclos.lib";
ring R=0,(x,y),dp;
ideal I = x2,xy4,y5;
list J = normalI(I);
I;
⇒ I[1]=x2
⇒ I[2]=xy4
⇒ I[3]=y5
J;                      // J[1] is the integral closure of I
⇒ [1]:
```

```

↳   _[1]=x2
↳   _[2]=xy4
↳   _[3]=y5
↳   _[4]=xy3

```

D.4.31 rstandard.lib

Library: rstandard.lib

Purpose: Computes Janet bases and border bases for ideals

Authors: Shamsa Kanwal lotus_zone16@yahoo.com
Gerhard Pfister pfister@mathematik.uni-kl.de

Overview: Computing Janet bases and border bases for any ordering using the idea of r-standard bases (defined by V. Gerdt)

References:

- [1] A. Kehrein, M. Kreuzer, L. Robbiano: An algebrists view on border bases, in: A. Dickenstein and I. Emiris (eds.), Solving Polynomial Equations: Foundations, Algorithms and Applications, Springer, Heidelberg 2005, 169-202.

Procedures:

D.4.31.1 borderBasis

Procedure from library `rstandard.lib` (see [Section D.4.31 \[rstandard.lib\]](#), page 1270).

Usage: borderBasis(I); I is an ideal.

Return: ideal, a border basis for I.

Purpose: Computes a border basis for the ideal given by the generators in I.

Example:

```

LIB "rstandard.lib";
ring R=32003,(x,y,z),ds;
poly f=x3y+x5+x3y2+2x2y3+x2yz2+xy5+x12+y16+z20;

D.4.31.2 modBorder

Procedure from library `rstandard.lib` (see [Section D.4.31 \[rstandard.lib\]](#), page 1270).

Usage: `modBorder(I,i)`; I is an ideal, i an integer.

Return: ideal, a border basis for I using modular methods.

Purpose: Computes a border basis for the ideal given by the generators in I using modular techniques.

If second argument is 0 then the result is not verified.

Example:

```

LIB "rstandard.lib";
ring R=0,(x,y,z),ds;
poly f=x3y+x5+x3y2+2x2y3+x2yz2+xy5+x12+y16+z20;
ideal i= jacob(f);
i=i,f;
ideal j=modBorder(i,1); j;

```

See also: [Section D.4.31.1 \[borderBasis\]](#), page 1270.

D.4.31.3 rJanet

Procedure from library `rstandard.lib` (see [Section D.4.31 \[rstandard.lib\]](#), page 1270).

Usage: `rJanet(I)`; `I` is an ideal.

Return: ideal, a Janet basis for `I`.

Purpose: Computes a Janet basis for the ideal given by the generators in `I` for any ordering.

Example:

```

LIB "rstandard.lib";
ring R= 32003,(a,b,c,d,e,f,g),dp;
ideal i=
a+b+c+d+e+f+g,
ab+bc+cd+de+ef+fg+ga,
abc+bcd+cde+fde+efg+fga+gab,
abcd+bcde+cdef+defg+efga+fgab+gabc,
abcde+bcdef+cdefg+defga+efgab+fgabc+gabcd,
abcdef+bcdefg+cdefga+defgab+efgabc+fgabcd+gabcde,
abcdefg-1;
ideal j = rJanet(i);  j;

```

```

See also: [Section D.4.31.4 \[modJanet\]](#), page 1379.

D.4.31.4 modJanet

Procedure from library `rstandard.lib` (see [Section D.4.31 \[rstandard.lib\]](#), page 1270).

Usage: `modJanet(I,i)`; `I` is an ideal, `i` an integer (optional).

Return: ideal, a Janet basis for `I` using modular methods.

Purpose: Computes a Janet basis for the ideal given by the generators in `I` using modular techniques.
If second argument is 0 then the result is not verified.

Example:

```

LIB "rstandard.lib";
ring R=0,(t,x,y,z),ds;
ideal i=
5t3x2z+2t2y3x5,
7y+4x2y+y2x+2zt,

```

See also: [Section D.4.31.3 \[rJanet\]](#), page 1309.

D.4.32 sagbi.lib

Library: sagbi.lib

Purpose: Compute SAGBI basis (subalgebra bases analogous to Groebner bases for ideals) of a subalgebra

Authors: Jan Hackfeld, Jan.Hackfeld@rwth-aachen.de
 Gerhard Pfister, pfister@mathematik.uni-kl.de
 Viktor Levandovskyy, levandov@math.rwth-aachen.de

Overview: SAGBI stands for 'subalgebra bases analogous to Groebner bases for ideals'. SAGBI bases provide important tools for working with finitely presented subalgebras of a polynomial ring. Note, that in contrast to Groebner bases, SAGBI bases may be infinite.

References:

Ana Bravo: Some Facts About Canonical Subalgebra Bases, MSRI Publications 51, p. 247-254

Procedures: See also: [Section D.4.2 \[algebra.lib\]](#), page 1005.

D.4.32.1 sagbiSPoly

Procedure from library `sagbi.lib` (see [Section D.4.32 \[sagbi.lib\]](#), page 1380).

Usage: `sagbiSPoly(A[, returnRing, meth]);` A is an ideal, returnRing and meth are integers.

Return: ideal or ring

Assume: basering is not a qring

Purpose: Returns SAGBI S-polynomials of the leading terms of a given ideal A if returnRing=0. Otherwise returns a new ring containing the ideals algebraicRelations and spolynomial, where these objects are explained by their name. See the example on how to access these objects. The other optional argument meth determines which method is used for computing the algebraic relations.

- If meth=0 (default), the procedure std is used.
- If meth=1, the procedure slimgb is used.
- If meth=2, the procedure uses toric_ideal.

Example:

```
LIB "sagbi.lib";
ring r= 0,(x,y),dp;
ideal A=x*y+x,x*y^2,y^2+y,x^2+x;
//----- Compute the SAGBI S-polynomials only
sagbiSPoly(A);
⇒ _[1]=x2y-xy2+x2-xy
⇒ _[2]=x2y3+1/2xy4+1/2x2y2+xy3+1/2xy2
//----- Extended ring is to be returned, which contains
// the ideal of algebraic relations and the ideal of the S-polynomials
def rNew=sagbiSPoly(A,1); setring rNew;
spolynomial;
⇒ spolynomial[1]=x^2*y-x*y^2+x^2-x*y
⇒ spolynomial[2]=x^2*y^3+1/2*x*y^4+1/2*x^2*y^2+x*y^3+1/2*x*y^2
algebraicRelations;
⇒ algebraicRelations[1]=@y(1)^2-@y(3)*@y(4)
⇒ algebraicRelations[2]=@y(3)^2*@y(4)-@y(2)^2
//----- Now we verify that the substitution of A[i] into @y(i)
```

```
// results in the spolynomialS listed above
ideal A=fetch(r,A);
map phi=rNew,x,y,A;
ideal spolynomialS2=simplify(phi(algebraicRelations),1);
spolynomialS2;
↳ spolynomialS2[1]=x^2*y-x*y^2+x^2-x*y
↳ spolynomialS2[2]=x^2*y^3+1/2*x*y^4+1/2*x^2*y^2+x*y^3+1/2*x*y^2
```

D.4.32.2 sagbiReduce

Procedure from library `sagbi.lib` (see [Section D.4.32 \[sagbi.lib\]](#), page 1380).

Usage: `sagbiReduce(I, A[, tr, mt]);` I, A ideals, tr, mt optional integers

Return: ideal of remainders of I after SAGBI reduction by A

Assume: basering is not a qring

Purpose:

The optional argument `tr=tailred` determines whether tail reduction will be performed.

- If (`tailred=0`), no tail reduction is done.
- If (`tailred<>0`), tail reduction is done.

The other optional argument `meth` determines which method is used for Groebner basis computations.

- If `mt=0` (default), the procedure `std` is used.
- If `mt=1`, the procedure `slimgb` is used.

Example:

```
LIB "sagbi.lib";
ring r=0,(x,y,z),dp;
ideal A=x2,2*x2y+y,x3y2;
poly p1=x^5+x2y+y;
poly p2=x^16+x^12*y^5+6*x^8*y^4+x^6+y^4+3;
ideal P=p1,p2;
//-----
//SAGBI reduction of polynomial p1 by algebra A.
//Default call, that is, no tail-reduction is done.
sagbiReduce(p1,A);
↳ x5+x2y+y
//-----
//SAGBI reduction of set of polynomials P by algebra A,
//now tail-reduction is done.
sagbiReduce(P,A,1);
↳ _[1]=x5+1/2y
↳ _[2]=x6y5-8y4
```

D.4.32.3 sagbi

Procedure from library `sagbi.lib` (see [Section D.4.32 \[sagbi.lib\]](#), page 1380).

Usage: `sagbi(A[, tr, mt]);` A ideal, tr, mt optional integers

Return: ideal, a SAGBI basis for A

Assume: basering is not a qring

Purpose: Computes a SAGBI basis for the subalgebra given by the generators in A.

The optional argument `tr=tailred` determines whether tail reduction will be performed.

- If (`tailred=0`), no tail reduction is performed,
- If (`tailred<>0`), tail reduction is performed.

The other optional argument `meth` determines which method is used for Groebner basis computations.

- If `mt=0` (default), the procedure `std` is used.
- If `mt=1`, the procedure `slimgb` is used.

Example:

```
LIB "sagbi.lib";
ring r= 0,(x,y,z),dp;
ideal A=x2,y2,xy+y;
//Default call, no tail-reduction is done.
sagbi(A);
↪ _[1]=x2
↪ _[2]=y2
↪ _[3]=xy+y
↪ _[4]=xy2+1/2y2
//-----
//Call with tail-reduction and method specified.
sagbi(A,1,0);
↪ _[1]=x2
↪ _[2]=y2
↪ _[3]=xy+y
↪ _[4]=xy2
```

D.4.32.4 sagbiPart

Procedure from library `sagbi.lib` (see [Section D.4.32 \[sagbi.lib\]](#), page 1380).

Usage: `sagbiPart(A, k,[tr, mt]);` `A` is an ideal, `k`, `tr` and `mt` are integers

Return: ideal

Assume: basering is not a qring

Purpose: Performs `k` iterations of the SAGBI construction algorithm for the subalgebra given by the generators given by `A`.

The optional argument `tr=tailred` determines if tail reduction will be performed.

- If (`tailred=0`), no tail reduction is performed,
- If (`tailred<>0`), tail reduction is performed.

The other optional argument `meth` determines which method is used for Groebner basis computations.

- If `mt=0` (default), the procedure `std` is used.
- If `mt=1`, the procedure `slimgb` is used.

Example:

```
LIB "sagbi.lib";
ring r= 0,(x,y,z),dp;
//The following algebra does not have a finite SAGBI basis.
ideal A=x,xy-y2,xy2;
//-----
//Call with two iterations, no tail-reduction is done.
sagbiPart(A,2);
↪ //SAGBI construction algorithm stopped as it reached the limit of 2 itera\
```

```

        tions.
    ↪ //In general the returned generators are no SAGBI basis for the given alg\
        ebra.
    ↪ _[1]=x
    ↪ _[2]=xy-y2
    ↪ _[3]=xy2
    ↪ _[4]=2xy3-y4
    ↪ _[5]=3xy5-y6
    ↪ _[6]=xy4
    ↪ //-----
    ↪ //Call with three iterations, tail-reduction and method 0.
    ↪ sagbiPart(A,3,1,0);
    ↪ //SAGBI construction algorithm stopped as it reached the limit of 3 itera\
        tions.
    ↪ //In general the returned generators are no SAGBI basis for the given alg\
        ebra.
    ↪ _[1]=x
    ↪ _[2]=xy-y2
    ↪ _[3]=xy2
    ↪ _[4]=2xy3-y4
    ↪ _[5]=3xy5-y6
    ↪ _[6]=xy4
    ↪ _[7]=5xy9-y10
    ↪ _[8]=xy8
    ↪ _[9]=4xy7-y8
    ↪ _[10]=xy6

```

D.4.32.5 algebraicDependence

Procedure from library `sagbi.lib` (see [Section D.4.32 \[sagbi.lib\]](#), page 1380).

Usage: `algebraicDependence(I,it)`; I an an ideal, it is an integer

Return: ring

Assume: basering is not a qring

Purpose: Returns a ring containing the ideal `algDep`, which contains possibly some algebraic dependencies of the elements of I obtained through it iterations of the SAGBI construction algorithms. See the example on how to access these objects.

Example:

```

LIB "sagbi.lib";
ring r= 0,(x,y),dp;
//The following algebra does not have a finite SAGBI basis.
ideal I=x^2, xy-y2, xy2;
//-----
//Call with two iterations
def DI = algebraicDependence(I,2);
    ↪ //AlgDep-1- initialisation and precomputation
    ↪ //AlgDep-2- call of SAGBI construction algorithm
    ↪ //SAGBI construction algorithm stopped as it reached the limit of 2 itera\
        tions.
    ↪ //In general the returned generators are no SAGBI basis for the given alg\

```

```

    ebra.
    ↪ //AlgDep-3- postprocessing of results
    setring DI; algDep;
    ↪ algDep[1]=0
    // we see that no dependency has been seen so far
    //-----
    //Call with two iterations
    setring r; kill DI;
    def DI = algebraicDependence(I,3);
    ↪ //AlgDep-1- initialisation and precomputation
    ↪ //AlgDep-2- call of SAGBI construction algorithm
    ↪ //SAGBI construction algorithm stopped as it reached the limit of 3 itera\
    tions.
    ↪ //In general the returned generators are no SAGBI basis for the given alg\
    ebra.
    ↪ //AlgDep-3- postprocessing of results
    setring DI; algDep;
    ↪ algDep[1]=0
    map F = DI,x,y,x^2, xy-y2, xy2;
    F(algDep); // we see that it is a dependence indeed
    ↪ _[1]=0

```

D.4.33 sing4ti2.lib

Library: sing4ti2.lib

Purpose: Communication Interface to 4ti2

Authors: Thomas Kahle , kahle@mis.mpg.de
 Anne Fruehbis-Krueger, anne@math.uni-hannover.de

Note: This library uses the external program 4ti2 for calculations
 and the standard unix tools sed and awk for conversion of
 the returned result

Procedures:

D.4.33.1 markov4ti2

Procedure from library `sing4ti2.lib` (see [Section D.4.33 \[sing4ti2.lib\]](#), page 1385).

Usage: markov4ti2(A[,i]);
 A=intmat
 i=int

Assume: - A is a matrix with integer entries which describes the lattice
 as $\ker(A)$, if second argument is not present,
 as left image $\text{Im}(A) = \{zA, z \in \mathbb{Z}^k\}(!)$, if second argument is a positive integer
 - number of variables of basering equals number of columns of A
 (for $\ker(A)$) resp. of rows of A (for $\text{Im}(A)$)

Create: files sing4ti2.mat, sing4ti2.lat, sing4ti2.mar in the current
 directory (I/O files for communication with 4ti2)

Note: input rules for 4ti2 also apply to input to this procedure
 hence $\ker(A) = \{x \mid Ax=0\}$ and $\text{Im}(A) = \{xA\}$

Return: toric ideal specified by Markov basis thereof

Example:

```
LIB "sing4ti2.lib";
ring r=0,(x,y,z),dp;
matrix M[2][3]=0,1,2,2,1,0;
markov4ti2(M);
  ↳ _[1]=-y2+xz
matrix N[1][3]=1,2,1;
markov4ti2(N,1);
  ↳ _[1]=xy2z-1
  ↳ _[2]=xy2z-1
```

D.4.33.2 hilbert4ti2

Procedure from library `sing4ti2.lib` (see [Section D.4.33 \[sing4ti2.lib\]](#), page 1385).

Usage: `hilbert4ti2(A[,i]);`
 `A=intmat`
 `i=int`

Assume: - A is a matrix with integer entries which describes the lattice
 as $\ker(A)$, if second argument is not present,
 as the left image $\text{Im}(A) = \{zA : z \in \mathbb{Z}^k\}$, if second argument is a positive integer
 - number of variables of basering equals number of columns of A
 (for $\ker(A)$) resp. of rows of A (for $\text{Im}(A)$)

Create: temporary files `sing4ti2.mat`, `sing4ti2.lat`, `sing4ti2.mar`
 in the current directory (I/O files for communication with 4ti2)

Note: input rules for 4ti2 also apply to input to this procedure
 hence $\ker(A) = \{x \mid Ax=0\}$ and $\text{Im}(A) = \{xA\}$

Return: toric ideal specified by Hilbert basis thereof

Example:

```
LIB "sing4ti2.lib";
ring r=0,(x1,x2,x3,x4,x5,x6,x7,x8,x9),dp;
matrix M[7][9]=1,1,1,-1,-1,-1,0,0,0,1,1,1,0,0,0,-1,-1,-1,0,1,1,-1,0,0,-1,0,0,1,0,1,0
hilbert4ti2(M);
  ↳ _[1]=x12*x3*x5*x62*x7*x82-1
  ↳ _[2]=x1*x32*x42*x5*x82*x9-1
  ↳ _[3]=x22*x3*x42*x5*x7*x92-1
  ↳ _[4]=x1*x22*x5*x62*x72*x9-1
  ↳ _[5]=x1*x2*x3*x4*x5*x6*x7*x8*x9-1
```

D.4.33.3 graver4ti2

Procedure from library `sing4ti2.lib` (see [Section D.4.33 \[sing4ti2.lib\]](#), page 1385).

Usage: `graver4ti2(A[,i]);`
 `A=intmat`
 `i=int`

Assume: - A is a matrix with integer entries which describes the lattice
 as $\ker(A)$, if second argument is not present,

as the left image $\text{Im}(A) = \{zA : z \in \mathbb{Z}^k\}$, if second argument is a positive integer - number of variables of basering equals number of columns of A (for $\ker(A)$) resp. of rows of A (for $\text{Im}(A)$)

Create: temporary files `sing4ti2.mat`, `sing4ti2.lat`, `sing4ti2.gra` in the current directory (I/O files for communication with 4ti2)

Note: input rules for 4ti2 also apply to input to this procedure
hence $\ker(A) = \{x \mid Ax = 0\}$ and $\text{Im}(A) = \{xA\}$

Return: toric ideal specified by Graver basis thereof

Example:

```
LIB "sing4ti2.lib";
ring r=0,(x,y,z,w),dp;
matrix M[2][4]=0,1,2,3,3,2,1,0;
graver4ti2(M);
⇨ _[1]=-y2+xz
⇨ _[2]=-y3+x2w
⇨ _[3]=-yz+xw
⇨ _[4]=-z2+yw
⇨ _[5]=-z3+xw2
```

D.4.34 symodstd.lib

Library: `symodstd.lib`

Purpose: Procedures for computing Groebner basis of ideals being invariant under certain variable permutations.

Author: Stefan Steidel, steidel@mathematik.uni-kl.de

Overview: A library for computing the Groebner basis of an ideal in the polynomial ring over the rational numbers, that is invariant under certain permutations of the variables, using the symmetry and modular methods. More precisely let $I = \langle f_1, \dots, f_r \rangle$ be an ideal in $\mathbb{Q}[x(1), \dots, x(n)]$ and σ a permutation of order k in $\text{Sym}(n)$ such that $\sigma(I) = I$. We assume that $\sigma(\{f_1, \dots, f_r\}) = \{f_1, \dots, f_r\}$. This can always be obtained by adding $\sigma(f_i)$ to $\{f_1, \dots, f_r\}$.

To compute a standard basis of I we apply a modification of the modular version of the standard basis algorithm (improving the calculations in positive characteristic). Therefore we only allow primes p such that $p-1$ is divisible by k . This guarantees the existence of a k -th primitive root of unity in $\mathbb{Z}/p\mathbb{Z}$.

Procedures:

D.4.34.1 genSymId

Procedure from library `symodstd.lib` (see [Section D.4.34 \[symodstd.lib\]](#), page 1387).

Usage: `genSymId(I, sigma)`; I ideal, σ intvec

Assume: `size(sigma) = nvars(basering) =: n`

Return: ideal J such that $\sigma(J) = J$ and J includes I

Note: σ is a permutation of the variables of the basering, i.e.
 $\sigma: \text{var}(i) \rightarrow \text{var}(\sigma[i])$, $1 \leq i \leq n$.

Example:

```

LIB "symodstd.lib";
ring R = 0,(u,v,w,x,y),dp;
intvec pi = 2,3,4,5,1;
ideal I = u2v + x3y - w2;
genSymId(I,pi);
↪ _[1]=x3y+u2v-w2
↪ _[2]=uy3+v2w-x2
↪ _[3]=u3v+w2x-y2
↪ _[4]=v3w+x2y-u2
↪ _[5]=w3x+uy2-v2

```

D.4.34.2 isSymmetric

Procedure from library `symodstd.lib` (see [Section D.4.34 \[symodstd.lib\]](#), page 1387).

Usage: `isSymmetric(I,sigma)`; I ideal, sigma intvec

Assume: `size(sigma) = nvars(basing) =: n`

Return: 1, if the set of generators of I is invariant under sigma;
0, if the set of generators of I is not invariant under sigma

Note: sigma is a permutation of the variables of the basing, i.e.
sigma: $\text{var}(i) \rightarrow \text{var}(\text{sigma}[i])$, $1 \leq i \leq n$.

Example:

```

LIB "symodstd.lib";
ring R = 0,x(1..5),dp;
ideal I = cyclic(5);
intvec pi = 2,3,4,5,1;
isSymmetric(I,pi);
↪ 1
intvec tau = 2,5,1,4,3;
isSymmetric(I,tau);
↪ 0

```

D.4.34.3 primRoot

Procedure from library `symodstd.lib` (see [Section D.4.34 \[symodstd.lib\]](#), page 1387).

Usage: `primRoot(p,k)`; p,k integers

Assume: p is a prime and k divides p-1.

Return: int: a k-th primitive root of unity in $\mathbb{Z}/p\mathbb{Z}$

Example:

```

LIB "symodstd.lib";
primRoot(181,10);
↪ 56
ring R = 2147482801, x, lp;
number a = primRoot(2147482801,5);
a;
↪ -159774741
a^2;
↪ 140354890

```

```

a^3;
↦ 260989846
a^4;
↦ -241569996
a^5;
↦ 1

```

D.4.34.4 eigenvalues

Procedure from library `symodstd.lib` (see [Section D.4.34 \[symodstd.lib\], page 1387](#)).

Usage: `eigenvalues(I,sigma)`; I ideal, sigma intvec

Assume: `size(sigma) = nvars(basering) =: n`

Return: list of eigenvalues of generators of I under permutation sigma

Note: sigma is a permutation of the variables of the basering, i.e. sigma: `var(i) → var(sigma[i])`, $1 \leq i \leq n$.

Example:

```

LIB "symodstd.lib";
ring R = 11, x(1..5), dp;
poly p1 = x(1)+x(2)+x(3)+x(4)+x(5);
poly p2 = x(1)+4*x(2)+5*x(3)-2*x(4)+3*x(5);
poly p3 = x(1)+5*x(2)+3*x(3)+4*x(4)-2*x(5);
poly p4 = x(1)-2*x(2)+4*x(3)+3*x(4)+5*x(5);
poly p5 = x(1)+3*x(2)-2*x(3)+5*x(4)+4*x(5);
ideal I = p1,p2,p3,p4,p5;
intvec tau = 2,3,4,5,1;
eigenvalues(I,tau);
↦ [1]:
↦ 1
↦ [2]:
↦ 3
↦ [3]:
↦ -2
↦ [4]:
↦ 5
↦ [5]:
↦ 4

```

D.4.34.5 symmStd

Procedure from library `symodstd.lib` (see [Section D.4.34 \[symodstd.lib\], page 1387](#)).

Usage: `symmStd(I,sigma,#)`; I ideal, sigma intvec

Assume: `size(sigma) = nvars(basering) =: n`, basering has an `order(sigma)`-th primitive root of unity α (if `char(basering) > 0`) and `sigma(I) = I`

Return: ideal, a standard basis of I

Note: Assuming that the ideal I is invariant under the variable permutation sigma and the basering has an `order(sigma)`-th primitive root of unity the procedure uses linear transformation of variables in order to improve standard basis computation. If `char(basering) = 0` all computations are done in the polynomial ring over the smallest field extension that has an `order(sigma)`-th primitive root of unity.

Example:

```

LIB "symodstd.lib";
ring R = 0, x(1..4), dp;
ideal I = cyclic(4);
I;
↪ I[1]=x(1)+x(2)+x(3)+x(4)
↪ I[2]=x(1)*x(2)+x(2)*x(3)+x(1)*x(4)+x(3)*x(4)
↪ I[3]=x(1)*x(2)*x(3)+x(1)*x(2)*x(4)+x(1)*x(3)*x(4)+x(2)*x(3)*x(4)
↪ I[4]=x(1)*x(2)*x(3)*x(4)-1
intvec pi = 2,3,4,1;
ideal sI = symmStd(I,pi);
sI;
↪ sI[1]=x(1)+x(2)+x(3)+x(4)
↪ sI[2]=x(2)^2+2*x(2)*x(4)+x(4)^2
↪ sI[3]=x(2)*x(3)^2+x(3)^2*x(4)-x(2)*x(4)^2-x(4)^3
↪ sI[4]=x(2)*x(3)*x(4)^2+x(3)^2*x(4)^2-x(2)*x(4)^3+x(3)*x(4)^3-x(4)^4-1
↪ sI[5]=x(2)*x(4)^4+x(4)^5-x(2)-x(4)
↪ sI[6]=x(3)^3*x(4)^2+x(3)^2*x(4)^3-x(3)-x(4)
↪ sI[7]=x(3)^2*x(4)^4+x(2)*x(3)-x(2)*x(4)+x(3)*x(4)-2*x(4)^2
ring S = 31, (x,y,z), dp;
ideal J;
J[1] = xy-y2+xz;
J[2] = xy+yz-z2;
J[3] = -x2+xz+yz;
intvec tau = 3,1,2;
ideal sJ = symmStd(J,tau);
sJ;
↪ sJ[1]=y2-xz+yz-z2
↪ sJ[2]=xy+yz-z2
↪ sJ[3]=x2-xz-yz
↪ sJ[4]=yz2-z3
↪ sJ[5]=xz2
↪ sJ[6]=z4

```

D.4.34.6 syModStd

Procedure from library `symodstd.lib` (see [Section D.4.34 \[symodstd.lib\]](#), page 1387).

Usage: `syModStd(I,sigma);` I ideal, sigma intvec

Assume: `size(sigma) = nvars(basing)` and `sigma(I) = I`. If `size(#)` > 0, then # contains either 1, 2 or 4 integers such that

- #[1] is the number of available processors for the computation,
- #[2] is an optional parameter for the exactness of the computation, if #[2] = 1, the procedure computes a standard basis for sure,
- #[3] is the number of primes until the first lifting,
- #[4] is the constant number of primes between two liftings until the computation stops.

Return: ideal, a standard basis of I if no warning appears;

Note: The procedure computes a standard basis of the ideal I (over the rational numbers) by using modular methods and the fact that I is invariant under the variable permutation sigma.

By default the procedure computes a standard basis of I for sure, but if the optional parameter $\#[2] = 0$, it computes a standard basis of I with high probability.

The procedure distinguishes between different variants for the standard basis computation in positive characteristic depending on the ordering of the basering, the parameter $\#[2]$ and if the ideal I is homogeneous.

- variant = 1, if I is homogeneous,
- variant = 2, if I is not homogeneous, 1-block-ordering,
- variant = 3, if I is not homogeneous, complicated ordering (lp or > 1 block),
- variant = 4, if I is not homogeneous, ordering lp, $\dim(I) = 0$.

Example:

```
LIB "symodstd.lib";
ring R1 = 0, (x,y,z), dp;
ideal I;
I[1] = -2xyz4+xz5+xz;
I[2] = -2xyz4+yz5+yz;
intvec sigma = 2,1,3;
ideal sI = syModStd(I,sigma);
sI;
↪ sI[1]=x2yz-xy2z
↪ sI[2]=xz5-yz5+xz-yz
↪ sI[3]=xyz4-1/2yz5-1/2yz
↪ sI[4]=y2z5-1/2yz6-xyz+y2z-1/2yz2
ring R2 = 0, x(1..4), dp;
ideal I = cyclic(4);
I;
↪ I[1]=x(1)+x(2)+x(3)+x(4)
↪ I[2]=x(1)*x(2)+x(2)*x(3)+x(1)*x(4)+x(3)*x(4)
↪ I[3]=x(1)*x(2)*x(3)+x(1)*x(2)*x(4)+x(1)*x(3)*x(4)+x(2)*x(3)*x(4)
↪ I[4]=x(1)*x(2)*x(3)*x(4)-1
intvec pi = 2,3,4,1;
ideal sJ1 = syModStd(I,pi,1);
ideal sJ2 = syModStd(I,pi,1,0);
size(reduce(sJ1,sJ2));
↪ 0
size(reduce(sJ2,sJ1));
↪ 0
```

D.4.35 toric_lib

Library: toric.lib

Purpose: Standard Basis of Toric Ideals

Author: Christine Theis, email: ctheis@math.uni-sb.de

Procedures:

D.4.35.1 toric_ideal

Procedure from library `toric.lib` (see [Section D.4.35 \[toric_lib\]](#), page 1391).

Usage: `toric_ideal(A,alg);` A intmat, alg string
`toric_ideal(A,alg,prsv);` A intmat, alg string, prsv intvec

Return: ideal: standard basis of the toric ideal of A

Note: These procedures return the standard basis of the toric ideal of A with respect to the term ordering in the current basering. Not all term orderings are supported: The usual global term orderings may be used, but no block orderings combining them.

One may call the procedure with several different algorithms:

- the algorithm of Conti/Traverso using elimination (ect),
- the algorithm of Pottier (pt),
- an algorithm of Bigatti/La Scala/Robbiano (blr),
- the algorithm of Hosten/Sturmfels (hs),
- the algorithm of DiBiase/Urbanke (du).

The argument 'alg' should be the abbreviation for an algorithm as above: ect, pt, blr, hs or du.

If 'alg' is chosen to be 'blr' or 'hs', the algorithm needs a vector with positive coefficients in the row space of A.

If no row of A contains only positive entries, one has to use the second version of `toric_ideal` which takes such a vector as its third argument.

For the mathematical background, see

[Section C.6 \[Toric ideals and integer programming\], page 782.](#)

Example:

```
LIB "toric.lib";
ring r=0,(x,y,z),dp;
// call with two arguments
intmat A[2][3]=1,1,0,0,1,1;
A;
  ↳ 1,1,0,
  ↳ 0,1,1
ideal I=toric_ideal(A,"du");
I;
  ↳ I[1]=xz-y
I=toric_ideal(A,"blr");
  ↳ ? The chosen algorithm needs a positive vector in the row space of the\
    matrix.
  ↳ ? leaving toric.lib::toric_ideal_1 (0)
  ↳ ? leaving toric.lib::toric_ideal (704)
I;
  ↳ I[1]=xz-y
// call with three arguments
intvec prsv=1,2,1;
I=toric_ideal(A,"blr",prsv);
I;
  ↳ I[1]=xz-y
```

See also: [Section C.6.1 \[Toric ideals\], page 782](#); [Section D.4.13 \[intprog.lib\], page 1120](#); [Section D.4.35.2 \[toric_std\], page 1392](#).

D.4.35.2 toric_std

Procedure from library `toric.lib` (see [Section D.4.35 \[toric.lib\], page 1391](#)).

Usage: `toric_std(I);` I ideal

Return: ideal: standard basis of I

Note: This procedure computes the standard basis of I using a specialized Buchberger algorithm. The generating system by which I is given has to consist of binomials of the form $x^u - x^v$. There is no real check if I is toric. If I is generated by binomials of the above form, but not toric, `toric_std` computes an ideal ‘between’ I and its saturation with respect to all variables.

For the mathematical background, see

[Section C.6 \[Toric ideals and integer programming\], page 782.](#)

Example:

```
LIB "toric.lib";
ring r=0,(x,y,z),wp(3,2,1);
// call with toric ideal (of the matrix A=(1,1,1))
ideal I=x-y,x-z;
ideal J=toric_std(I);
J;
⇒ J[1]=y-z
⇒ J[2]=x-z
// call with the same ideal, but badly chosen generators:
// 1) not only binomials
I=x-y,2x-y-z;
J=toric_std(I);
⇒ ? Generator 2 of the input ideal is no difference of monomials.
⇒ ? leaving toric.lib::toric_std (0)
// 2) binomials whose monomials are not relatively prime
I=x-y,xy-yz,y-z;
J=toric_std(I);
⇒ Warning: The monomials of generator 2 of the input ideal are not relative\
ly prime.
J;
⇒ J[1]=y-z
⇒ J[2]=x-z
// call with a non-toric ideal that seems to be toric
I=x-yz,xy-z;
J=toric_std(I);
J;
⇒ J[1]=y2-1
⇒ J[2]=x-yz
// comparison with real standard basis and saturation
ideal H=std(I);
H;
⇒ H[1]=x-yz
⇒ H[2]=y2z-z
LIB "elim.lib";
sat_with_exp(H,xyz);
⇒ [1]:
⇒ _[1]=x-yz
⇒ _[2]=y2-1
⇒ [2]:
⇒ 1
```

See also: [Section C.6.1 \[Toric ideals\], page 782](#); [Section D.4.13 \[intprog.lib\], page 1120](#); [Section D.4.35.1 \[toric_ideal\], page 1391](#); [Section D.4.35 \[toric.lib\], page 1391](#).

D.5 Algebraic geometry

D.5.1 brillnoether.lib

Library: brillnoether.lib

Purpose: Riemann-Roch spaces of divisors on curves

Authors: I. Stenger: stenger@mathematik.uni-kl.de
Janko Boehm boehm@mathematik.uni-kl.de

Procedures: See also: [Section D.10.1 \[brnoeth.lib\]](#), page 1926.

D.5.1.1 RiemannRochBN

Procedure from library `brillnoether.lib` (see [Section D.5.1 \[brillnoether.lib\]](#), page 1394).

Usage: RiemannRochBN(C,I,J); ideal C, ideal I, ideal J

Assume: C is a homogeneous ideal defining a projective curve. If C is a non-planar curve, then C is assumed to be nonsingular. This assumption is not checked.
The ideals I and J represent a divisor D on C.

Return: A vector space basis of the Riemann-Roch space of D, stored in a list `RRBasis`. The list `RRBasis` contains a list `IH` and a form `F`. The vector space basis of $L(D)$ consists of all rational functions G/F , where G is an element of `IH`.

Example:

```
LIB "brillnoether.lib";
ring R = 0,(x,y,z),dp;
poly f = y^2+x^2-1;
f = homog(f,z);
ideal C = f;
ideal P1 = x,y-z;
ideal P2 = x^2+y^2,z;
ideal I = intersect(P1^3,P2^2);
ideal P3 = x+z,y;
ideal J = P3^2;
RiemannRochBN(C,I,J);
⇒ [1]:
⇒   _[1]=65y2z2-81xz3-81z4
⇒   _[2]=65xyz2+63xz3+65yz3+63z4
⇒   _[3]=65y3z-81xyz2-81yz3
⇒   _[4]=65xy2z-81x2z2-81xz3
⇒   _[5]=65y4-81xy2z-81y2z2
⇒   _[6]=65xy3-81x2yz-81xyz2
⇒ [2]:
⇒   8xyz2-y2z2-8xz3+2yz3-z4
```

D.5.2 chern_lib

Library: chern.lib

Purpose: Symbolic Computations with Chern classes, Computation of Chern classes

Author: Oleksandr Iena, o.g.yena@gmail.com

Overview: A toolbox for symbolic computations with Chern classes. The Aluffi's algorithms for computation of characteristic classes of algebraic varieties (Segre, Fulton, Chern-Schwartz-MacPherson classes) are implemented as well.

References:

- [1] Aluffi, Paolo Computing characteristic classes of projective schemes. Journal of Symbolic Computation, 35 (2003), 3-19. Procedures:

D.5.2.1 symm

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\]](#), page 1395).

Usage: `symm(l [n]);` `l` a list of polynomials, `n` integer

Return: list of polynomials

Purpose: computes the list of elementary symmetric functions in the entries of `l`

Note: makes sense only for a list of polynomials

Example:

```
LIB "chern.lib";
// elementary symmetric functions in x, y, z:
ring r = 0, (x, y, z), dp;
list l=(x, y, z);
print(symm(l));
⇒ [1]:
⇒ x+y+z
⇒ [2]:
⇒ xy+xz+yz
⇒ [3]:
⇒ xyz
//now let us compute only the first two symmetric polynomials in a(1), ... , a(10)
ring q= 0,(a(1..10)), dp;
list l=a(1..10);
print(symm(l, 2));
⇒ [1]:
⇒ a(1)+a(2)+a(3)+a(4)+a(5)+a(6)+a(7)+a(8)+a(9)+a(10)
⇒ [2]:
⇒ a(1)*a(2)+a(1)*a(3)+a(2)*a(3)+a(1)*a(4)+a(2)*a(4)+a(3)*a(4)+a(1)*a(5)+\
a(2)*a(5)+a(3)*a(5)+a(4)*a(5)+a(1)*a(6)+a(2)*a(6)+a(3)*a(6)+a(4)*a(6)+a(5)\
)*a(6)+a(1)*a(7)+a(2)*a(7)+a(3)*a(7)+a(4)*a(7)+a(5)*a(7)+a(6)*a(7)+a(1)*a(
```

```
(8)+a(2)*a(8)+a(3)*a(8)+a(4)*a(8)+a(5)*a(8)+a(6)*a(8)+a(7)*a(8)+a(1)*a(9)\
+a(2)*a(9)+a(3)*a(9)+a(4)*a(9)+a(5)*a(9)+a(6)*a(9)+a(7)*a(9)+a(8)*a(9)+a(\
1)*a(10)+a(2)*a(10)+a(3)*a(10)+a(4)*a(10)+a(5)*a(10)+a(6)*a(10)+a(7)*a(10\
)+a(8)*a(10)+a(9)*a(10)
```

D.5.2.2 symNsym

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `symNsym(f, c);` `f` polynomial; `c` list of polynomials

Return: list with 2 poly entries

Purpose: computes a symmetric and a non-symmetric part of `f` in terms of the elementary symmetric functions from `c` as well a non-symmetric remainder

Note: constants are considered symmetric

Example:

```
LIB "chern.lib";
ring r=0, (x,y,z, c(1..3)), dp;
list l=c(1..3);
// The symmetric part of f = 3x2 + 3y2 + 3z2 + 7xyz + y
// in terms of the elementary symmetric functions c(1), c(2), c(3)
// and the remainder
poly f = 3x2 + 3y2 + 3z2 + 7xyz + y;
print( symNsym(f, l) );
⇒ [1]:
⇒ 3*c(1)^2-6*c(2)+7*c(3)
⇒ [2]:
⇒ y
// Take a symmetric polynomial in variables x and z
f=x2+xz+z2;
// Express it in terms of the elementary the symmetric functions
print( symNsym(f, l)[1]);
⇒ c(1)^2-c(2)
```

D.5.2.3 CompleteHomog

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `CompleteHomog(N, c);` `N` integer, `c` list of polynomials

Return: list of polynomials

Purpose: computes the list of the complete homogeneous symmetric polynomials in terms of the elementary symmetric polynomials (entries of `c`)

Note:

Example:

```
LIB "chern.lib";
ring r = 0, (x(1..3)), dp;
list l=x(1..3);
//Complete homogeneous symmetric polynomials up to degree 3 in variables x(1), x(2),
print( CompleteHomog(3, l) );
```

```

⇒ [1]:
⇒ 1
⇒ [2]:
⇒ x(1)
⇒ [3]:
⇒ x(1)^2-x(2)
⇒ [4]:
⇒ x(1)^3-2*x(1)*x(2)+x(3)

```

D.5.2.4 segre

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `segre(c[, N]);` c list of polynomials, N integer

Return: list of polynomials

Purpose: computes the list of the Segre classes up to degree N in terms of the Chern classes from c

Note:

Example:

```

LIB "chern.lib";
ring r = 0, (c(1..3)), dp;
list l=c(1..3);
//Segre classes up to degree 5 in Chern classes c(1), c(2), c(3)
print( segre(l, 5) );
⇒ [1]:
⇒ -c(1)
⇒ [2]:
⇒ c(1)^2-c(2)
⇒ [3]:
⇒ -c(1)^3+2*c(1)*c(2)-c(3)
⇒ [4]:
⇒ c(1)^4-3*c(1)^2*c(2)+c(2)^2+2*c(1)*c(3)
⇒ [5]:
⇒ -c(1)^5+4*c(1)^3*c(2)-3*c(1)*c(2)^2-3*c(1)^2*c(3)+2*c(2)*c(3)

```

D.5.2.5 chern

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chern(s);` s list of polynomials

Return: list of polynomials

Purpose: computes the list of the Chern classes up to degree N in terms of the Segre classes from s

Note:

Example:

```

LIB "chern.lib";
ring r = 0, (s(1..3)), dp;
list l=s(1..3);
// Chern classes in Segre classes s(1), s(2), s(3)

```

```

print( chern(1) );
⇒ [1]:
⇒ -s(1)
⇒ [2]:
⇒ s(1)^2-s(2)
⇒ [3]:
⇒ -s(1)^3+2*s(1)*s(2)-s(3)
// This procedure is inverse to segre(...). Indeed:
print( segre(chern(1), 3) );
⇒ [1]:
⇒ s(1)
⇒ [2]:
⇒ s(2)
⇒ [3]:
⇒ s(3)

```

D.5.2.6 chNum

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\]](#), page 1395).

Usage: `chNum(N, c);` N integer, c list

Return: list

Purpose: computes the Chern numbers of a vector bundle with Chern classes c on a complex manifold (variety) of dimension N,
the zeroes corresponding to the higher zero Chern classes are ignored

Note: computes basically the partitions of N
in summands not greater than the length of c

Example:

```

LIB "chern.lib";
ring r = 0, (c(1..2)), dp;
list l=c(1..2);
// Let c(1) be a variable of degree 1, let c(2) be a variable of degree 2.
// The monomials in c(1) and c(2) of weighted degree 5 are:
print( chNum( 5, l ) );
⇒ [1]:
⇒ c(1)^5
⇒ [2]:
⇒ c(1)^3*c(2)
⇒ [3]:
⇒ c(1)*c(2)^2
// Compare the result to the output of chNumbers(...):
print( chNumbers(5, l) );
⇒ [1]:
⇒ c(1)^5
⇒ [2]:
⇒ c(1)^3*c(2)
⇒ [3]:
⇒ c(1)*c(2)^2
⇒ [4]:
⇒ 0
⇒ [5]:

```

```

⇒      0
⇒ [6]:
⇒      0
⇒ [7]:
⇒      0

```

D.5.2.7 chNumbers

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chNumbers(r, c)`; `r` integer, `c` list

Return: list

Purpose: computes the Chern numbers of a vector bundle with Chern classes `c` on a complex manifold (variety) of dimension `r`

Note: computes basically the partitions of `r`

Example:

```

LIB "chern.lib";
ring r = 0, (c(1..3)), dp;
list l=c(1..3);
// The Chern numbers of a vector bundle with Chern classes c(1), c(2), c(3)
// on a 3-fold:
print( chNumbers( 3, l ) );
⇒ [1]:
⇒      c(1)^3
⇒ [2]:
⇒      c(1)*c(2)
⇒ [3]:
⇒      c(3)
// If the highest Chern class is zero, the Chern numbers are:
l=c(1..2);
print( chNumbers( 3, l ) );
⇒ [1]:
⇒      c(1)^3
⇒ [2]:
⇒      c(1)*c(2)
⇒ [3]:
⇒      0
// Compare this to the output of chNum(...):
print( chNum( 3, l ) );
⇒ [1]:
⇒      c(1)^3
⇒ [2]:
⇒      c(1)*c(2)

```

D.5.2.8 sum_of_powers

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `sum_of_powers(k, l)`; `k` non-negative integer, `l` list of polynomials

Return: polynomial

Purpose: computes the sum of `k`-th powers of the entries of `l`

Note: returns 0 if k is negative

Example:

```
LIB "chern.lib";
ring r = 0, (x, y, z), dp;
list l=x, y, z;
//sum of 7-th powers of x, y, z
print( sum_of_powers(7, l) );
⇨ x7+y7+z7
```

D.5.2.9 powSumSym

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `powSumSym(l [,N]);` l a list of polynomials, N integer

Return: list of polynomials

Purpose: computes the expressions for the sums of powers [up to degree N] in terms of the elementary symmetric polynomials (entries of l),

Note: returns the terms of the Chern character multiplied by the corresponding factorials

Example:

```
LIB "chern.lib";
// the expressions of the first 3 sums of powers of 3 variables a(1), a(2), a(3)
// in terms of the elementary symmetric polynomials c(1), c(2), c(3):
ring r = 0, (c(1..3)), dp;
list l=(c(1..3));
print(powSumSym(l));
⇨ [1]:
⇨ c(1)
⇨ [2]:
⇨ c(1)^2-2*c(2)
⇨ [3]:
⇨ c(1)^3-3*c(1)*c(2)+3*c(3)
// The first 5 sums in the same situation
print(powSumSym(l, 5));
⇨ [1]:
⇨ c(1)
⇨ [2]:
⇨ c(1)^2-2*c(2)
⇨ [3]:
⇨ c(1)^3-3*c(1)*c(2)+3*c(3)
⇨ [4]:
⇨ c(1)^4-4*c(1)^2*c(2)+2*c(2)^2+4*c(1)*c(3)
⇨ [5]:
⇨ c(1)^5-5*c(1)^3*c(2)+5*c(1)*c(2)^2+5*c(1)^2*c(3)-5*c(2)*c(3)
```

D.5.2.10 chAll

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chAll(l [,N]);` l a list of polynomials, N integer

Return: list of polynomials

Purpose: computes the list of terms of positive degree [up to degree N] of the Chern character, where the entries of `l` are considered as the Chern classes

Note: makes sense only for a list of polynomials

Example:

```
LIB "chern.lib";
// Chern character (terms of degree 1, 2, 3)
// corresponding to the Chern classes c(1), c(2), c(3):
ring r = 0, (c(1..3)), dp;
list l=(c(1..3));
print(chAll(l));
↳ [1]:
↳ c(1)
↳ [2]:
↳ 1/2*c(1)^2-c(2)
↳ [3]:
↳ 1/6*c(1)^3-1/2*c(1)*c(2)+1/2*c(3)
// terms up to degree 5 in the same situation
print(chAll(l, 5));
↳ [1]:
↳ c(1)
↳ [2]:
↳ 1/2*c(1)^2-c(2)
↳ [3]:
↳ 1/6*c(1)^3-1/2*c(1)*c(2)+1/2*c(3)
↳ [4]:
↳ 1/24*c(1)^4-1/6*c(1)^2*c(2)+1/12*c(2)^2+1/6*c(1)*c(3)
↳ [5]:
↳ 1/120*c(1)^5-1/24*c(1)^3*c(2)+1/24*c(1)*c(2)^2+1/24*c(1)^2*c(3)-1/24*c(2)*c(3)
```

D.5.2.11 chAllInv

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\]](#), page 1395).

Usage: `chAllInv(l)`; `l` a list of polynomials

Return: list of polynomials

Purpose: procedure inverse to `chAll()`, computes the list of Chern classes from the list of terms of positive degree of the Chern character

Note: makes sense only for a list of polynomials

Example:

```
LIB "chern.lib";
// first 3 Chern classes in terms of the first 3 terms
// of the Chern character Chern ch(1), ch(2), ch(3):
ring r = 0, (ch(1..3)), dp;
list l=(ch(1..3));
print(chAllInv(l));
↳ [1]:
↳ ch(1)
↳ [2]:
↳ 1/2*ch(1)^2-ch(2)
```

```

⇒ [3]:
⇒      1/6*ch(1)^3-ch(1)*ch(2)+2*ch(3)
// let's see that chAllInv() is inverse to chAll()
print( chAll( chAllInv(1) ) );
⇒ [1]:
⇒      ch(1)
⇒ [2]:
⇒      ch(2)
⇒ [3]:
⇒      ch(3)

```

D.5.2.12 chHE

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chHE(c)`; `c` list of polynomials

Return: polynomial

Purpose: computes the highest relevant term of the Chern character

Note: uses the elimination and is extremely inefficient,
is included just for comparison with `chAll(c)`

Example:

```

LIB "chern.lib";
ring r = 0, (c(1..3)), dp;
list l=c(1..3);
//the third degree term of the Chern character
print( chHE(l) );
⇒ 1/6*c(1)^3-1/2*c(1)*c(2)+1/2*c(3)

```

D.5.2.13 ChernRootsSum

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `ChernRootsSum(a, b)`; `a, b` lists of polynomials

Return: list of polynomials

Purpose: computes the Chern roots of the direct (Whitney) sum of a vector bundle with Chern roots `a` and a vector bundle with Chern roots `b`

Note:

Example:

```

LIB "chern.lib";
ring r = 0, (a(1..3), b(1..2)), dp;
// assume a(1), a(2), a(3) are the Chern roots of a vector bundle E
// assume b(1), b(2) are the Chern roots of a vector bundle F
list l=a(1..3);
list L=b(1..2);
// the Chern roots of their direct sum is
print( ChernRootsSum(l, L) );
⇒ [1]:
⇒      a(1)
⇒ [2]:

```

```

⇒      a(2)
⇒ [3] :
⇒      a(3)
⇒ [4] :
⇒      b(1)
⇒ [5] :
⇒      b(2)

```

D.5.2.14 chSum

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chSum(c, C);` `c, C` lists of polynomials

Return: list of polynomials

Purpose: computes the Chern classes of a direct sum of two vector bundles

Note:

Example:

```

LIB "chern.lib";
ring r = 0, (c(1..3), C(1..2)), dp;
// Let E be a vector bundle with Chern classes c(1), c(2), c(3).
// Let F be a vector bundle with Chern classes C(1), C(2).
list l=c(1..3);
list L=C(1..2);
// Then the Chern classes of their direct sum are
print( chSum(l, L) );
⇒ [1] :
⇒      c(1)+C(1)
⇒ [2] :
⇒      c(1)*C(1)+c(2)+C(2)
⇒ [3] :
⇒      c(2)*C(1)+c(1)*C(2)+c(3)
⇒ [4] :
⇒      c(3)*C(1)+c(2)*C(2)
⇒ [5] :
⇒      c(3)*C(2)

```

D.5.2.15 ChernRootsDual

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `ChernRootsDual(l);` `l` a list of polynomials

Return: list of polynomials

Purpose: computes the Chern roots of the dual vector bundle
of a vector bundle with Chern roots from `l`

Note:

Example:

```

LIB "chern.lib";
ring r = 0, (a(1..3)), dp;
// assume a(1), a(2), a(3) are the Chern roots of a vector bundle

```

```

list l=a(1..3);
// the Chern roots of the dual vector bundle
print( ChernRootsDual(l) );
⇒ [1]:
⇒   -a(1)
⇒ [2]:
⇒   -a(2)
⇒ [3]:
⇒   -a(3)

```

D.5.2.16 chDual

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chDual(c)`; `c` list of polynomials

Return: list of polynomials

Purpose: computes the list of Chern classes of the dual vector bundle

Note:

Example:

```

LIB "chern.lib";
// Chern classes of a vector bundle that is dual to a vector bundle
// with Chern classes c(1), c(2), c(3)
ring r=0, (c(1..3)), dp;
list l=c(1..3);
print(chDual(l));
⇒ [1]:
⇒   -c(1)
⇒ [2]:
⇒    c(2)
⇒ [3]:
⇒   -c(3)

```

D.5.2.17 ChernRootsProd

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `ChernRootsProd(a, b)`; `a, b` lists of polynomials

Return: list of polynomials

Purpose: computes the Chern roots of the tensor product of a vector bundle with Chern roots `a` and a vector bundles with Chern roots `b`

Note:

Example:

```

LIB "chern.lib";
ring r=0, (a(1..2), b(1..3)), dp;
list l=a(1..2);
list L=b(1..3);
// Chern roots of the tensor product of a vector bundle with Chern roots a(1), a(2)
// and a vector bundle with Chern roots b(1), b(2), b(3)
print(ChernRootsProd(l, L));

```

```

⇒ [1]:
⇒   a(1)+b(1)
⇒ [2]:
⇒   a(1)+b(2)
⇒ [3]:
⇒   a(1)+b(3)
⇒ [4]:
⇒   a(2)+b(1)
⇒ [5]:
⇒   a(2)+b(2)
⇒ [6]:
⇒   a(2)+b(3)

```

D.5.2.18 chProd

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chProd(r, c, R, C [, N]);` `r, R` polynomials (integers); `c, C` lists of polynomials, `N` integer

Return: list of polynomials

Purpose: computes the list of Chern classes of the product of two vector bundles in terms of their ranks and Chern classes [up to degree `N`]

Note:

Example:

```

LIB "chern.lib";
ring H = 0, ( r, R, c(1..3), C(1..2) ), dp;
list l=c(1..3);
list L=C(1..2);
// the Chern classes of the tensor product of a vector bundle E of rank 3
// with Chern classes c(1), c(2), c(3)
// and a vector bundle F of rank 2 with Chern classes C(1) and C(2):
print( chProd(3, l, 2, L) );
⇒ [1]:
⇒   2*c(1)+3*C(1)
⇒ [2]:
⇒   c(1)^2+5*c(1)*C(1)+3*C(1)^2+2*c(2)+3*C(2)
⇒ [3]:
⇒   2*c(1)^2*C(1)+4*c(1)*C(1)^2+C(1)^3+2*c(1)*c(2)+4*c(2)*C(1)+4*c(1)*C(2)\
+6*C(1)*C(2)+2*c(3)
⇒ [4]:
⇒   c(1)^2*C(1)^2+c(1)*C(1)^3+3*c(1)*c(2)*C(1)+3*c(2)*C(1)^2+2*c(1)^2*C(2)\
+6*c(1)*C(1)*C(2)+3*C(1)^2*C(2)+c(2)^2+2*c(1)*c(3)+3*c(3)*C(1)+3*C(2)^2
⇒ [5]:
⇒   c(1)*c(2)*C(1)^2+c(2)*C(1)^3+2*c(1)^2*C(1)*C(2)+2*c(1)*C(1)^2*C(2)+c(2)\
)^2*C(1)+2*c(1)*c(3)*C(1)+3*c(3)*C(1)^2+2*c(1)*c(2)*C(2)+2*c(1)*C(2)^2+3*\
C(1)*C(2)^2+2*c(2)*c(3)-6*c(3)*C(2)
⇒ [6]:
⇒   c(1)*c(3)*C(1)^2+c(3)*C(1)^3+c(1)*c(2)*C(1)*C(2)+c(2)*C(1)^2*C(2)+c(1)\
^2*C(2)^2+c(1)*C(1)*C(2)^2+c(2)*c(3)*C(1)+c(2)^2*C(2)-2*c(1)*c(3)*C(2)-3*\
c(3)*C(1)*C(2)-2*c(2)*C(2)^2+C(2)^3+c(3)^2
// the first two Chern classes of the tensor product
// of a vector bundle E of rank r with Chern classes c(1) and c(2)

```

```
// and a vector bundle G of rank R with Chern classes C(1) and C(2)
// this gives the Chern classes of a tensor product on a complex surface
l=c(1..2);
L=C(1..2);
print( chProd(r, l, R, L, 2 ) );
⇒ [1]:
⇒ R*c(1)+r*C(1)
⇒ [2]:
⇒ 1/2*R^2*c(1)^2+r*R*c(1)*C(1)+1/2*r^2*C(1)^2-1/2*R*c(1)^2-1/2*r*C(1)^2+
R*c(2)-c(1)*C(1)+r*C(2)
```

D.5.2.19 chProdE

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\]](#), page 1395).

Usage: `chProdE(c, C)`; `c, C` lists of polynomials

Return: list of polynomials

Purpose: computes the list of Chern classes of the product of two vector bundles in terms of their Chern classes

Note: makes sense only for (lists of) polynomials;
uses elimination, hence very inefficient;
included only for comparison with `chProd(...)`

Example:

```
LIB "chern.lib";
ring H = 0, ( c(1..3), C(1..2) ), dp;
list l=c(1..3);
list L=C(1..2);
// the Chern classes of the tensor product of a vector bundle E of rank 3
// with Chern classes c(1), c(2), c(3)
// and a vector bundle F of rank 2 with Chern classes C(1) and C(2):
print( chProdE(l, L) );
⇒ [1]:
⇒ 2*c(1)+3*C(1)
⇒ [2]:
⇒ c(1)^2+5*c(1)*C(1)+3*C(1)^2+2*c(2)+3*C(2)
⇒ [3]:
⇒ 2*c(1)^2*C(1)+4*c(1)*C(1)^2+C(1)^3+2*c(1)*c(2)+4*c(2)*C(1)+4*c(1)*C(2)\
+6*C(1)*C(2)+2*c(3)
⇒ [4]:
⇒ c(1)^2*C(1)^2+c(1)*C(1)^3+3*c(1)*c(2)*C(1)+3*c(2)*C(1)^2+2*c(1)^2*C(2)\
+6*c(1)*C(1)*C(2)+3*C(1)^2*C(2)+c(2)^2+2*c(1)*c(3)+3*c(3)*C(1)+3*C(2)^2
⇒ [5]:
⇒ c(1)*c(2)*C(1)^2+c(2)*C(1)^3+2*c(1)^2*C(1)*C(2)+2*c(1)*C(1)^2*C(2)+c(2)\
)^2*C(1)+2*c(1)*c(3)*C(1)+3*c(3)*C(1)^2+2*c(1)*c(2)*C(2)+2*c(1)*C(2)^2+3*\
C(1)*C(2)^2+2*c(2)*c(3)-6*c(3)*C(2)
⇒ [6]:
⇒ c(1)*c(3)*C(1)^2+c(3)*C(1)^3+c(1)*c(2)*C(1)*C(2)+c(2)*C(1)^2*C(2)+c(1)\
^2*C(2)^2+c(1)*C(1)*C(2)^2+c(2)*c(3)*C(1)+c(2)^2*C(2)-2*c(1)*c(3)*C(2)-3*\
c(3)*C(1)*C(2)-2*c(2)*C(2)^2+C(2)^3+c(3)^2
```

D.5.2.20 chProdL

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chProdL(r, c, R, C);` r, R integers; c, C lists of polynomials

Return: list

Purpose: computes the list of Chern classes of the product of two vector bundles in terms of their Chern classes

Note: Implementation of the formula of Lascoux, the Schur polynomials are computed using the second Jacobi-Trudi formula (in terms of the Chern classes)

Example:

```
LIB "chern.lib";
// The Chern classes of the tensor product of a vector bundle of rank 3
// with Chern classes c(1), c(2), c(3) and a vector bundle of rank 1 with
// Chern class C(1)
ring r = 0, ( c(1..3), C(1)), dp;
list c=c(1..3);
list C=C(1);
print( chProdL(3,c,1,C) );
⇒ [1]:
⇒ c(1)+3*C(1)
⇒ [2]:
⇒ 2*c(1)*C(1)+3*C(1)^2+c(2)
⇒ [3]:
⇒ c(1)*C(1)^2+C(1)^3+c(2)*C(1)+c(3)
```

D.5.2.21 chProdLP

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chProdLP(r, c, R, C);` r, R integers; c, C lists of polynomials

Return: polynomial

Purpose: computes the total Chern class of the product of two vector bundles in terms of their ranks and Chern classes

Note: Implementation of the formula of Lascoux, the Schur polynomials are computed using the second Jacobi-Trudi formula (in terms of the Chern classes)

Example:

```
LIB "chern.lib";
// The total Chern class of the tensor product of a vector bundle of rank 3
// with Chern classes c(1), c(2), c(3) and a vector bundle of rank 1 with
// Chern class C(1)
ring r = 0, ( c(1..3), C(1)), ws(1,2,3, 1);
list c=c(1..3);
list C=C(1);
print( chProdLP(3,c,1,C) );
⇒ 1+c(1)+3*C(1)+c(2)+2*c(1)*C(1)+3*C(1)^2+c(3)+c(2)*C(1)+c(1)*C(1)^2+C(1)^3
```

D.5.2.22 chProdM

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chProdM(r, c, R, C)`; r, R integers; c, C lists of polynomials

Return: list

Purpose: computes the list of Chern classes of the product of two vector bundles in terms of their Chern classes

Note: Implementation of the formula of Manivel

Example:

```
LIB "chern.lib";
// The Chern classes of the tensor product of a vector bundle of rank 3
// with Chern classes c(1), c(2), c(3) and a vector bundle of rank 1 with
// Chern class C(1)
ring r = 0, ( c(1..3), C(1)), dp;
list c=c(1..3);
list C=C(1);
print( chProdM(3,c,1,C) );
⇒ [1]:
⇒ c(1)+3*C(1)
⇒ [2]:
⇒ 2*c(1)*C(1)+3*C(1)^2+c(2)
⇒ [3]:
⇒ c(1)*C(1)^2+C(1)^3+c(2)*C(1)+c(3)
```

D.5.2.23 chProdMP

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chProdMP(r, c, R, C)`; r, R integers; c, C lists of polynomials

Return: polynomial

Purpose: computes the total Chern class of the product of two vector bundles in terms of their ranks and Chern classes

Note: Implementation of the formula of Lascoux, the Schur polynomials are computed using the second Jacobi-Trudi formula (in terms of the Chern classes)

Example:

```
LIB "chern.lib";
// The total Chern class of the tensor product of a vector bundle of rank 3
// with Chern classes c(1), c(2), c(3) and a vector bundle of rank 1 with
// Chern class C(1)
ring r = 0, ( c(1..3), C(1)), ws(1,2,3, 1);
list c=c(1..3);
list C=C(1);
print( chProdMP(3,c,1,C) );
⇒ 1+c(1)+3*C(1)+c(2)+2*c(1)*C(1)+3*C(1)^2+c(3)+c(2)*C(1)+c(1)*C(1)^2+C(1)^3
```

D.5.2.24 ChernRootsHom

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `ChernRootsHom(a, b)`; `a, b` lists of polynomials

Return: list of polynomials

Purpose: for a vector bundle E with Chern roots a and a vector bundle F with Chern roots b , computes the Chern roots of $\text{Hom}(E, F)$

Note:

Example:

```
LIB "chern.lib";
ring r=0, (a(1..2), b(1..3)), dp;
list l=a(1..2);
list L=b(1..3);
// Let E be a vector bundle with Chern roots a(1), a(2),
// let F be a vector bundle with Chern roots b(1), b(2), b(3).
// Then the Chern roots of Hom(E, F) are
print(ChernRootsHom(l, L));
⇒ [1]:
⇒ -a(1)+b(1)
⇒ [2]:
⇒ -a(1)+b(2)
⇒ [3]:
⇒ -a(1)+b(3)
⇒ [4]:
⇒ -a(2)+b(1)
⇒ [5]:
⇒ -a(2)+b(2)
⇒ [6]:
⇒ -a(2)+b(3)
```

D.5.2.25 chHom

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chHom(r, c, R, C [, N])`; `r, R` polynomials (integers); `c, C` lists of polynomials, `N` integer

Return: list of polynomials

Purpose: computes [up to degree N] the list of Chern classes of the vector bundle $\text{Hom}(E, F)$ in terms of the ranks and the Chern classes of E and F

Note:

Example:

```
LIB "chern.lib";
ring H = 0, ( r, R, c(1..3), C(1..2) ), dp;
list l=c(1..3);
list L=C(1..2);
// the Chern classes of Hom(E, F) for a vector bundle E of rank 3
// with Chern classes c(1), c(2), c(3)
// and a vector bundle F of rank 2 with Chern classes C(1) and C(2):
print( chHom(3, l, 2, L) );
⇒ [1]:
```

```

⇒      -2*c(1)+3*C(1)
⇒ [2]:
⇒      c(1)^2-5*c(1)*C(1)+3*C(1)^2+2*c(2)+3*C(2)
⇒ [3]:
⇒      2*c(1)^2*C(1)-4*c(1)*C(1)^2+C(1)^3-2*c(1)*c(2)+4*c(2)*C(1)-4*c(1)*C(2)\
      +6*C(1)*C(2)-2*c(3)
⇒ [4]:
⇒      c(1)^2*C(1)^2-c(1)*C(1)^3-3*c(1)*c(2)*C(1)+3*c(2)*C(1)^2+2*c(1)^2*C(2)\
      -6*c(1)*C(1)*C(2)+3*C(1)^2*C(2)+c(2)^2+2*c(1)*c(3)-3*c(3)*C(1)+3*C(2)^2
⇒ [5]:
⇒      -c(1)*c(2)*C(1)^2+c(2)*C(1)^3+2*c(1)^2*C(1)*C(2)-2*c(1)*C(1)^2*C(2)+c(\
      2)^2*C(1)+2*c(1)*c(3)*C(1)-3*c(3)*C(1)^2-2*c(1)*c(2)*C(2)-2*c(1)*C(2)^2+3\
      *C(1)*C(2)^2-2*c(2)*c(3)+6*c(3)*C(2)
⇒ [6]:
⇒      c(1)*c(3)*C(1)^2-c(3)*C(1)^3-c(1)*c(2)*C(1)*C(2)+c(2)*C(1)^2*C(2)+c(1)\
      ^2*C(2)^2-c(1)*C(1)*C(2)^2-c(2)*c(3)*C(1)+c(2)^2*C(2)-2*c(1)*c(3)*C(2)+3*\

      R*c(2)+c(1)*C(1)+r*C(2)

```

D.5.2.26 ChernRootsSymm

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\]](#), page 1395).

Usage: ChernRootsSymm(m, l); m integer, l a list of polynomials

Return: list of polynomials

Purpose: computes the Chern roots of m-th symmetric power
of a vector bundle with Chern roots from l

Note:

Example:

```

LIB "chern.lib";
ring r=0, (a(1..3)), dp;
list l=a(1..3);
// the Chern roots of the second symmetric power of a vector bundle
// with Chern roots a(1), a(2), a(3)
print( ChernRootsSymm(2, l) );
⇒ [1]:
⇒      2*a(1)
⇒ [2]:
⇒      a(1)+a(2)
⇒ [3]:

```

```

⇒      a(1)+a(3)
⇒ [4] :
⇒      2*a(2)
⇒ [5] :
⇒      a(2)+a(3)
⇒ [6] :
⇒      2*a(3)

```

D.5.2.27 ChernRootsWedge

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: ChernRootsWedge(m, l); m integer, l a list of polynomials

Return: list of polynomials

Purpose: computes the Chern roots of m-th exterior power of a vector bundle with Chern roots from l

Note: makes sense only for list of polynomials

Example:

```

LIB "chern.lib";
ring r=0, (a(1..3)), dp;
list l=a(1..3);
// the Chern roots of the second exterior power of a vector bundle
// with Chern roots a(1), a(2), a(3)
print( ChernRootsWedge(2, l) );
⇒ [1] :
⇒      a(2)+a(3)
⇒ [2] :
⇒      a(1)+a(3)
⇒ [3] :
⇒      a(1)+a(2)

```

D.5.2.28 chSymm

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: chSymm(k, r, c[, pos]); k, r integers, c list of polynomials, pos list of integers

Return: list with entries: int N, list of polynomials l

Purpose: computes the rank and the Chern classes of the symmetric power of a vector bundle

Note: for the second symmetric power `chSymm2L(...)` could be faster

Example:

```

LIB "chern.lib";
ring r=0, (c(1..5)), dp;
list l=c(1..5);
// the rank and the Chern classes of the second symmetric power of a vector bundle of
print( chSymm(2, 3, l) );
⇒ [1] :
⇒      6
⇒ [2] :
⇒      [1] :

```

```

⇒      4*c(1)
⇒      [2]:
⇒      5*c(1)^2+5*c(2)
⇒      [3]:
⇒      2*c(1)^3+11*c(1)*c(2)+7*c(3)
⇒      [4]:
⇒      6*c(1)^2*c(2)+4*c(2)^2+14*c(1)*c(3)
⇒      [5]:
⇒      4*c(1)*c(2)^2+8*c(1)^2*c(3)+4*c(2)*c(3)
⇒      [6]:
⇒      8*c(1)*c(2)*c(3)-8*c(3)^2
// the rank and the first 3 Chern classes
// of the second symmetric power of a vector bundle of rank 5
print( chSymm(2, 5, 1, 1, 2, 3) );
⇒ [1]:
⇒      15
⇒ [2]:
⇒      [1]:
⇒      6*c(1)
⇒      [2]:
⇒      14*c(1)^2+7*c(2)
⇒      [3]:
⇒      16*c(1)^3+31*c(1)*c(2)+9*c(3)

```

D.5.2.29 chSymm2L

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\]](#), page 1395).

Usage: `chSymm2L(r, c);` `r` integer, `c` list of polynomials

Return: list of polynomials

Purpose: computes the Chern classes of the second symmetric power of a vector bundle

Note: Implementation of the formula of Lascoux, the Schur polynomials are computed using the second Jacobi-Trudi formula (in terms of the Chern classes)

Example:

```

LIB "chern.lib";
ring r=0, (c(1..2)), dp;
list l=c(1..2);
// the Chern classes of the second symmetric power of a vector bundle of rank 2
print( chSymm2L(2, l));
⇒ [1]:
⇒      3
⇒ [2]:
⇒      [1]:
⇒      3*c(1)
⇒      [2]:
⇒      2*c(1)^2+4*c(2)
⇒      [3]:
⇒      4*c(1)*c(2)

```

D.5.2.30 chSymm2LP

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\]](#), page 1395).

Usage: `chSymm2LP(r, c);` r integer, c list of polynomials

Return: poly

Purpose: computes the total Chern class of the second symmetric power of a vector bundle

Note: Implementation of the formula of Lascoux, the Schur polynomials are computed using the second Jacobi-Trudi formula (in terms of the Chern classes)

Example:

```
LIB "chern.lib";
ring r=0, (c(1..2)), ws(1, 2);
list l=c(1..2);
// the total Chern class of the second symmetric power of a vector bundle of rank 2
print( chSymm2LP(2, l));
⇒ 1+3*c(1)+2*c(1)^2+4*c(2)+4*c(1)*c(2)
```

D.5.2.31 chWedge

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chWedge(k, r, c [,pos]);` k, r integers, c list of polynomials, pos list of integers

Return: list with entries: int N, list of polynomials l

Purpose: computes the rank and the Chern classes of the exterior power of a vector bundle

Note: for the second exterior power `chWedge2L(...)` could be faster

Example:

```
LIB "chern.lib";
ring r=0, (c(1..5)), dp;
list l=c(1..5);
// the rank and the Chern classes of the second exterior power of a vector bundle of
print( chWedge(2, 3, l) );
⇒ [1]:
⇒ 3
⇒ [2]:
⇒ [1]:
⇒ 2*c(1)
⇒ [2]:
⇒ c(1)^2+c(2)
⇒ [3]:
⇒ c(1)*c(2)-c(3)
// the rank and the first 3 Chern classes
// of the fourth exterior power of a vector bundle of rank 5
print( chWedge(4, 5, l, 1, 2, 3) );
⇒ [1]:
⇒ 5
⇒ [2]:
⇒ [1]:
⇒ 4*c(1)
⇒ [2]:
⇒ 6*c(1)^2+c(2)
⇒ [3]:
⇒ 4*c(1)^3+3*c(1)*c(2)-c(3)
```

D.5.2.32 chWedge2L

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chWedge2L(r, c);` r integer, c list of polynomials

Return: list of polynomials

Purpose: computes the Chern classes of the second exterior power of a vector bundle

Note: Implementation of the formula of Lascoux, the Schur polynomials are computed using the second Jacobi-Trudi formula (in terms of the Chern classes)

Example:

```
LIB "chern.lib";
ring r=0, (c(1..3)), dp;
list l=c(1..3);
// the Chern classes of the second exterior power of a vector bundle of rank 3
print(chWedge2L(3, l));
⇒ [1]:
⇒ 3
⇒ [2]:
⇒ [1]:
⇒ 2*c(1)
⇒ [2]:
⇒ c(1)^2+c(2)
⇒ [3]:
⇒ c(1)*c(2)-c(3)
```

D.5.2.33 chWedge2LP

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chWedge2LP(r, c);` r integer, c list of polynomials

Return: poly

Purpose: computes the total Chern class of the second exterior power of a vector bundle

Note: Implementation of the formula of Lascoux, the Schur polynomials are computed using the second Jacobi-Trudi formula (in terms of the Chern classes)

Example:

```
LIB "chern.lib";
ring r=0, (c(1..3)), ws(1,2,3);
list l=c(1..3);
// the total Chern class of the second exterior power of a vector bundle of rank 3
print(chWedge2LP(3, l));
⇒ 1+2*c(1)+c(1)^2+c(2)+c(1)*c(2)-c(3)
```

D.5.2.34 todd

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `todd(l [, n]);` l a list of polynomials, n integer

Return: list of polynomials

Purpose: computes [the first n] terms of the Todd class

Note: returns an empty list if l is empty

Example:

```
LIB "chern.lib";
// the terms of the Todd class up to degree 5
// in terms of the Chern classes c(1), c(2), c(3), c(4), c(5)
ring r=0, (c(1..5)), dp;
list l=c(1..5);
print( todd( l ) );
⇒ [1]:
⇒ 1/2*c(1)
⇒ [2]:
⇒ 1/12*c(1)^2+1/12*c(2)
⇒ [3]:
⇒ 1/24*c(1)*c(2)
⇒ [4]:
⇒ -1/720*c(1)^4+1/180*c(1)^2*c(2)+1/240*c(2)^2+1/720*c(1)*c(3)-1/720*c(4\
)
⇒ [5]:
⇒ -1/1440*c(1)^3*c(2)+1/480*c(1)*c(2)^2+1/1440*c(1)^2*c(3)-1/1440*c(1)*c\
(4)
// in the same situation compute only first two terms
print( todd(l, 2) );
⇒ [1]:
⇒ 1/2*c(1)
⇒ [2]:
⇒ 1/12*c(1)^2+1/12*c(2)
// compute the first 5 terms corresponding to the Chern classes c(1), c(2)
l=c(1..2);
print( todd(l, 5) );
⇒ [1]:
⇒ 1/2*c(1)
⇒ [2]:
⇒ 1/12*c(1)^2+1/12*c(2)
⇒ [3]:
⇒ 1/24*c(1)*c(2)
⇒ [4]:
⇒ -1/720*c(1)^4+1/180*c(1)^2*c(2)+1/240*c(2)^2
⇒ [5]:
⇒ -1/1440*c(1)^3*c(2)+1/480*c(1)*c(2)^2
```

D.5.2.35 toddE

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\]](#), page 1395).

Usage: `toddE(l)`; l a list of polynomials

Return: polynomial

Purpose: computes the highest relevant term of the Todd class

Note: returns an empty list if l is empty,
very inefficient because the elimination is used, included for comparison with `todd(c)`

Example:

```

LIB "chern.lib";
// first 3 terms of the Todd class in terms of the Chern classes c(1), c(2), c(3)
ring r=0, (c(1..3)), dp;
list l;
//first term
l=c(1);
print( toddE( l ) );
 $\mapsto 1/2*c(1)$ 
// second term
l=c(1..2);
print( toddE( l ) );
 $\mapsto 1/12*c(1)^2+1/12*c(2)$ 
// third term
l=c(1..3);
print( toddE( l ) );
 $\mapsto 1/24*c(1)*c(2)$ 

```

D.5.2.36 Bern

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `Bern(n)`; n non-negative integer

Return: list of numbers

Purpose: computes the list of (second) Bernoulli numbers from $B(0)$ to $B(n)$

Note: needs a base ring to be defined, returns an empty list if n is negative, uses the Akiyama-Tanigawa algorithm

Example:

```

LIB "chern.lib";
// first 10 Bernoulli numbers: B(0), ..., B(9)
ring r=0,(t), dp;
print( Bern(9) );
 $\mapsto [1]:$ 
 $\mapsto 1$ 
 $\mapsto [2]:$ 
 $\mapsto 1/2$ 
 $\mapsto [3]:$ 
 $\mapsto 1/6$ 
 $\mapsto [4]:$ 
 $\mapsto 0$ 
 $\mapsto [5]:$ 
 $\mapsto -1/30$ 
 $\mapsto [6]:$ 
 $\mapsto 0$ 
 $\mapsto [7]:$ 
 $\mapsto 1/42$ 
 $\mapsto [8]:$ 
 $\mapsto 0$ 
 $\mapsto [9]:$ 
 $\mapsto -1/30$ 
 $\mapsto [10]:$ 
 $\mapsto 0$ 

```

D.5.2.37 tdCf

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `tdCf(n);` n integer

Return: list of rational numbers

Purpose: computes up to degree n the coefficients of the Todd class of a line bundle

Note:

Example:

```
LIB "chern.lib";
// first 5 coefficients
ring r=0,(t), dp;
print( tdCf(4) );
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 1/2
⇒ [3]:
⇒ 1/12
⇒ [4]:
⇒ 0
⇒ [5]:
⇒ -1/720
```

D.5.2.38 tdTerms

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `tdTerms(n, f);` n integer, f polynomial

Return: list of polynomials

Purpose: computes the terms of the Todd class of the line bundle with the Chern root f

Note:

Example:

```
LIB "chern.lib";
ring r=0, (t), ls;;
// the terms of the Todd class of a line bundle with Chern root t up to degree 4
print( tdTerms(4, t) );
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 1/2t
⇒ [3]:
⇒ 1/12t2
⇒ [4]:
⇒ 0
⇒ [5]:
⇒ -1/720t4
```

D.5.2.39 tdFactor

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `tdFactor(n, a)`; n integer, a polynomial

Return: polynomial

Purpose: computes up to degree n the Todd class of the line bundle corresponding to the Chern root t

Note: returns 0 if n is negative

Example:

```
LIB "chern.lib";
// the Todd class up to degree 4
ring r=0,(t), ls;
print( tdFactor(4, t) );
↪ 1+1/2t+1/12t2-1/720t4
```

D.5.2.40 cProj

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `cProj(n)`; n integer

Return: list of integers

Purpose: computes the terms of positive degree of the total Chern class of the tangent bundle on the complex projective space

Note:

Example:

```
LIB "chern.lib";
ring r=0, (t), dp;
// the coefficients of the total Chern class of the complex projective line
print( cProj(1) );
↪ [1]:
↪ 2
// the coefficients of the total Chern class of the complex projective plane
print( cProj(2) );
↪ [1]:
↪ 3
↪ [2]:
↪ 3
// the coefficients of the total Chern class of the complex projective space
// of dimension three
print( cProj(3) );
↪ [1]:
↪ 4
↪ [2]:
↪ 6
↪ [3]:
↪ 4
```

D.5.2.41 chProj

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chProj(n)`; n integer

Return: list of (rational) numbers

Purpose: computes the terms of the Chern character of the tangent bundle on the complex projective space

Note:

Example:

```
LIB "chern.lib";
ring r=0, (t), dp;
// the coefficients of the Chern character of the complex projective line
print( chProj(1) );
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 2
// the coefficients of the Chern character of the complex projective plane
print( chProj(2) );
⇒ [1]:
⇒ 2
⇒ [2]:
⇒ 3
⇒ [3]:
⇒ 3/2
// the coefficients of the Chern character of the complex 3-dimensional projective space
print( chProj(3) );
⇒ [1]:
⇒ 3
⇒ [2]:
⇒ 4
⇒ [3]:
⇒ 2
⇒ [4]:
⇒ 2/3
```

D.5.2.42 tdProj

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `tdProj(n)`; n integer

Return: list of (rational) numbers

Purpose: computes the terms of the Todd class
of the (tangent bundle of the) complex projective space

Note:

Example:

```
LIB "chern.lib";
ring r=0, (t), dp;
// the coefficients of the Todd class of the complex projective line
```

```

print( tdProj(1) );
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 1
// the coefficients of the Todd class of the complex projective line
print( tdProj(2) );
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 3/2
⇒ [3]:
⇒ 1
// the coefficients of the Todd class of the complex projective line
print( tdProj(3) );
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 2
⇒ [3]:
⇒ 11/6
⇒ [4]:
⇒ 1

```

D.5.2.43 eulerChProj

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\]](#), page 1395).

Usage: `eulerChProj(n, r, c)`; `n` integer, `r` polynomial (or integer), `c` list of polynomials

Return: polynomial

Purpose: computes the Euler characteristic of a vector bundle on P_n in terms of its rank and Chern classes

Note:

Example:

```

LIB "chern.lib";
ring h=0, (r, c(1..3)), ws(0,1,2,3);
list l=c(1..3);
// the Euler characteristic of a vector bundle on the projective line
print( eulerChProj(1, r, l) );
⇒ r+c(1)
// the Euler characteristic of a vector bundle on the projective plane
print( eulerChProj(2, r, l) );
⇒ r+3/2*c(1)+1/2*c(1)^2-c(2)
// the Euler characteristic of a vector bundle on P_3
print( eulerChProj(3, r, l) );
⇒ r+11/6*c(1)+c(1)^2-2*c(2)+1/6*c(1)^3-1/2*c(1)*c(2)+1/2*c(3)
// assume now that we have a bundle framed at a subplane of P_3
// this implies c(1)=c(2)=0
l= 0, 0, c(3);
// the Euler characteristic is
print( eulerChProj(3, r, l) );

```

```

    ↪ r+1/2*c(3)
    // which implies that c(3) must be even in this case

```

D.5.2.44 chNumbersProj

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chNumbersProj(n)`; n integer

Return: list of integers

Purpose: computes the Chern numbers of the projective space P_n

Note:

Example:

```

LIB "chern.lib";
ring h=0, (t), dp;
// The Chern numbers of the projective plane P_2:
print( chNumbersProj(2) );
↪ [1]:
↪ 9
↪ [2]:
↪ 3
// The Chern numbers of P_3:
print( chNumbersProj(3) );
↪ [1]:
↪ 64
↪ [2]:
↪ 24
↪ [3]:
↪ 4

```

D.5.2.45 classpoly

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `classpoly(l, t)`; l list of polynomials, t polynomial

Return: polynomial

Purpose: computes the polynomial in t with coefficients being the entries of l

Note:

Example:

```

LIB "chern.lib";
ring r=0, (c(1..5), t), ds;
list l=c(1..5);
// get the polynomial c(1)*t + c(2)*t^2 + ... + c(5)*t^5
print( classpoly(l, t) );
↪ c(1)*t+c(2)*t^2+c(3)*t^3+c(4)*t^4+c(5)*t^5

```

D.5.2.46 chernPoly

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chernPoly(c, t)`; c list of polynomials, t polynomial

Return: polynomial

Purpose: computes the Chern polynomial in t

Note: does the same as `toddPoly(...)`

Example:

```
LIB "chern.lib";
ring r=0, (c(1..5), t), ds;
list l=c(1..5);
// get the Chern polynomial 1 + c(1)*t + c(2)*t^2 + ... + c(5)*t^5
print( chernPoly(l, t) );
↪ 1+c(1)*t+c(2)*t^2+c(3)*t^3+c(4)*t^4+c(5)*t^5
```

D.5.2.47 chernCharPoly

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `chernCharPoly(r, ch, t)`; r polynomial, ch list of polynomials, t polynomial

Return: polynomial

Purpose: computes the polynomial in t corresponding to the Chern character

Note:

Example:

```
LIB "chern.lib";
ring h=0, (r, ch(1..5), t), ds;
list l=ch(1..5);
// get the polynomial r + ch(1)*t + ch(2)*t^2 + ... + ch(5)*t^5
print( chernCharPoly(r, l, t) );
↪ r+ch(1)*t+ch(2)*t^2+ch(3)*t^3+ch(4)*t^4+ch(5)*t^5
```

D.5.2.48 toddPoly

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `toddPoly(td, t)`; td list of polynomials, t polynomial

Return: polynomial

Purpose: computes the polynomial in t corresponding to the Todd class

Note: does the same as `chernPoly(...)`

Example:

```
LIB "chern.lib";
ring r=0, (td(1..5), c(1..5), t), ds;
list l=td(1..5);
// get the polynomial 1 + td(1)*t + td(2)*t^2 + ... + td(5)*t^5
print( toddPoly(l, t) );
↪ 1+td(1)*t+td(2)*t^2+td(3)*t^3+td(4)*t^4+td(5)*t^5
```

D.5.2.49 rHRR

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `rHRR(N, ch, td);` N integer, ch, td lists of polynomials

Return: polynomial

Purpose: computes the the main ingredient of the right-hand side of the Hirzebruch-Riemann-Roch formula

Note: in order to get the right-hand side of the HRR formula
one needs to be able to compute the degree of the output of this procedure

Example:

```
LIB "chern.lib";
ring r=0, (td(0..3), ch(0..3)), dp;
// Let ch(0), ch(1), ch(2), ch(3) be the terms of the Chern character
// of a vector bundle E on a 3-fold X.
list c = ch(0..3);
// Let td(0), td(1), td(2), td(3) be the terms of the Todd class of X.
list t = td(0..3);
// Then the highest term of the product ch(E).td(X) is:
print( rHRR(3, c, t) );
↪ td(3)*ch(0)+td(2)*ch(1)+td(1)*ch(2)+td(0)*ch(3)
```

D.5.2.50 SchurS

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `SchurS(I, S);` I list of integers representing a partition, S list of polynomials

Return: poly

Purpose: computes the Schur polynomial in the Segre classes S (of the dual vector bundle), i.e., in the complete homogeneous symmetric polynomials, with respect to the partition I

Note: if S are the Segre classes of the tautological bundle on a grassmanian, this gives the cohomology class of a Schubert cycle

Example:

```
LIB "chern.lib";
// The Schur polynomial corresponding to the partition 1,2,4
// and the Segre classes 1, s(1), s(2),..., s(6)
ring r=0,(s(1..6)), dp;
list I=1,2,4;
list S=s(1..6);
print( SchurS(I, S) );
↪ s(1)*s(2)*s(4)-s(1)^2*s(5)-s(3)*s(4)+s(1)*s(6)
// compare this with the Schur polynomial computed using Chern classes
list C=chDual(chern(S));
print( SchurCh(I, C) );
↪ s(1)*s(2)*s(4)-s(1)^2*s(5)-s(3)*s(4)+s(1)*s(6)
```

D.5.2.51 SchurCh

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `SchurCh(I, C)`; I list of integers representing a partition, C list of polynomials

Return: `poly`

Purpose: computes the Schur polynomial in the Chern classes C, i.e., in the elementary symmetric polynomials, with respect to the partition I

Note: if C are the Chern classes of the tautological bundle on a grassmanian, this gives the cohomology class of a Schubert cycle

Example:

```
LIB "chern.lib";
// The Schur polynomial corresponding to the partition 1,2,4
// and the Chern classes c(1), c(2), c(3)
ring r=0,(c(1..3)), dp;
list I=1,2,4;
list C=c(1..3);
print( SchurCh(I, C) );
⇒ c(1)^2*c(2)*c(3)-c(2)^2*c(3)-c(1)*c(3)^2
// Compare this with the Schur polynomial computed using Segre classes
list S=segre( chDual( list(c(1..3)) ), 6 );
print(SchurS(I,S));
⇒ c(1)^2*c(2)*c(3)-c(2)^2*c(3)-c(1)*c(3)^2
```

D.5.2.52 part

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `part(m, n)`; m positive integer, n non-negative integer

Return: list of lists

Purpose: computes all partitions of integers not exceeding n into m non-negative summands

Note: if n is negative or m is non-positive, the list with one empty entry is returned

Example:

```
LIB "chern.lib";
// partitions into 3 summands of numbers not exceeding 1
print( part(3, 1) );
⇒ [1]:
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 0
⇒ [3]:
⇒ 0
⇒ [2]:
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 0
⇒ [3]:
⇒ 1
```

```

⇒ [3]:
⇒   [1]:
⇒     0
⇒   [2]:
⇒     1
⇒   [3]:
⇒     1
⇒ [4]:
⇒   [1]:
⇒     1
⇒   [2]:
⇒     1
⇒   [3]:
⇒     1

```

D.5.2.53 dualPart

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `dualPart(I [,N]);` I list of integers, N integer

Return: list of integers

Purpose: computes the partition dual (conjugate) to I

Note: the result is extended by zeroes to length N if an optional integer parameter N is given and the length of the computed dual partition is smaller than N

Example:

```

LIB "chern.lib";
// dual partition to (1, 3, 4):
list I = 1, 3, 4;
print( dualPart(I) );
⇒ [1]:
⇒   1
⇒ [2]:
⇒   2
⇒ [3]:
⇒   2
⇒ [4]:
⇒   3

```

D.5.2.54 PartC

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `PartC(I, m);` I list of integers, m integer

Return: list of integers

Purpose: computes the complement of a partition with respect to m

Note: returns the zero partition if the maximal element of the partition is smaller than m

Example:

```

LIB "chern.lib";
// Complement of the partition (1, 3, 4) with respect to 5

```

```

list I = 1, 3, 4;
print( PartC(I, 5) );
↳ [1]:
↳ 1
↳ [2]:
↳ 2
↳ [3]:
↳ 4

```

D.5.2.55 partOver

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `partOver(n, J);` `n` integer, `J` list of integers (partition)

Return: list of lists

Purpose: computes the partitions over a given one with summands not exceeding `n`

Note:

Example:

```

LIB "chern.lib";
// Partitions over the partition (3, 3, 4) with summands not exceeding 4
list I = 3, 3, 4;
print( partOver(4, I) );
↳ [1]:
↳ [1]:
↳ 3
↳ [2]:
↳ 3
↳ [3]:
↳ 4
↳ [2]:
↳ [1]:
↳ 3
↳ [2]:
↳ 4
↳ [3]:
↳ 4
↳ [3]:
↳ [1]:
↳ 4
↳ [2]:
↳ 4
↳ [3]:
↳ 4

```

D.5.2.56 partUnder

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: `partUnder(J);` `J` list of integers (partition)

Return: list of lists

Purpose: computes the partitions under a given one

Note:

Example:

```
LIB "chern.lib";
// Partitions under the partition (0, 1, 1)
list I = 0, 1, 1;
print( partUnder(I) );
⇒ [1]:
⇒   [1]:
⇒     0
⇒   [2]:
⇒     0
⇒   [3]:
⇒     0
⇒ [2]:
⇒   [1]:
⇒     0
⇒   [2]:
⇒     0
⇒   [3]:
⇒     1
⇒ [3]:
⇒   [1]:
⇒     0
⇒   [2]:
⇒     1
⇒   [3]:
⇒     1
```

D.5.2.57 SegreA

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\]](#), page 1395).

Usage: SegreA(I); I an ideal

Return: list of integers

Purpose: computes the Segre classes of the subscheme defined by I

Note:

Example:

```
LIB "chern.lib";
// Consider a 3-dimensional projective space
ring r = 0, (x, y, z, w), dp;
// Consider 3 non-coplanar lines through one point and compute the Segre class
ideal I=xy, xz, yz;
I;
⇒ I[1]=xy
⇒ I[2]=xz
⇒ I[3]=yz
SegreA(I);
⇒ [1]:
⇒   0
⇒ [2]:
⇒   0
```

```

⇒ [3]:
⇒ 3
⇒ [4]:
⇒ -10
// Now consider 3 coplanar lines trough one point and its Segre class
ideal J=w, x*y*(x+y);
J;
⇒ J[1]=w
⇒ J[2]=x2y+xy2
SegreA(J);
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 0
⇒ [3]:
⇒ 3
⇒ [4]:
⇒ -12

```

D.5.2.58 FultonA

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: FultonA(I); I an ideal

Return: list of integers

Purpose: computes the Fulton classes of the subscheme defined by I

Note:

Example:

```

LIB "chern.lib";
// Consider a 3-dimensional projective space
ring r = 0, (x, y, z, w), dp;
// Consider 3 non-coplanar lines trough one point and compute the Fulton class
ideal I=xy, xz, yz;
I;
⇒ I[1]=xy
⇒ I[2]=xz
⇒ I[3]=yz
FultonA(I);
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 0
⇒ [3]:
⇒ 3
⇒ [4]:
⇒ 2
// Now consider 3 coplanar lines trough one point and its Fulton class
ideal J=w, x*y*(x+y);
J;
⇒ J[1]=w
⇒ J[2]=x2y+xy2

```

```

FultonA(J);
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 0
⇒ [3]:
⇒ 3
⇒ [4]:
⇒ 0

```

D.5.2.59 CSMA

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\]](#), page 1395).

Usage: CSMA(I); I an ideal

Return: list of integers

Purpose: computes the Chern-Schwartz-MacPherson classes of the variety defined by I

Note:

Example:

```

LIB "chern.lib";
// consider the projective plane with homogeneous coordinates x, y, z
ring r = 0, (x, y, z), dp;
// the Chern-Schwartz-MacPherson class of a smooth cubic:
ideal I=x3+y3+z3;
I;
⇒ I[1]=x3+y3+z3
CSMA(I);
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 3
⇒ [3]:
⇒ 0
// the Chern-Schwartz-MacPherson class of singular cubic
// that is a union of 3 non-collinear lines:
ideal J=x*y*z;
J;
⇒ J[1]=xyz
CSMA(J);
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 3
⇒ [3]:
⇒ 3
// the Chern-Schwartz-MacPherson class of singular cubic
// that is a union of 3 lines passing through one point
ideal K=x*y*(x+y);
K;
⇒ K[1]=x2y+xy2
CSMA(K);

```

```

⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 3
⇒ [3]:
⇒ 4

```

D.5.2.60 EulerAff

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: EulerAff(I); I an ideal

Return: integer

Purpose: computes the Euler characteristic of the affine variety defined by I

Note:

Example:

```

LIB "chern.lib";
ring r = 0, (x, y), dp;
// compute the Euler characteristic of the affine elliptic curve y^2=x^3+x+1;
ideal I=y2-x3-x-1;
EulerAff(I);
⇒ -1

```

D.5.2.61 EulerProj

Procedure from library `chern.lib` (see [Section D.5.2 \[chern.lib\], page 1395](#)).

Usage: EulerProj(I); I an ideal

Return: integer

Purpose: computes the highest degree term of the Chern-Schwartz-MacPherson class of the variety defined by I, which equals the Euler characteristic

Note: uses CSMA(...)

Example:

```

LIB "chern.lib";
// consider the projective plane with homogeneous coordinates x, y, z
ring r = 0, (x, y, z), dp;
// Euler characteristic of a smooth cubic:
ideal I=x3+y3+z3;
I;
⇒ I[1]=x3+y3+z3
EulerProj(I);
⇒ 0
// Euler characteristic of 3 non-collinear lines:
ideal J=x*y*z;
J;
⇒ J[1]=xyz
EulerProj(J);
⇒ 3
// Euler characteristic of 3 lines passing through one point

```

```

ideal K=x*y*(x+y);
K;
↪ K[1]=x2y+xy2
EulerProj(K);
↪ 4

```

D.5.3 deRham_lib

Library: deRham.lib

Purpose: Computation of deRham cohomology

Authors: Cornelia Rottner, rottner@mathematik.uni-kl.de

Overview: A library for computing the de Rham cohomology of complements of complex affine varieties.

References:

- [OT] Oaku, T.; Takayama, N.: Algorithms of D-modules - restriction, tensor product, localization, and local cohomology groups}, J. Pure Appl. Algebra 156, 267-308 (2001)

- [W3] Walther, U.: Computing the cup product structure for complements of complex affine varieties, J. Pure Appl. Algebra 164, 247-273 (2001)

Procedures:

D.5.3.1 deRhamCohomology

Procedure from library `deRham.lib` (see [Section D.5.3 \[deRham_lib\]](#), [page 1431](#)).

Usage: `deRhamCohomology(L[,choices]);` L a list consisting of polynomials, choices optional list consisting of one up to three strings
 The optional strings may be one of the strings
 -'noCE': compute quasi-isomorphic complexes without using Cartan-Eilenberg resolutions
 -'Vdres': compute quasi-isomorphic complexes using Cartan-Eilenberg resolutions; the CE resolutions are computed via V_d-homogenization and without using Schreyer's method
 -'Sres': compute quasi-isomorphic complexes using Cartan-Eilenberg resolutions in the homogenized Weyl algebra via Schreyer's method
 one of the strings
 -'iterativeloc': compute localizations by factorizing the polynomials and successive localization of the factors
 -'no iterativeloc': compute localizations by directly localizing the product and one of the strings
 -'onlybounds': computes bounds for the minimal and maximal integer roots of the global b-function
 -'exactroots' computes the minimal and maximal integer root of the global b-function
 The default is 'noCE', 'iterativeloc' and 'onlybounds'.

Assume: -The basering must be a polynomial ring over the field of rational numbers

Return: list, where the i th entry is the $(i-1)$ st de Rham cohomology group of the complement of the complex affine variety given by the polynomials in L

Example:

```
LIB "deRham.lib";
ring r = 0,(x,y,z),dp;
list L=(xy,xz);
deRhamCohomology(L);
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 1
⇒ [3]:
⇒ 0
⇒ [4]:
⇒ 1
⇒ [5]:
⇒ 1
```

D.5.3.2 MVComplex

Procedure from library `deRham.lib` (see [Section D.5.3 \[deRham.lib\]](#), page 1431).

Usage: MVComplex(L); L a list of polynomials

Assume: -Basing is a polynomial ring with n variables and rational coefficients - L is a list of non-constant polynomials

Return: ring W : the n th Weyl algebra
 W contains a list MV , which represents the Mayer-Vietoris complex (C^i, d^i) of the polynomials contained in L as follows:
the C^i are given by $D_n \cdot \text{ncols}(C[2*i-1]) / \text{im}(C[2*i-1])$ and the differentials d^i are given by $C[2*i]$

Example:

```
LIB "deRham.lib";
ring r = 0,(x,y,z),dp;
list L=xy,xz;
def C=MVComplex(L);
setring C;
MV;
⇒ [1]:
⇒ _[1,1]=D(3)
⇒ _[1,2]=0
⇒ _[2,1]=x(1)*D(1)+1
⇒ _[2,2]=0
⇒ _[3,1]=-x(2)*D(2)-1
⇒ _[3,2]=0
⇒ _[4,1]=0
⇒ _[4,2]=D(2)
⇒ _[5,1]=0
⇒ _[5,2]=x(1)*D(1)+1
```

```

⇒      _[6,1]=0
⇒      _[6,2]=-x(3)*D(3)-1
⇒      [2]:
⇒      _[1,1]=-x(1)*x(3)
⇒      _[2,1]=x(1)*x(2)
⇒      [3]:
⇒      _[1,1]=x(2)*D(2)+1
⇒      _[2,1]=x(1)*D(1)+2
⇒      _[3,1]=-x(3)*D(3)-1
⇒      [4]:
⇒      _[1,1]=0

```

D.5.4 divisors_lib

Library: divisors.lib

Purpose: Divisors and P-Divisors

Authors: Janko Boehm boehm@mathematik.uni-kl.de
 Lars Kastner kastner@math.fu-berlin.de
 Benjamin Lorenz blorenz@math.uni-frankfurt.de
 Hans Schoenemann hannes@mathematik.uni-kl.de
 Yue Ren ren@mathematik.uni-kl.de

Overview: We implement a class divisor on an algebraic variety and methods for computing with them. Divisors are represented by tuples of ideals defining the positive and the negative part. In particular, we implement the group structure on divisors, computing global sections and testing linear equivalence.

In addition to this we provide a class formaldivisor which implements integer formal sums of divisors (not necessarily prime). A formal divisor can be evaluated to a divisor, and a divisor can be decomposed into a formal sum.

Finally we provide a class pdivisor which implements polyhedral formal sums of divisors (P-divisors) where the coefficients are assumed to be polyhedra with fixed tail cone. There is a function to evaluate a P-divisor on a vector in the dual of the tail cone. The result will be a formal divisor.

References:

For the class divisor we closely follow Macaulay2's tutorial on divisors.

Procedures:

D.5.4.1 makeDivisor

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors_lib\]](#), page 1433).

Usage: `makeDivisor(I ,J);` I = ideal, J = ideal.

Assume: I and J are ideals in a qring Q of a smooth irreducible variety X such that any ideal in Q satisfies the S2 condition.

Return: a divisor on X

Theory: The procedure will eliminate all components which are not of codimension 1. The S2 condition requires that every proper nonzero principal ideal has pure codimension 1.

Example:

```
LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor P = makeDivisor(ideal(x,z),ideal(1));
```

D.5.4.2 divisorplus

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\]](#), page 1433).

Usage: `divisorplus(A ,B);` $A + B$; $A = \text{divisor}$, $B = \text{divisor}$.

Assume: A and B are divisors on X .

Return: a divisor on X

Theory: The procedure will compute the product of the numerator and denominator ideals, respectively.

Example:

```
LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor A = makeDivisor(ideal(x,z),ideal(1));
divisor B = makeDivisor(ideal(x,y),ideal(1));
A+B;
 $\mapsto (x,yz) - (1)$ 
 $\mapsto$ 
```

D.5.4.3 multdivisor

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\]](#), page 1433).

Usage: `multdivisor(n ,A);` A^n ; $n = \text{integer}$, $A = \text{divisor}$.

Assume: n is an integer and A is a divisor on X .

Return: a divisor on X

Theory: The procedure will compute the n -th power of the numerator and denominator ideals, respectively.

Example:

```
LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor A = makeDivisor(ideal(x,z),ideal(1));
A;
 $\mapsto (z,x) - (1)$ 
 $\mapsto$ 
divisor D = multdivisor(4,A);
D;
```

```

 $\mapsto (z^2, xz) - (1)$ 
 $\mapsto$ 
A*4;
 $\mapsto (z^2, xz) - (1)$ 
 $\mapsto$ 

```

D.5.4.4 negativedivisor

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\]](#), page 1433).

Usage: `negativedivisor(A); A*(-1); A = divisor.`

Assume: A is a divisor on X.

Return: a divisor on X

Theory: The procedure will interchange the numerator and denominator ideals.

Example:

```

LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor A = makeDivisor(ideal(x,z),ideal(1));
A;
 $\mapsto (z, x) - (1)$ 
 $\mapsto$ 
divisor D = negativedivisor(A);
D;
 $\mapsto (1) - (z, x)$ 
 $\mapsto$ 

```

D.5.4.5 normalForm

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\]](#), page 1433).

Usage: `normalForm(A); A = divisor.`

Assume: A is a divisor on X.

Return: different representative of the same divisor on X

Theory: The procedure will cancel common components of numerator and denominator.

Example:

```

LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor A = makeDivisor(ideal(x,z),ideal(1));
divisor B = makeDivisor(ideal(x,y),ideal(1));
divisor D = (A+B)+multdivisor(-1,B);
D;
 $\mapsto (x, yz) - (y, x)$ 
 $\mapsto$ 

```

```
normalForm(D);
 $\mapsto (z,x) - (1)$ 
 $\mapsto$ 
```

D.5.4.6 isEqualDivisor

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\]](#), page 1433).

Usage: `isEqualDivisor(A,B);` A = divisor, B = divisor.

Assume: A and B are divisors on X.

Return: int 0 or 1, checks equality of A and B.

Theory: The procedure will compute the normal forms of A and B and compare.

Example:

```
LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor A = makeDivisor(ideal(x,z),ideal(1));
divisor B = makeDivisor(ideal(x,y),ideal(1));
divisor D = (A+B)+multdivisor(-1,B);
isEqualDivisor(A,D);
 $\mapsto 1$ 
```

D.5.4.7 globalSections

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\]](#), page 1433).

Usage: `globalSections(A);` A = divisor.

Assume: A is a divisor on X.

Return: a list with a basis of the space of global sections of D.

Theory: We assume that the qring of X satisfies the S2-condition and that X is smooth. We compute $\text{sat}((f^*J) : I) / f$ where $D = (I) - (J)$.

Example:

```
LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor P = makeDivisor(ideal(x,z),ideal(1));
divisor D = multdivisor(4,P);
globalSections(D);
 $\mapsto [1]:$ 
 $\mapsto \_ [1]=x^2$ 
 $\mapsto \_ [2]=z^2$ 
 $\mapsto \_ [3]=yz$ 
 $\mapsto \_ [4]=xz$ 
 $\mapsto [2]:$ 
 $\mapsto z^2$ 
```

D.5.4.8 degreeDivisor

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\], page 1433](#)).

Usage: `degreeDivisor(A)`; $A = \text{divisor}$.

Assume: A is a divisor on X .

Return: The degree of A .

Theory: We compute difference of the degrees of the numerator and denominator ideals.

Example:

```
LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor P = makeDivisor(ideal(x,z),ideal(1));
degreeDivisor(P);
↪ 1
```

D.5.4.9 linearlyEquivalent

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\], page 1433](#)).

Usage: `linearlyEquivalent(A,B)`; $A = \text{divisor}$, $B = \text{divisor}$.

Assume: A and B are divisors on X .

Return: list if A and B are linearly equivalent and int 0 otherwise.

Theory: Checks whether $A-B$ is principle. If yes, returns a list $L=(f,g)$ where $A - B = (f/g)$.

Example:

```
LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor A = makeDivisor(ideal(x,z),ideal(1));
divisor B = makeDivisor(ideal(x,y),ideal(1));
linearlyEquivalent(A,B);
↪ 0
linearlyEquivalent(multdivisor(2,A),multdivisor(2,B));
↪ [1]:
↪ x
↪ [2]:
↪ z
```

D.5.4.10 effective

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\], page 1433](#)).

Usage: `effective(A)`; $A = \text{divisor}$.

Assume: A is a divisor on X which is linearly equivalent to an effective divisor.

Return: divisor on X.

Theory: We compute an effective divisor linearly equivalent to A.

Example:

```
LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor A = makeDivisor(ideal(x,z),ideal(1));
divisor B = makeDivisor(ideal(x,y),ideal(1));
divisor D = divisorplus(multdivisor(2,B),negativedivisor(A));
effective(D);
 $\mapsto (z,x) - (1)$ 
 $\mapsto$ 
```

D.5.4.11 makeFormalDivisor

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\]](#), page 1433).

Usage: `makeFormalDivisor(L)`; L = list.

Assume: L is a list of tuples of an integer and a divisor.

Return: a formal divisor on X

Theory: Represents an integer formal sum of divisors.

Example:

```
LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor A = makeDivisor(ideal(x,z),ideal(1));
divisor B = makeDivisor(ideal(x,y),ideal(1));
makeFormalDivisor(list(list(-5,A),list(2,B)));
 $\mapsto -5*((z,x) - (1))$ 
 $\mapsto +2*((y,x) - (1))$ 
 $\mapsto$ 
```

D.5.4.12 evaluateFormalDivisor

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\]](#), page 1433).

Usage: `evaluateFormalDivisor(D)`; D = formal divisor.

Assume: D is a formal divisor on X.

Return: a divisor on X

Theory: Will evaluate the formal sum.

Example:

```
LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
```

```

qring Q = std(I);
divisor A = makeDivisor(ideal(x,z),ideal(1));
divisor B = makeDivisor(ideal(x,y),ideal(1));
formaldivisor fE= makeFormalDivisor(list(list(-5,A),list(2,B)));
evaluateFormalDivisor(fE);
 $\mapsto (x,y^2) - (z^2,x^2z)$ 
 $\mapsto$ 

```

D.5.4.13 formaldivisorplus

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\]](#), page 1433).

Usage: `formaldivisorplus(A ,B);` $A + B$; $A =$ formaldivisor, $B =$ formaldivisor.

Assume: A and B are formal divisors on X .

Return: a formal divisor on X

Theory: The procedure will add the formal sums.

Example:

```

LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor A = makeDivisor(ideal(x,z),ideal(1));
divisor B = makeDivisor(ideal(x,y),ideal(1));
divisor C = makeDivisor(ideal(x-z,y),ideal(1));
formaldivisor fE= makeFormalDivisor(list(list(-5,A),list(2,B)));
formaldivisor fE2= makeFormalDivisor(list(list(-5,A),list(2,C)));
formaldivisorplus(fE,fE2);
 $\mapsto$  [1]:
 $\mapsto$  [1]:
 $\mapsto$  -10
 $\mapsto$  [2]:
 $\mapsto (z,x) - (1)$ 
 $\mapsto$ 
 $\mapsto$  [2]:
 $\mapsto$  [1]:
 $\mapsto$  2
 $\mapsto$  [2]:
 $\mapsto (y,x) - (1)$ 
 $\mapsto$ 
 $\mapsto$  [3]:
 $\mapsto$  [1]:
 $\mapsto$  2
 $\mapsto$  [2]:
 $\mapsto (y,x-z) - (1)$ 
 $\mapsto$ 

```

D.5.4.14 negativeformaldivisor

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\]](#), page 1433).

Usage: `negativeformaldivisor(A)`; A = formaldivisor.

Assume: A is a formaldivisor on X .

Return: a formal divisor on X

Theory: The procedure will change the signs of the coefficients.

Example:

```
LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor A = makeDivisor(ideal(x,z),ideal(1));
divisor B = makeDivisor(ideal(x,y),ideal(1));
formaldivisor fE= makeFormalDivisor(list(list(-5,A),list(2,B)));
negativeformaldivisor(fE);
 $\mapsto 5*( (z,x) - (1) )$ 
 $\mapsto -2*( (y,x) - (1) )$ 
 $\mapsto$ 
```

D.5.4.15 multformaldivisor

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\]](#), page 1433).

Usage: `multformaldivisor(n ,A)`; A^n ; n = integer, A = formaldivisor.

Assume: n is an integer and A is a formal divisor on X .

Return: a formal divisor on X

Theory: The procedure will multiply the formal sum with n .

Example:

```
LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor A = makeDivisor(ideal(x,z),ideal(1));
divisor B = makeDivisor(ideal(x,y),ideal(1));
formaldivisor fE= makeFormalDivisor(list(list(-5,A),list(2,B)));
fE*2;
 $\mapsto -10*( (z,x) - (1) )$ 
 $\mapsto +4*( (y,x) - (1) )$ 
 $\mapsto$ 
```

D.5.4.16 degreeFormalDivisor

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\]](#), page 1433).

Usage: `degreeFormalDivisor(A)`; A = formaldivisor.

Assume: A is a formaldivisor on X .

Return: The degree of A .

Theory: We compute degrees of the summands and return the weighted sum.

Example:

```
LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor A = makeDivisor(ideal(x,z),ideal(1));
divisor B = makeDivisor(ideal(x,y),ideal(1));
formaldivisor fE= makeFormalDivisor(list(list(-5,A),list(2,B)));
degreeFormalDivisor(fE);
↦ -3
```

D.5.4.17 makePDivisor

Procedure from library `divisors.lib` (see [Section D.5.4 \[divisors.lib\]](#), page 1433).

Usage: `makePDivisor(L); L = list.`

Assume: `L` is a list of tuples of a integral polyhedron and a divisor such that all polyhedra have the same tail cone.

Return: a pdivisor on `X`

Theory: Represents an polyhedral formal sum of divisors.

Example:

```
LIB "divisors.lib";
ring r=31991,(x,y,z),dp;
ideal I = y^2*z - x*(x-z)*(x+3*z);
qring Q = std(I);
divisor A = makeDivisor(ideal(x,z),ideal(1));
divisor B = makeDivisor(ideal(x,y),ideal(1));
intmat M[4][4]= 1,4,0,0,
1,0,3,0,
0,0,0,2,
1,1,1,1;
polytope PP = polytopeViaPoints(M);
makePDivisor(list(list(PP,A),list(PP,B)));
↦ tail=<cone>
↦ summands=<list>
```

D.5.5 goettsche_lib

Library: `goettsche.lib`

Purpose: Drezet's formula for the Betti numbers of the moduli space of Kronecker modules; Goettsche's formula for the Betti numbers of the Hilbert scheme of points on a surface; Nakajima's and Yoshioka's formula for the Betti numbers of the punctual Quot-schemes on a plane or, equivalently, of the moduli spaces of the framed torsion-free planar sheaves; Macdonald's formula for the symmetric product

Author: Oleksandr Iena, o.g.yena@gmail.com

Procedures:**D.5.5.1 GoettscheF**

Procedure from library `goettsche.lib` (see [Section D.5.5 \[goettsche.lib\]](#), page 1441).

Usage: `GoettscheF(z, t, n, b)`; `z, t` polynomials, `n` integer, `b` list of non-negative integers

Return: polynomial in `z` and `t`

Purpose: computes the Goettsche's formula up to degree `n` in `t`

Note: zero is returned if `n < 0` or `b` is not a list of non-negative integers or if there are not enough Betti numbers

Example:

```
LIB "goettsche.lib";
ring r=0, (t, z), ls;
// consider the projective plane with Betti numbers 1,0,1,0,1
list b=1,0,1,0,1;
// get the Goettsche's formula up to degree 3
print( GoettscheF(z, t, 3, b) );
↪ 1+t+tz2+tz4+t2+2t2z2+3t2z4+2t2z6+t2z8+t3+2t3z2+5t3z4+6t3z6+5t3z8+2t3z10+t\
3z12
```

D.5.5.2 PPolyH

Procedure from library `goettsche.lib` (see [Section D.5.5 \[goettsche.lib\]](#), page 1441).

Usage: `PPolyH(z, n, b)`; `z` polynomial, `n` integer, `b` list of non-negative integers

Return: polynomial in `z`

Purpose: computes the Poincare polynomial of the Hilbert scheme of `n` points on a surface with Betti numbers `b`

Note: zero is returned if `n < 0` or `b` is not a list of non-negative integers or if there are not enough Betti numbers

Example:

```
LIB "goettsche.lib";
ring r=0, (z), ls;
// consider the projective plane P_2 with Betti numbers 1,0,1,0,1
list b=1,0,1,0,1;
// get the Poincare polynomial of the Hilbert scheme of 3 points on P_2
print( PPolyH(z, 3, b) );
↪ 1+2z2+5z4+6z6+5z8+2z10+z12
```

D.5.5.3 BettiNumsH

Procedure from library `goettsche.lib` (see [Section D.5.5 \[goettsche.lib\], page 1441](#)).

Usage: `BettiNumsH(n, b)`; `n` integer, `b` list of non-negative integers

Return: list of non-negative integers

Purpose: computes the Betti numbers of the Hilbert scheme of `n` points on a surface with Betti numbers `b`

Note: an empty list is returned if `n < 0` or `b` is not a list of non-negative integers or if there are not enough Betti numbers

Example:

```
LIB "goettsche.lib";
ring r=0, (z), ls;
// consider the projective plane P_2 with Betti numbers 1,0,1,0,1
list b=1,0,1,0,1;
// get the Betti numbers of the Hilbert scheme of 3 points on P_2
print( BettiNumsH(3, b) );

```

D.5.5.4 NakYoshF

Procedure from library `goettsche.lib` (see [Section D.5.5 \[goettsche.lib\], page 1441](#)).

Usage: `NakYoshF(z, t, r, n)`; `z, t` polynomials, `r, n` integers

Return: polynomial in `z` and `t`

Purpose: computes the formula of Nakajima and Yoshioka
up to degree n in t

Note: zero is returned if $n < 0$ or $r \leq 0$

Example:

```
LIB "goettsche.lib";
ring r=0, (t, z), ls;
// get the Nakajima-Yoshioka formula for r=1 up to degree 3, i.e.,
// the generating function for the Poincare polynomials of the
// punctual Hilbert schemes of n planar points
print( NakYoshF(z, t, 1, 3) );
↪ 1+t+t2+t2z2+t3+t3z2+t3z4
```

D.5.5.5 PPolyQp

Procedure from library `goettsche.lib` (see [Section D.5.5 \[goettsche.lib\], page 1441](#)).

Usage: PPolyQp(z, r, n); z polynomial, r, n integers

Return: polynomial in z

Purpose: computes the Poincare polynomial of the punctual Quot-scheme of rank r on n planar points

Note: zero is returned if $n < 0$ or $r \leq 0$

Example:

```
LIB "goettsche.lib";
ring r=0, (z), ls;
// get the Poincare polynomial of the punctual Hilbert scheme (r=1)
// of 3 planar points
print( PPolyQp(z, 1, 3) );
↪ 1+z2+z4
```

D.5.5.6 BettiNumsQp

Procedure from library `goettsche.lib` (see [Section D.5.5 \[goettsche.lib\], page 1441](#)).

Usage: BettiNumsQp(r, n); n, r integers

Return: list of non-negative integers

Purpose: computes the Betti numbers of the punctual Quot-scheme of rank r on n points on a plane

Note: an empty list is returned if $n < 0$ or $r \leq 0$

Example:

```
LIB "goettsche.lib";
ring r=0, (z), ls;
// get the Betti numbers of the punctual Hilbert scheme (r=1)
// of 3 points on a plane
print( BettiNumsQp(1, 3) );
↪ [1]:
↪ 1
↪ [2]:
↪ 0
```

```

↦ [3] :
↦      1
↦ [4] :
↦      0

↦      1

```

D.5.5.7 MacdonaldF

Procedure from library `goettsche.lib` (see [Section D.5.5 \[goettsche.lib\]](#), page 1441).

Usage: `MacdonaldF(z, t, n, b)`; `z, t` polynomials, `n` integer, `b` list of non-negative integers

Return: polynomial in `z` and `t` with integer coefficients

Purpose: computes the Macdonalds's formula up to degree `n` in `t`

Note: zero is returned if `n < 0` or `b` is not a list of non-negative integers

Example:

```

LIB "goettsche.lib";
ring r=0, (t, z), ls;
// consider the projective plane with Betti numbers 1,0,1,0,1
list b=1,0,1,0,1;
// get the Macdonald's formula up to degree 3
print( MacdonaldF(z, t, 3, b) );
↦ 1+t+tz2+tz4+t2+t2z2+2t2z4+t2z6+t2z8+t3+t3z2+2t3z4+2t3z6+2t3z8+t3z10+t3z12

```

D.5.5.8 PPolyS

Procedure from library `goettsche.lib` (see [Section D.5.5 \[goettsche.lib\]](#), page 1441).

Usage: `PPolyS(z, n, b)`; `z` polynomial, `n` integer, `b` list of non-negative integers

Return: polynomial in `z` with integer coefficients

Purpose: computes the Poincare polynomial of the `n`-th symmetric power of a variety with Betti numbers `b`

Note: zero is returned if `n < 0` or `b` is not a list of non-negative integers

Example:

```

LIB "goettsche.lib";
ring r=0, (z), ls;
// consider the projective plane P_2 with Betti numbers 1,0,1,0,1
list b=1,0,1,0,1;
// get the Poincare polynomial of the third symmetric power of P_2
print( PPolyS(z, 3, b) );
↦ 1+z2+2z4+2z6+2z8+z10+z12

```

D.5.5.9 BettiNumsS

Procedure from library `goettsche.lib` (see [Section D.5.5 \[goettsche.lib\]](#), page 1441).

Usage: `BettiNumsS(n, b)`; `n` integer, `b` list of non-negative integers

Return: list of non-negative integers

Purpose: computes the Betti numbers of the n -th symmetric power of a variety with Betti numbers b

Note: an empty list is returned if $n < 0$ or b is not a list of non-negative integers

Example:

```
LIB "goettsche.lib";
ring r=0, (z), ls;
// consider a complex torus T (elliptic curve) with Betti numbers 1,2,1
list b=1,2,1;
// get the Betti numbers of the second symmetric power of T

```

D.5.5.10 PPolyN

Procedure from library `goettsche.lib` (see [Section D.5.5 \[goettsche.lib\], page 1441](#)).

Usage: `PPolyN(t, q, m, n)`; t polynomial, q, m, n integers

Return: polynomial in t

Purpose: computes the Poincare polynomial of the moduli space of Kronecker modules $N(q; m, n)$

Note: if m and n are not coprime, the result does not necessary make sense

Example:

```
LIB "goettsche.lib";
ring r=0, (t), ls;
// get the Poincare polynomial of N(3; 2, 3)
print( PPolyN(t, 3, 2, 3) );
↪ 1+t2+3t4+3t6+3t8+t10+t12
```

D.5.5.11 BettiNumsN

Procedure from library `goettsche.lib` (see [Section D.5.5 \[goettsche.lib\], page 1441](#)).

Usage: `BettiNumsN(q, m, n)`; q, m, n integers

Return: list of integers

Purpose: computes the Betti numbers of the moduli space of Kronecker modules $N(q; m, n)$

Note: if m and n are not coprime, the result does not necessary make sense

Example:

```
LIB "goettsche.lib";
ring r=0, (t), dp;
// get the Betti numbers of N(3; 2, 3)
print( BettiNumsN(3, 2, 3) );

D.5.6 graal_lib

Library: graal.lib

Purpose: localization at prime ideals and their associated graded rings

Author: Magdaleen Marais, magdaleen@aims.ac.za
 Yue Ren, ren@mathematik.uni-kl.de

Overview: This library is on a computational treatment of localizations at prime ideals and their associated graded rings based on a work of Mora. Not only does it construct a ring isomorphic to the localization of an affine coordinate ring at a prime ideal, the algorithms in this library aim to exploit the topology in the localization by computing first and foremost in the associated graded ring and lifting the result to the localization afterwards.
 Features include a check for regularity and the resolution of ideals.

References:

Mora, Teo: La queste del Saint Gr_a(A.L): A computational approach to local algebra
 Marais, Magdaleen and Ren, Yue: Mora's holy graal: Algorithms for computing in localizations at prime ideals

Procedures:

D.5.6.1 graalMixed

Procedure from library `graal.lib` (see [Section D.5.6 \[graal_lib\]](#), page 1448).

Usage: `graalMixed(L,t)`; L ideal, t int (optional)

Return: `graalBearer` with all the necessary structures for our machinery if t specified and t>0, puts an upper time limit on finding a necessary transformation to map an intermediate ideal into general position.

Note: assumes that the current basering is a domain and that L is a prime ideal.

Example:

```

LIB "graal.lib";
// see [Mora] Example 6.5
ring Q = 0,(x,y,z),dp;
ideal H = y2-xz;
qring A = std(H);
ideal L = x3-yz,x2y-z2;
graalBearer Gr = graalMixed(L); Gr;
↦ affine coordinate ring:
↦      (QQ),(x,y,z),(dp(3),C)
↦      mod <y2-xz>
↦

```

```

⇒ ideal defining the subvariety:
⇒   <x3-yz,x2y-z2>
⇒
⇒ A1:
⇒   (0,z),(Y(1),Y(2),x,y),(ds(2),c,dp(2))
⇒   mod <x^3+(-z)*y-Y(1),x^2*y+(-z^2)-Y(2),y^2+(-z)*x,(z)*Y(1)-Y(2)*y>
⇒ graal:
⇒   (0,z),(Y(1),Y(2),y),(c,dp(2),dp(1))
⇒   mod <(z)*Y(1)-Y(2)*y,y^5+(-z^4)>
⇒   where
⇒   Y(1) represents generator x3-yz
⇒   Y(2) represents generator x2y-z2
⇒   and x,y in A1 are mapped to 1/(z)*y^2,y in Graal
⇒

```

D.5.6.2 dimensionOfLocalization

Procedure from library `graal.lib` (see [Section D.5.6 \[graal.lib\], page 1448](#)).

Usage: `dimensionOfLocalization(L)`; L ideal or `graalBearer`

Return: int, the dimension of the localization A_L of A at L.

Example:

```

LIB "graal.lib";
ring Q = 0,(X(1),X(2)),dp;
ideal H = X(2)^2-(X(1)-1)*X(1)*(X(1)+1);
ideal J = std(X(1),X(2));
⇒ // ** _ is no standard basis
qring A = std(H);
ideal L = fetch(Q,J);
graalBearer Gr = graalMixed(L);
// def fA = Gr.fA; setring fA;
dimensionOfLocalization(Gr); // = 1
⇒ // ** redefining scriptIin (   ideal scriptIin = Gr.scriptIin;) graal.li\
   b::dimensionOfLocalization:582
⇒ 1

```

D.5.6.3 systemOfParametersOfLocalization

Procedure from library `graal.lib` (see [Section D.5.6 \[graal.lib\], page 1448](#)).

Usage: `systemOfParametersOfLocalization(def L)`; L ideal or `graalBearer`

Return: ideal, a system of parameter of the localization A_L of A at L.

Example:

```

LIB "graal.lib";
ring Q = 0,(X(1),X(2)),dp;
ideal H = X(2)^2-(X(1)-1)*X(1)*(X(1)+1);
ideal J = X(1),X(2);
qring A = std(H);
ideal L = fetch(Q,J);
graalBearer Gr = graalMixed(L);
systemOfParametersOfLocalization(Gr); // = 1
⇒ // ** redefining J (   ideal J = Gr.J; ideal ret;) graal.lib::systemOfPa\

```

```
rametersOfLocalization:647
↦ _[1]=X(2)
```

D.5.6.4 isLocalizationRegular

Procedure from library `graal.lib` (see [Section D.5.6 \[graal.lib\]](#), page 1448).

Usage: `isLocalizationRegular(def L);` L ideal or `graalBearer`

Return: int, 1 if the localization A_L of A at L is regular,
0 otherwise.

Example:

```
LIB "graal.lib";
ring Q = 0, (X(1), X(2)), dp;
ideal H = X(2)^2 - (X(1)-1)*X(1)*(X(1)+1);
ideal J = X(1), X(2);
qring A = std(H);
ideal L = fetch(Q, J);
graalBearer Gr = graalMixed(L);
isLocalizationRegular(Gr); // = 1
↦ 1
```

D.5.6.5 warkedPreimageStd

Procedure from library `graal.lib` (see [Section D.5.6 \[graal.lib\]](#), page 1448).

Usage: `warkedPreimageStd(wM);` M warkedModule

Return: given wM consisting of:

- wM.Gr a `graalBearer` containing all relevant global structures
- wM.modQ0y generating set G of a module M over Q0y - wM.stdmodQ0y empty
- wM.qQ0y empty
- wM.modKy corresponding generating set H of M_{in} over Ky - wM.stdmodKy empty
- wM.qKy empty
- wM.w weights on M

returns the same warkedModule, except following differences:

- wM.stdmodQ0y contains a subset G such that for any standard basis L of the kernel $G + L$ is a standard basis of $\text{modQ0y} + \text{kernel}$

- wM.qQ0y contains a transformation matrix such that $\text{stdmodAy} = \text{QAy} * \text{modQ0y}$
- wM.stdmodKy contains a standardbasis of modKy
- wM.qKy contains a transformation matrix such that $\text{stdmodKy} = \text{QKy} * \text{modKy}$

Note: the standard basis of modAy is computed by lifting a corresponding Groebner basis of modKy

Example:

```
LIB "graal.lib";
ring Q = 0, (x, y, z), dp;
ideal H = y^2 - xz;
qring A = std(H);
ideal L = x^3 - yz, x^2y - z^2;
graalBearer Gr = graalMixed(L);
def Q0y = Gr.Q0y; setring Q0y;

D.5.6.6 resolutionInLocalization

Procedure from library `graal.lib` (see [Section D.5.6 \[graal.lib\]](#), page 1448).

Usage: `resolutionInLocalization(I,L)`; I ideal, L ideal or `graalBearer`

Return: the resolution of $I \cdot A_L$, where
 A_L is the localization of the current basering (possibly a quotient ring) at a prime ideal L.

Example:

```

LIB "graal.lib";
ring Q = 0,(x,y,z,w),dp;

```

```

ideal circle = (x-1)^2+y^2-3,z;
ideal twistedCubic = xz-y^2,yw-z^2,xw-yz,z;
ideal I = std(intersect(circle,twistedCubic));
// the resolution is more complicated due to the twisted cubic
res(I,0);
⇒ 1      4      5      2
⇒ Q <--  Q <--  Q <--  Q
⇒
⇒ 0      1      2      3
⇒ resolution not minimized yet
⇒
// however if we localize outside of the twisted cubic,
// it should become very easy again.
ideal L = std(I+ideal(x-1));
graalBearer Gr = graalMixed(L); Gr;
⇒ affine coordinate ring:
⇒ (QQ),(x,y,z,w),(dp(4),C)
⇒

D.5.7 hess_lib

Library: hess.lib

Purpose: Riemann-Roch space of divisors on function fields and curves

Authors: I. Stenger: stenger@mathematik.uni-kl.de

Overview: Let f be an absolutely irreducible polynomial in two variables x, y . Assume that f is monic as a polynomial in y . Let $F = \text{Quot}(k[x, y]/f)$ be the function field defined by f . Define $O_F = \text{IntCl}(k[x], F)$ and $O_-(F, \text{inf}) = \text{IntCl}(k[1/x], F)$. We represent a divisor D on F by two fractional ideals I and J of O_F and $O_-(F, \text{inf})$, respectively. The Riemann-Roch space $L(D)$ is then the intersection of $I^{(-1)}$ and $J^{(-1)}$.

Procedures:

D.5.7.1 RiemannRochHess

Procedure from library `hess.lib` (see [Section D.5.7 \[hess_lib\]](#), page 1453).

Note: All fractional ideals must be represented by a list of size two. The first element is an ideal of $k[x, y]$ and the second element the common denominator, i.e., a polynomial of $k[x]$.

Assume: The base ring R must be a ring in two variables, say x, y , or three variables, say x, y, z . If $\text{nvars}(R) = 2$:

- f is an absolutely irreducible polynomial, monic as a polynomial in y .
- List `divisorD` describes a divisor D of $F = \text{Quot}(k[x, y]/f)$. If $(s = \text{"ideals"})$ D is given in ideal representation, i.e., `divisorD` is a list of size 2. `divisorD[1]` is the finite ideal of D , i.e., the fractional ideal of D of $\text{IntCl}(k[x], F)$. `divisorD[2]` is the infinite ideal of D , i.e., the fractional ideal of D of $\text{IntCl}(k[1/x], F)$.

If $(s = \text{"free"})$

D is given in free representation, i.e., `divisorD` is a list of size 2, containing the finite and infinite places of D with exponents.

`divisorD[i]`, $i = 1, 2$, is a list. Each element of the list is again a list. The first entry is a fractional ideal, and the second an integer, the exponent of the place. If $\text{nvars}(R) = 3$:

- f is an absolutely irreducible homogeneous polynomial describing the projective plane curve corresponding to the function field F . We assume that the dehomogenization of f w.r.t. z is monic as a polynomial in y .

List divisorD describes a divisor D of F.

If (s = "ideals")

D is given in ideal representation, i.e., divisorD is a list of size 2. divisorD[1] is an ideal of the base ring representing the positive divisor of D and

divisorD[2] is an ideal of the base ring representing the negative divisor. (i.e. $D = (I) - (J)$).

If (s = "free")

D is given in free representation, i.e., divisorD is a list of places of D. D[i][1] is an prime ideal and D[i][2] an integer, the exponent of the place.

Return: A vector space basis of the Riemann-Roch space of D, stored in a list RRBasis. The list RRBasis contains a list, say rbasis, and a polynomial, say den. The basis of $L(D)$ consists of all rational functions g/den , where g is an element of rbasis.

Example:

```
LIB "hess.lib";
ring R = 0,(x,y),dp;
poly f = y^2*(y-1)^3-x^5;
list A1 = list(ideal(x,y-1),1),2;
list A2 = list(ideal(y^2-y+1,x),1),3;
list A3 = list(ideal(1,y-x),x),-2;
list D = A1,A2;
list E = list(A3);

D.5.8 numerAlg_lib

Todos/Issues:

- does not follow the naming convention
- syntax errors in examples
- no test suite

Library: NumerAlg.lib

Purpose: Numerical Algebraic Algorithm

Overview: The library contains procedures to test the inclusion, the equality of two ideals defined by polynomial systems, compute the degree of a pure i -dimensional component of an algebraic variety defined by a polynomial system, compute the local dimension of an algebraic variety defined by a polynomial system at a point computed as an approximate value. The use of the library requires to install Bertini (<http://www.nd.edu/~sommese/bertini>).

Author: Shawki AlRashed, rashed@mathematik.uni-kl.de; sh.shawki@yahoo.de

Procedures:

D.5.8.1 Incl

Procedure from library `numerAlg.lib` (see [Section D.5.8 \[numerAlg_lib\]](#), page 1455).

Usage: Incl(ideal I, ideal J); I, J ideals

Return: t=1 if the algebraic variety defined by I contains the algebraic variety defined by J,
otherwise t=0

Example:

```
LIB "numerAlg.lib";
ring r=0,(x,y,z),dp;
poly f1=(x2+y2+z2-6)*(x-y)*(x-1);
poly f2=(x2+y2+z2-6)*(x-z)*(y-2);
poly f3=(x2+y2+z2-6)*(x-y)*(x-z)*(z-3);
ideal I=f1,f2,f3;
poly g1=(x2+y2+z2-6)*(x-1);
poly g2=(x2+y2+z2-6)*(y-2);
poly g3=(x2+y2+z2-6)*(z-3);
ideal J=g1,g2,g3;
def W=Incl(I,J);
==>
Inclusion:
0
def W=Incl(J,I);
==>
Inclusion:
1
```

D.5.8.2 Equal

Procedure from library `numerAlg.lib` (see [Section D.5.8 \[numerAlg.lib\]](#), page 1455).

Usage: Equal(ideal I, ideal J); I, J ideals

Return: t=1 if the algebraic variety defined by I equals to the algebraic variety defined by J,
otherwise t=0

Example:

```
LIB "numerAlg.lib";
ring r=0,(x,y,z),dp;
poly f1=(x2+y2+z2-6)*(x-y)*(x-1);
poly f2=(x2+y2+z2-6)*(x-z)*(y-2);
poly f3=(x2+y2+z2-6)*(x-y)*(x-z)*(z-3);
ideal I=f1,f2,f3;
poly g1=(x2+y2+z2-6)*(x-1);
poly g2=(x2+y2+z2-6)*(y-2);
poly g3=(x2+y2+z2-6)*(z-3);
ideal J=g1,g2,g3;
def W=Equal(I,J);
==>
Equality:
0
def W=Equal(J,J);
==>
Equality:
1
```

D.5.8.3 DegreePure

Procedure from library `numerAlg.lib` (see [Section D.5.8 \[numerAlg.lib\], page 1455](#)).

Usage: DegreePure(ideal I,int i); I ideal, i positive integer

Return: the degree of the pure i-dimensional component of the algebraic variety defined by I

Example:

```
LIB "numerAlg.lib";
ring r=0,(x,y,z),dp;
poly f1=(x2+y2+z2-6)*(x-y)*(x-1);
poly f2=(x2+y2+z2-6)*(x-z)*(y-2);
poly f3=(x2+y2+z2-6)*(x-y)*(x-z)*(z-3);
ideal I=f1,f2,f3;
def W=DegreePure(I,1);
==>
The Degree of Component
3
def W=DegreePure(I,2);
==>
The Degree of Component
2
```

D.5.8.4 NumLocalDim

Procedure from library `numerAlg.lib` (see [Section D.5.8 \[numerAlg.lib\], page 1455](#)).

Usage: NumLocalDim(ideal J, list w, int e); J ideal,
w list of an approximate value of a point v in the algebraic variety defined by J, e
integer

Return: the local dimension of the algebraic variety defined by J at v

Example:

```
LIB "numerAlg.lib";
int e=14;
ring r=(complex,e,I),(x,y,z),dp;
poly f1=(x2+y2+z2-6)*(x-y)*(x-1);
poly f2=(x2+y2+z2-6)*(x-z)*(y-2);
poly f3=(x2+y2+z2-6)*(x-y)*(x-z)*(z-3);
ideal J=f1,f2,f3;
list p0=0.9999999999999999+I*0.0000000000000001,2,3+I*0.0000000000000001;
list p2=1,0.9999999999999998,2;
list p1=5+I,4.9999999999999998+I,5+I;
def D=NumLocalDim(J,p0,e);
==>
The Local Dimension:
0
def D=NumLocalDim(J,p1,e);
==>
The Local Dimension:
1
def D=NumLocalDim(J,p2,e);
==>
The Local Dimension:
2
```

D.5.9 numerDecom.lib

Todos/Issues:

- does not follow the naming convention
- syntax errors in examples
- no test suite

Library: NumDecom.lib

Purpose: Numerical Decomposition of Ideals

Overview: The library contains procedures to compute numerical irreducible decomposition, and numerical primary decomposition of an algebraic variety defined by a polynomial system. The use of the library requires to install Bertini ([@uref{http://www.nd.edu/~sommese/bertini}](http://www.nd.edu/~sommese/bertini)).

Author: Shawki AlRashed, rashed@mathematik.uni-kl.de; sh.shawki@yahoo.de

Procedures:

D.5.9.1 re2squ

Procedure from library `numerDecom.lib` (see [Section D.5.9 \[numerDecom.lib\], page 1458](#)).

Usage: `re2squ(ideal I);I ideal`

Return: ideal J defined by the polynomial system of the same number of polynomials and unknowns

Example:

```
LIB "numerDecom.lib";
ring r=0,(x,y,z),dp;
ideal I= x3+y4,z4+yx,xz+3x,x2y+z;
def D=re2squ(I);
setring D;
J;
```

D.5.9.2 UseBertini

Procedure from library `numerDecom.lib` (see [Section D.5.9 \[numerDecom.lib\], page 1458](#)).

Usage: `UseBertini(ideal H,string sv);`
H ideal, sv string of the variable of ring

Return: text file called input used in Bertini to compute the solution of the homotopy function H that existed in file input.text

Note: Need to define a start solution of H

Example:

```
LIB "numerDecom.lib";
ring r=0,(x,y,z),dp;
ideal I= x3+y4,z4+yx,xz+3x,x2y+z;
string sv=varstr(basering);
def A=UseBertini(I,sv);
```

D.5.9.3 Singular2bertini

Procedure from library `numerDecom.lib` (see [Section D.5.9 \[numerDecom.lib\], page 1458](#)).

Usage: `Singular2bertini(list L);` L a list

Return: text file called start

Note: adopting the list L to be as a start solution of the homotopy function in Bertini

Example:

```
LIB "numerDecom.lib";
ring r=(complex,16,I),(x,y,z),dp;
list L=list(1,2,3),list(4,5,6+I*2);
def D=Singular2bertini(L);
```

D.5.9.4 bertini2Singular

Procedure from library `numerDecom.lib` (see [Section D.5.9 \[numerDecom.lib\], page 1458](#)).

Usage: `bertini2Singular(string snp, int q);`
 snp string, q=nvars(basing) integer

Return: re list of the solutions of the homotopy function computed by Bertini

Example:

```
LIB "numerDecom.lib";
ring r = 0,(a,b,c),ds;
int q=nvars(basing);
def T=bertini2Singular("nonsingular_solutions",q);
re;
```

D.5.9.5 ReJunkUseHomo

Procedure from library `numerDecom.lib` (see [Section D.5.9 \[numerDecom.lib\], page 1458](#)).

Usage: `ReJunkUseHomo(ideal I, ideal L, list W, list w);`
 I ideal, L list of generic linear polynomials $\{l_1, \dots, l_i\}$, W list of a subset of the solution
 set of the generic slicing $V(L)$ with $V(J)$, w list of a point in $V(J)$

Return: t=1 if w on an i-dimensional component of $V(I)$,
 otherwise t=0. Where $i=\text{size}(L)$

Example:

```
LIB "numerDecom.lib";
ring r=(complex,16,I),(x,y,z),dp;
poly f1=(x2+y2+z2-6)*(x-y)*(x-1);
poly f2=(x2+y2+z2-6)*(x-z)*(y-2);
poly f3=(x2+y2+z2-6)*(x-y)*(x-z)*(z-3);
ideal J=f1,f2,f3;
poly l1=15x+16y+6z+17;
poly l2=2x+14y+4z+18;
ideal L=l1,l2;
list W1=list(0.5372775295412116,-0.7105339291010922,-2.2817700129167831+I*0),list(0.0,0.0,0.0);
list w=list(2,2,-131666666/10000000);
def D=ReJunkUseHomo(J,L,W1,w);
setring D;
t;
```

D.5.9.6 JuReTopDim

Procedure from library `numerDecom.lib` (see [Section D.5.9 \[numerDecom.lib\], page 1458](#)).

Return: $t=1$ if w on a d -dimensional component of $V(I)$, otherwise $t=0$.

Example:

```
LIB "numerDecom.lib";
ring r=(complex,16,I),(x,y,z),dp;
poly f1=(x2+y2+z2-6)*(x-y)*(x-1);
poly f2=(x2+y2+z2-6)*(x-z)*(y-2);
poly f3=(x2+y2+z2-6)*(x-y)*(x-z)*(z-3);
ideal J=f1,f2,f3;
list w=list(0.5372775295412116,-0.7105339291010922,-2.2817700129167831);
def D=JuReTopDim(J,w,2,2);
setring D;
t;
```

D.5.9.7 JuReZeroDim

Procedure from library `numerDecom.lib` (see [Section D.5.9 \[numerDecom.lib\], page 1458](#)).

Return: $t=1$ if w on a positive-dimensional component of $V(I)$, i.e w is not isolated point in $V(J)$

Example:

```
LIB "numerDecom.lib";
ring r=(complex,16,I),(x,y,z),dp;
poly f1=(x2+y2+z2-6)*(x-y)*(x-1);
poly f2=(x2+y2+z2-6)*(x-z)*(y-2);
poly f3=(x2+y2+z2-6)*(x-y)*(x-z)*(z-3);
ideal J=f1,f2,f3;
list w1=list(0.5372775295412116,-0.7105339291010922,-2.2817700129167831);
def D1=JuReZeroDim(J,w1,2);
setring D1;
t;
```

D.5.9.8 WitSupSet

Procedure from library `numerDecom.lib` (see [Section D.5.9 \[numerDecom.lib\], page 1458](#)).

Usage: `WitSupSet(ideal I);I ideal`

Return: list of Witness point Super Sets $W(i)$ for $i=1,\dots,\dim(V(I))$, L list of generic linear polynomials and $N(0)$ list of a polynomial system of the same number of polynomials and unknowns. // if $W(i) = x$, then $V(I)$ has no component of dimension i

Example:

```
LIB "numerDecom.lib";
ring r=0,(x,y,z),dp;
poly f1=(x2+y2+z2-6)*(x-y)*(x-1);
poly f2=(x2+y2+z2-6)*(x-z)*(y-2);
poly f3=(x2+y2+z2-6)*(x-y)*(x-z)*(z-3);
ideal I=f1,f2,f3;
def W=WitSupSet(I);
setring W;
```

```

W(2);
// witness point super set of a pure 2-dimensional component of V(I)
W(1);
// witness point super set of a pure 1-dimensional component of V(I)
W(0);
// witness point super set of a pure 0-dimensional component of V(I)
L;
// list of generic linear polynomials

```

D.5.9.9 WitSet

Procedure from library `numerDecom.lib` (see [Section D.5.9 \[numerDecom.lib\]](#), page 1458).

Usage: WitSet(ideal I); I ideal

Return: lists $W(0..d)$ of witness point sets of i -dimensional components of $V(J)$ for $i=0,...,d$ respectively, where d the dimension of $V(J)$, L list of generic linear polynomials

Note: if $W(i)=x$, then $V(J)$ has no component of dimension i

Example:

```

LIB "numerDecom.lib";
ring r=0,(x,y,z),dp;
poly f1=(x3+z)*(x2-y);
poly f2=(x3+y)*(x2-z);
poly f3=(x3+y)*(x3+z)*(z2-y);
ideal I=f1,f2,f3;
def W=WitSet(I);
setring W;
W(1);
// witness point set of a pure 1-dimensional component of V(I)
W(0);
// witness point set of a pure 0-dimensional component of V(I)
L;
// list of generic linear polynomials

```

D.5.9.10 NumIrrDecom

Procedure from library `numerDecom.lib` (see [Section D.5.9 \[numerDecom.lib\]](#), page 1458).

Return: $w(1),..., w(t)$ lists of irreducible witness point sets of irreducible components of $V(J)$

Example:

```

LIB "numerDecom.lib";
ring r=0,(x,y,z),dp;
poly f1=(x2+y2+z2-6)*(x-y)*(x-1);
poly f2=(x2+y2+z2-6)*(x-z)*(y-2);
poly f3=(x2+y2+z2-6)*(x-y)*(x-z)*(z-3);
ideal I=f1,f2,f3;
list W=NumIrrDecom(I);
==>
Dimension
0
Number of Components
1
Dimension

```

```

1
Number of Components
3
Dimension
2
Number of Components
1
def A(0)=W[1];
// corresponding 0-dimensional components
setring A(0);
w(1);
// corresponding 0-dimensional irreducible component
==> 0-Witness point set (one point)
def A(1)=W[2];
// corresponding 1-dimensional components
setring A(1);
w(1);
// corresponding 1-dimensional irreducible component
==> 1-Witness point set (one point)
w(2);
// corresponding 1-dimensional irreducible component
==> 1-Witness point set (one point)
w(3);
// corresponding 1-dimensional irreducible component
==> 1-Witness point set (one point)
def A(2)=W[3];
// corresponding 2-dimensional components
setring A(2);
w(1);
// corresponding 2-dimensional irreducible component
==> 1-Witness point set (two points)

```

D.5.9.11 defl

Procedure from library `numerDecom.lib` (see [Section D.5.9 \[numerDecom.lib\]](#), page 1458).

Usage: `defl(ideal I, int d);` I ideal, int d order of the deflation

Return: deflation ideal DI of I

Example:

```

LIB "numerDecom.lib";
ring r=0,(x,y,z),dp;
poly f1=z^2;
poly f2=z*(x^2+y);
ideal I=f1,f2;
def D=defl(I,1);
setring D;
DI;

```

D.5.9.12 NumPrimDecom

Procedure from library `numerDecom.lib` (see [Section D.5.9 \[numerDecom.lib\]](#), page 1458).

Usage: `NumPrimDecom(ideal I,int d);` I ideal, d order of the deflation

Return: lists of the numerical primary decomposition

Example:

```
LIB "numerDecom.lib";
ring r=0,(x,y),dp;
poly f1=yx;
poly f2=x2;
ideal I=f1,f2;
def W=NumPrimDecom(I,1);
setring W;
w(1);
==> 1-Witness point set (one point)
w(2);
==> 1-Witness point set (one point)
```

D.5.10 orbitparam.lib

Library: orbitparam.lib

Purpose: Parametrizing orbits of unipotent actions

Authors: J. Boehm, boehm at mathematik.uni-kl.de
S. Papadakis, papadakis at math.ist.utl.pt

Overview: This library implements the theorem of Chevalley-Rosenlicht as stated in Theorem 3.1.4 of [Corwin, Greenleaf]. Given a set of strictly upper triangular $n \times n$ matrices L_1, \dots, L_c which generate a Lie algebra as a vector space, and a vector v of size n , the function `parametrizeOrbit` constructs a parametrization of the orbit of v under the action of $\exp(\langle L_1, \dots, L_c \rangle)$.

To compute \exp of the Lie algebra elements corresponding to the parameters we require that the characteristic of the base field is zero or larger than n .

By determining the parameters from bottom to top this allows you to find an element in the orbit with (at least) as many zeros as the dimension of the orbit.

Note: Theorem 3.1.4 of [Corwin, Greenleaf] uses strictly lower triangular matrices.

References:

Laurence Corwin, Frederick P. Greenleaf: Representations of Nilpotent Lie Groups and their Applications: Volume 1, Part 1, Basic Theory and Examples, Cambridge University Press (2004).

Procedures:

D.5.10.1 tangentGens

Procedure from library `orbitparam.lib` (see [Section D.5.10 \[orbitparam.lib\]](#), page 1463).

Usage: `tangentGens(L,v)`; L list, v matrix.

Assume: L is a list of strictly upper triangular $n \times n$ matrices of same size. The vector space $\langle L \rangle$ generated by the elements of L should be closed under the Lie bracket.
 v is matrix of constants of size $n \times 1$.

Return: list, with four entries

- first entry is the dimension of the orbit of under the action of $\exp(\langle L \rangle)$
- second entry is a list generators of the tangent space of the orbit of v at v under the action of $\exp(\langle L \rangle)$. If the characteristic p of the ground field is positive, then n has to be smaller than p . The generators are elements of $\langle L \rangle$.
- third entry is the list of matrices with the coefficient to obtain the generators as a linear combination of the elements of L
- fourth entry is list of integers with entries in v which can be made zero by the action of $\exp(\langle L \rangle)$

Theory: We apply the theorem of Chevalley-Rosenlicht.

Example:

```
LIB "orbitparam.lib";
ring R = 0,(x),dp;
matrix L1[3][3] = 0,1,0, 0,0,0, 0,0,0;
matrix L2[3][3] = 0,0,1, 0,0,0, 0,0,0;
matrix L3[3][3] = 0,1,1, 0,0,1, 0,0,0;
list L = L1,L2,L3;
matrix v[3][1] = 1,2,3;
tangentGens(L,v);

```

D.5.10.2 matrixExp

Procedure from library `orbitparam.lib` (see [Section D.5.10 \[orbitparam.lib\], page 1463](#)).

Usage: `matrixExp(A)`; A matrix.

Assume: A is a nilpotent $n \times n$ matrix.
If the characteristic p of the ground field is positive, then n has to be smaller than p .

Return: matrix, `exp(A)`

Theory: We compute the power series, which terminates since A is nilpotent.

Example:

```

LIB "orbitparam.lib";
ring R = 0,(x),dp;
matrix A[4][4] = 0,0,1,0, 0,0,1,0, 0,0,0,0;
matrixExp(A);
↳ _[1,1]=1
↳ _[1,2]=0

↳ _[3,3]=1
↳ _[3,4]=0
↳ _[4,1]=0
↳ _[4,2]=0
↳ _[4,3]=0
↳ _[4,4]=1

```

D.5.10.3 matrixLog

Procedure from library `orbitparam.lib` (see [Section D.5.10 \[orbitparam.lib\], page 1463](#)).

Usage: `matrixLog(A)`; A matrix.

Assume: A-E is a nilpotent $n \times n$ matrix.
If the characteristic p of the ground field is positive, then n has to be smaller than p .

Return: matrix, `log(A)`

Theory: We compute the power series, which terminates since A-E is nilpotent.

Example:

```

LIB "orbitparam.lib";
ring R = 0,(s,t),dp;

```

```

matrix A[3][3] = 1,s,st/2, 0,1,t, 0,0,1;
matrixLog(A);
⇒ _[1,1]=0
⇒ _[1,2]=s
⇒ _[1,3]=0
⇒ _[2,1]=0
⇒ _[2,2]=0
⇒ _[2,3]=t
⇒ _[3,1]=0
⇒ _[3,2]=0
⇒ _[3,3]=0

```

D.5.10.4 parametrizeOrbit

Procedure from library `orbitparam.lib` (see [Section D.5.10 \[orbitparam.lib\]](#), page 1463).

Usage: `parametrizeOrbit(L,v)`; L list, v matrix.

Assume: L is a list of strictly upper triangular $n \times n$ matrices of same size. The vector space $\langle L \rangle$ generated by the elements of L should be closed under the Lie bracket.
v is matrix of constants of size $n \times 1$.
The basering has at least `size(L)` variables. However we will only use `tangentGens(L,v)[1]` many of them.

Return: list, with four entries
- int, dimension of the orbit
- matrix A over the basering giving a parametrization of the orbit of v under the action of $\exp(\langle L \rangle)$.
- list of integers, with the (row)-indices of entries which can be deleted by the action
- the variables of the parametrization to solve for

Theory: We apply the theorem of Chevalley-Rosenlicht. First we determine tangent space generators, then apply `matrixExp` to the generators, and finally take the product to obtain the parametrization.

Example:

```

LIB "orbitparam.lib";
ring R = 0,(t(1..3)),dp;
matrix L1[3][3] = 0,1,0, 0,0,0, 0,0,0;
matrix L2[3][3] = 0,0,1, 0,0,0, 0,0,0;
matrix L3[3][3] = 0,1,1, 0,0,1, 0,0,0;
list L = L1,L2,L3;
matrix v[3][1] = 1,2,3;
parametrizeOrbit(L,v);
⇒ [1]:
⇒ 2
⇒ [2]:
⇒ _[1,1]=1/6*t(1)^2+5/3*t(1)+t(2)+1
⇒ _[2,1]=t(1)+2
⇒ _[3,1]=3
⇒ [3]:
⇒ [1]:
⇒ 2
⇒ [2]:
⇒ 1

```

```

D.5.10.5 maxZeros

Procedure from library `orbitparam.lib` (see [Section D.5.10 \[orbitparam.lib\]](#), page 1463).

Usage: `maxZeros(L,v)`; L list, v matrix.

Assume: L is a list of strictly upper triangular $n \times n$ matrices of same size. The vector space $\langle L \rangle$ generated by the elements of L should be closed under the Lie bracket.

v is matrix of constants of size $n \times 1$.

The basering has at least $\text{size}(L)$ variables. However we will only use $\text{tangentGens}(L,v)[1]$ many of them.

Return: matrix of constants over the basering giving an element in the orbit of v under the action of $\exp(\langle L \rangle)$ with (at least) as many zeros as the dimension of the orbit.

Theory: We apply `parametrizeOrbit` to obtain a parametrization of the orbit according to the theorem of Chevalley-Rosenlicht. By determining the parameters from bottom to top we find an element in the orbit with (at least) as many zeros as the dimension of the orbit.

Example:

```

LIB "orbitparam.lib";
ring R = 0,(x),dp;
matrix L1[3][3] = 0,1,0, 0,0,0, 0,0,0;
matrix L2[3][3] = 0,0,1, 0,0,0, 0,0,0;

```

```

matrix L3[3][3] = 0,1,1, 0,0,1, 0,0,0;
list L = L1,L2,L3;
matrix v[3][1] = 1,2,3;
maxZeros(L,v);
↳ _[1,1]=0
↳ _[2,1]=0
↳ _[3,1]=3
ring R1 = 0,(x),dp;
matrix L1[4][4] = 0,1,0,0, 0,0,0,0, 0,0,0,1, 0,0,0,0;
matrix L2[4][4] = 0,0,1,0, 0,0,0,1, 0,0,0,0, 0,0,0,0;
list L = L1,L2;
matrix v[4][1] = 1,2,3,4;
maxZeros(L,v);
↳ _[1,1]=-1/2
↳ _[2,1]=0
↳ _[3,1]=0
↳ _[4,1]=4

```

D.5.11 paraplancurves.lib

Library: paraplancurves.lib

Purpose: Rational parametrization of rational plane curves

Authors: J. Boehm, boehm at mathematik.uni-kl.de
W. Decker, decker at mathematik.uni-kl.de
S. Laplagne, slaplagn at dm.uba.ar
F. Seelisch, seelisch at mathematik.uni-kl.de

Overview: Suppose $C = \{f(x,y,z)=0\}$ is a rational plane curve, where f is homogeneous of degree n with coefficients in \mathbb{Q} and absolutely irreducible (these conditions are checked automatically.)

After a first step, realized by a projective automorphism in the procedure `adjointIdeal`, C satisfies:

- C does not have singularities at infinity $z=0$.
- C does not contain the point $(0:1:0)$ (that is, the dehomogenization of f with respect to z is monic as a polynomial in y).

Considering C in the chart $z > 0$, the algorithm regards x as transcendental and y as algebraic and computes an integral basis in $C(x)[y]$ of the integral closure of $C[x]$ in $C(x,y)$ using the normalization algorithm from [Section D.4.23 \[normal.lib\], page 1185](#): see [Section D.4.12 \[integralbasis.lib\], page 1116](#). In a future edition of the library, also van Hoeij's algorithm for computing the integral basis will be available.

From the integral basis, the adjoint ideal is obtained by linear algebra. Alternatively, the algorithm starts with a local analysis of the singular locus of C . Then, for each primary component of the singular locus which does not correspond to ordinary multiple points or cusps, the integral basis algorithm is applied separately. The ordinary multiple points and cusps, in turn, are addressed by a straightforward direct algorithm. The adjoint ideal is obtained by intersecting all ideals obtained locally. The local variant of the algorithm is used by default.

The linear system corresponding to the adjoint ideal maps the curve birationally to a rational normal curve in \mathbb{P}^{n-2} .

Iterating the anticanonical map, the algorithm projects the rational normal curve to \mathbb{P}^1 for n odd resp. to a conic C^2 in \mathbb{P}^2 for n even.

In case n is even, the algorithm tests whether there is a rational point on C^2 and if so gives a parametrization of C^2 which is defined over \mathbb{Q} . Otherwise, the parametrization given is defined over a quadratic field extension of \mathbb{Q} .

By inverting the birational map of C to \mathbb{P}^1 resp. to C^2 , a parametrization of C is obtained (defined over \mathbb{Q} or the quadratic field extension).

Procedures:

D.5.11.1 adjointIdeal

Procedure from library `paraplanecurves.lib` (see [Section D.5.11 \[paraplanecurves.lib\]](#), [page 1468](#)).

Usage: `adjointIdeal(f [, choices]);` f polynomial in three variables, `choices` optional list consisting of one integer or of one string or of one integer followed by one string.

Optional integer can be:

- 1: compute integral basis via normalization.
- 2: make local analysis of singularities first and apply normalization separately.
- 3: normalization via ideal quotient.
- 4: normalization via local ideal quotient.

The default is 2.

Optional string may contain substrings:

- `rattestyes` -> causes error message if curve is not rational.
- `firstchecksdone` -> prevents that check of assumptions will be done more than once.

Assume: The basering must be a polynomial ring in three variables, say x, y, z , with coefficients in \mathbb{Q} .

The polynomial f must be homogeneous and absolutely irreducible.

All these conditions will be checked automatically.

Return: ideal, the adjoint ideal of the curve defined by f .

Theory: Considering C in the chart $z \neq 0$, the algorithm regards x as transcendental and y as algebraic and computes an integral basis in $C(x)[y]$ of the integral closure of $C[x]$ in $C(x, y)$ using the normalization algorithm from [Section D.4.23 \[normal.lib\]](#), [page 1185](#): see [Section D.4.12 \[integralbasis.lib\]](#), [page 1116](#). In a future edition of the library, also van Hoeij's algorithm for computing the integral basis will be available. From the integral basis, the adjoint ideal is obtained by linear algebra. Alternatively,

the algorithm starts with a local analysis of the singular locus of C . Then, for each primary component of the singular locus which does not correspond to ordinary multiple points or cusps, the integral basis algorithm is applied separately. The ordinary multiple points and cusps, in turn, are addressed by a straightforward direct algorithm. The adjoint ideal is obtained by intersecting all ideals obtained locally. The local variant of the algorithm is used by default.

Example:

```
LIB "paraplanecurves.lib";
ring R = 0,(x,y,z),dp;
poly f = y^8-x^3*(z+x)^5;
adjointIdeal(f);
↪ _[1]=y6
↪ _[2]=xy5+y5z
↪ _[3]=x2y4+xy4z
↪ _[4]=x3y3+2x2y3z+xy3z2
↪ _[5]=x4y2+3x3y2z+3x2y2z2+xy2z3
↪ _[6]=x5y+3x4yz+3x3yz2+x2yz3
↪ _[7]=x6+4x5z+6x4z2+4x3z3+x2z4
```

D.5.11.2 invertBirMap

Procedure from library `paraplanecurves.lib` (see [Section D.5.11 \[paraplanecurves.lib\]](#), [page 1468](#)).

Usage: `invertBirMap(phi, I);` phi ideal, I ideal

Assume: The ideal phi in the basering R represents a birational map of the variety given by the ideal I in R to its image in projective space $P = \mathbb{P}^{(\text{size}(\text{phi})-1)}$.

Note: The procedure might fail or give a wrong output if phi does not define a birational map.

Return: ring, the coordinate ring of P , with an ideal named J and an ideal named psi.
 The ideal J defines the image of phi.
 The ideal psi gives the inverse of phi.
 Note that the entries of psi should be considered as representatives of classes in the quotient ring R/J .

Theory: We compute the ideal $I(G)$ in $R^{**}S$ of the graph G of phi.
 The ideal J is given by the intersection of $I(G)$ with S .
 The map psi is given by a relation mod J of those relations in $I(G)$ which are linear in the variables of R.

Example:

```
LIB "paraplanecurves.lib";
ring R = 0,(x,y,z),dp;
poly f = y^8-x^3*(z+x)^5;
ideal adj = adjointIdeal(f);
def Rn = invertBirMap(adj,ideal(f));
↪ // 'invertBirMap' created a ring together with two ideals J and psi.
↪ // Supposing you typed, say, def RPn = invertBirMap(phi,I);
```

```

⇒ // you may access the ideals by typing
⇒ //      setring RPn; J; psi;
setring(Rn);
J;
⇒ J[1]=y(5)*y(6)-y(4)*y(7)
⇒ J[2]=y(4)*y(6)-y(3)*y(7)
⇒ J[3]=y(2)*y(6)-y(1)*y(7)
⇒ J[4]=y(4)*y(5)-y(2)*y(7)
⇒ J[5]=y(3)*y(5)-y(1)*y(7)
⇒ J[6]=y(1)*y(5)-y(7)^2
⇒ J[7]=y(4)^2-y(1)*y(7)
⇒ J[8]=y(3)*y(4)-y(1)*y(6)
⇒ J[9]=y(2)*y(4)-y(7)^2
⇒ J[10]=y(1)*y(4)-y(6)*y(7)
⇒ J[11]=y(2)*y(3)-y(6)*y(7)
⇒ J[12]=y(1)*y(3)-y(6)^2
⇒ J[13]=y(2)^2-y(5)*y(7)
⇒ J[14]=y(1)*y(2)-y(4)*y(7)
⇒ J[15]=y(1)^2-y(3)*y(7)
⇒ J[16]=y(1)*y(6)^2-y(3)^2*y(7)
⇒ J[17]=y(6)^4-y(3)^3*y(7)
psi;
⇒ psi[1]=-y(6)^2
⇒ psi[2]=-y(4)*y(7)
⇒ psi[3]=y(6)^2-y(5)*y(7)

```

D.5.11.3 paraPlaneCurve

Procedure from library `paraplanecurves.lib` (see [Section D.5.11 \[paraplanecurves.lib\]](#), [page 1468](#)).

- Usage:** `paraPlaneCurve(f [, s]);` `f` poly, `s` optional string
optional string `s` can be:
'normal': compute integral basis via normalization.
'local': make local analysis of singularities first and apply normalization separately.
The default is 2.
- Assume:** The basering must be a polynomial ring in three variables, say x, y, z , with coefficients in \mathbb{Q} .
The polynomial f must be homogeneous and absolutely irreducible.
The curve $C = \{f = 0\}$ must be rational, i.e., have geometric genus 0 (see [Section D.4.23.7 \[genus\]](#), [page 1204](#)).
These conditions will be checked automatically.
- Return:** ring with an ideal `PARA` which contains a rational parametrization of the rational plane curve given by f ; the ground field of the returned polynomial ring is either \mathbb{Q} or some algebraic extension $\mathbb{Q}(a)$; `PARA` consists of three generators that parametrize the three coordinates of the rational curve
- Theory:** After a first step, realized by a projective automorphism in the procedure `adjointIdeal`, C satisfies:
- C does not have singularities at infinity $z=0$.
- C does not contain the point $(0:1:0)$ (that is, the dehomogenization of f with respect

to z is monic as a polynomial in y).

Considering C in the chart $z \neq 0$, the algorithm regards x as transcendental and y as algebraic and computes an integral basis in $C(x)[y]$ of the integral closure of $C[x]$ in $C(x,y)$ using the normalization algorithm from [Section D.4.23 \[normal_lib\], page 1185](#): see [Section D.4.12 \[integralbasis_lib\], page 1116](#). In a future edition of the library, also van Hoeij's algorithm for computing the integral basis will be available.

From the integral basis, the adjoint ideal is obtained by linear algebra. Alternatively, the algorithm starts with a local analysis of the singular locus of C . Then, for each primary component of the singular locus which does not correspond to ordinary multiple points or cusps, the integral basis algorithm is applied separately. The ordinary multiple points and cusps, in turn, are addressed by a straightforward direct algorithm. The adjoint ideal is obtained by intersecting all ideals obtained locally. The local variant of the algorithm is used by default.

The linear system corresponding to the adjoint ideal maps the curve birationally to a rational normal curve in $P^{(n-2)}$.

Iterating the anticanonical map, the algorithm projects the rational normal curve to $PP1$ for n odd resp. to a conic $C2$ in $PP2$ for n even.

In case n is even, the algorithm tests whether there is a rational point on $C2$ and if so gives a parametrization of $C2$ which is defined over Q . Otherwise the parametrization is defined over a quadratic field extension of Q .

By inverting the birational map of C to $PP1$ resp. to $C2$, a parametrization of C is obtained (defined over Q or the quadratic field extension).

Example:

```
LIB "paraplanecurves.lib";
ring R = 0,(x,y,z),dp;
poly f1 = 1/2*x^5+x^2*y*z^2+x^3*y*z+1/2*x*y^2*z^2-2*x*y^3*z+y^5;
def Rp1 = paraPlaneCurve(f1);
⇒ // 'paraPlaneCurve' created a ring together with an ideal PARA.
⇒ // Supposing you typed, say, def RP1 = paraPlaneCurve(f);
⇒ // you may access the ideal by typing
⇒ //      setring RP1; PARA;
setring Rp1;
PARA;
⇒ PARA[1]=-4s4t+2s3t2
⇒ PARA[2]=2s2t3-st4
⇒ PARA[3]=4s5-t5
setring R;
poly f2 = x6+3x4y2+3x2y4+y6-4x4z2-34x3yz2-7x2y2z2+12xy3z2+6y4z2;
f2 = f2+36x2z4+36xyz4+9y2z4;
def Rp2 = paraPlaneCurve(f2);
⇒ // 'paraPlaneCurve' created a ring together with an ideal PARA.
⇒ // Supposing you typed, say, def RP1 = paraPlaneCurve(f);
⇒ // you may access the ideal by typing
⇒ //      setring RP1; PARA;
setring Rp2;
PARA;

D.5.11.4 rncAntiCanonicalMap

Procedure from library `paraplanecurves.lib` (see [Section D.5.11 \[paraplanecurves.lib\]](#), [page 1468](#)).

Usage: `rncAntiCanonicalMap(I);` I ideal

Assume: I is a homogeneous ideal in the basering
defining a rational normal curve C in \mathbb{P}^n .

Note: The procedure will fail or give a wrong output if I is not the ideal of a rational normal curve.

Return: ideal defining the anticanonical map $C \rightarrow \mathbb{P}^{n-2}$.
Note that the entries of the ideal should be considered as representatives of elements in R/I , where R is the basering.

Theory: The anti-canonical map of a rational normal curve
maps C isomorphically to a rational normal curve in \mathbb{P}^{n-2} .

Example:

```

LIB "paraplanecurves.lib";
ring R = 0,(x,y,z),dp;
poly f = y^8-x^3*(z+x)^5;
ideal adj = adjointIdeal(f);
def Rn = mapToRatNormCurve(f,adj);
⇒ //'mapToRatNorm' created a ring together with an ideal RNC.
⇒ // Supposing you typed, say, def RPn = mapToRatNorm(f,AI);
⇒ // you may access the ideal by typing
⇒ //      setring RPn; RNC;
setring(Rn);
RNC;
⇒ RNC[1]=y(5)*y(6)-y(4)*y(7)
⇒ RNC[2]=y(4)*y(6)-y(3)*y(7)
⇒ RNC[3]=y(2)*y(6)-y(1)*y(7)
⇒ RNC[4]=y(4)*y(5)-y(2)*y(7)
⇒ RNC[5]=y(3)*y(5)-y(1)*y(7)
⇒ RNC[6]=y(1)*y(5)-y(7)^2
⇒ RNC[7]=y(4)^2-y(1)*y(7)
⇒ RNC[8]=y(3)*y(4)-y(1)*y(6)
⇒ RNC[9]=y(2)*y(4)-y(1)*y(5)
⇒ RNC[10]=y(1)*y(4)-y(6)*y(7)
⇒ RNC[11]=y(2)*y(3)-y(6)*y(7)
⇒ RNC[12]=y(1)*y(3)-y(6)^2
⇒ RNC[13]=y(2)^2-y(5)*y(7)

```

```

⇒ RNC[14]=y(1)*y(2)-y(4)*y(7)
⇒ RNC[15]=y(1)^2-y(3)*y(7)
⇒ RNC[16]=y(1)*y(6)^2-y(3)^2*y(7)
⇒ RNC[17]=y(6)^4-y(3)^3*y(7)
rncAntiCanonicalMap(RNC);
⇒ _[1]=y(1)
⇒ _[2]=-y(2)
⇒ _[3]=-y(5)
⇒ _[4]=-y(4)
⇒ _[5]=-y(7)

```

D.5.11.5 rationalPointConic

Procedure from library `paraplanecurves.lib` (see [Section D.5.11 \[paraplanecurves.lib\]](#), [page 1468](#)).

Usage: `rationalPointConic(p);` p poly

Assume: assumes that p is an irreducible quadratic polynomial in the first three ring variables; ground field is expected to be \mathbb{Q} .

Return: The method finds a point on the given conic. There are two possibilities:

- 1) There is a rational point on the curve.
- 2) There is no rational point on the curve.

In the second case, the method creates a modification of the current basering which is a polynomial ring over some quadratic field extension $\mathbb{Q}(a)$ of \mathbb{Q} . Apart from the replacement of \mathbb{Q} by $\mathbb{Q}(a)$, the new polynomial ring, R say, is the same as the original basering. (In the first case, R is identical with the basering.) In both cases, the method will then define a (1×3) matrix named 'point' which lives in R and which contains the coordinates of the desired point on q .

Finally, the method returns the ring R (which will in the 1st case be the original base ring).

Example:

```

LIB "paraplanecurves.lib";
ring R = 0, (x,y,z), dp;
system("random", 4711);
poly p = x^2 + 2*y^2 + 5*z^2 - 4*x*y + 3*x*z + 17*y*z;
def S = rationalPointConic(p); // quadratic field extension,
// minpoly = a^2 - 2
testPointConic(p, S);
⇒ conic: x2-4xy+2y2+3xz+17yz+5z2
⇒ point: (-1/4a), (-1/4a+1/4), 0
⇒ minpoly: (a2-2)
⇒ 1
setring R;
p = x^2 - 1857669520 * y^2 + 86709575222179747132487270400 * z^2;
S = rationalPointConic(p); // same as current basering,
// no extension needed
testPointConic(p, S);
⇒ conic: x2-1857669520y2+86709575222179747132487270400z2
⇒ point: 819398304609269135405871919690911280, 4998995645707055256041604614\
16220, 73117135886813712113057
⇒ 1

```

D.5.11.6 mapToRatNormCurve

Procedure from library `paraplanecurves.lib` (see [Section D.5.11 \[paraplanecurves.lib\]](#), page 1468).

Usage: `mapToRatNormCurve(f, AI);` f polynomial, AI ideal

Assume: The polynomial f is homogeneous in three variables and absolutely irreducible.
The plane curve C defined by f is rational.
The ideal AI is the adjoint ideal of C .

Return: ring with an ideal RNC .

Example:

```
LIB "paraplanecurves.lib";
ring R = 0,(x,y,z),dp;
poly f = y^8-x^3*(z+x)^5;
ideal adj = adjointIdeal(f);
def Rn = mapToRatNormCurve(f,adj);
⇒ //'mapToRatNorm' created a ring together with an ideal RNC.
⇒ // Supposing you typed, say, def RPn = mapToRatNorm(f,AI);
⇒ // you may access the ideal by typing
⇒ //      setring RPn; RNC;
setring(Rn);
RNC;
⇒ RNC[1]=y(5)*y(6)-y(4)*y(7)
⇒ RNC[2]=y(4)*y(6)-y(3)*y(7)
⇒ RNC[3]=y(2)*y(6)-y(1)*y(7)
⇒ RNC[4]=y(4)*y(5)-y(2)*y(7)
⇒ RNC[5]=y(3)*y(5)-y(1)*y(7)
⇒ RNC[6]=y(1)*y(5)-y(7)^2
⇒ RNC[7]=y(4)^2-y(1)*y(7)
⇒ RNC[8]=y(3)*y(4)-y(1)*y(6)
⇒ RNC[9]=y(2)*y(4)-y(1)*y(5)
⇒ RNC[10]=y(1)*y(4)-y(6)*y(7)
⇒ RNC[11]=y(2)*y(3)-y(6)*y(7)
⇒ RNC[12]=y(1)*y(3)-y(6)^2
⇒ RNC[13]=y(2)^2-y(5)*y(7)
⇒ RNC[14]=y(1)*y(2)-y(4)*y(7)
⇒ RNC[15]=y(1)^2-y(3)*y(7)
⇒ RNC[16]=y(1)*y(6)^2-y(3)^2*y(7)
⇒ RNC[17]=y(6)^4-y(3)^3*y(7)
```

D.5.11.7 rncItProjOdd

Procedure from library `paraplanecurves.lib` (see [Section D.5.11 \[paraplanecurves.lib\]](#), page 1468).

Usage: `rncItProjOdd(I);` I ideal

Assume: I is a homogeneous ideal in the basering with $n+1$ variables defining a rational normal curve C in PP^n with n odd.

Note: The procedure will fail or give a wrong output if I is not the ideal of a rational normal curve. It will test whether n is odd.

Return: ideal PHI defining an isomorphic projection of C to PP^1 .
Note that the entries of PHI should be considered as representatives of elements in R/I , where R is the basering.

Theory: We iterate the procedure [Section D.5.11.4 \[rncAntiCanonicalMap\]](#), page 1473 to obtain PHI.

Example:

```
LIB "paraplanecurves.lib";
ring R = 0,(x,y,z),dp;
poly f = -x7-10x5y2-10x4y3-3x3y4+8x2y5+7xy6+11y7+3x6+10x5y +30x4y2
+26x3y3-13x2y4-29xy5-33y6-3x5-20x4y-33x3y2-8x2y3+37xy4+33y5
+x4+10x3y+13x2y2-15xy3-11y4;
f = homog(f,z);
ideal adj = adjointIdeal(f);
def Rn = mapToRatNormCurve(f,adj);
⇒ //'mapToRatNorm' created a ring together with an ideal RNC.
⇒ // Supposing you typed, say, def RPn = mapToRatNorm(f,AI);
⇒ // you may access the ideal by typing
⇒ //      setring RPn; RNC;
setring(Rn);
RNC;
⇒ RNC[1]=y(4)*y(5)-y(3)*y(6)
⇒ RNC[2]=y(2)*y(5)-y(1)*y(6)
⇒ RNC[3]=y(4)^2-y(2)*y(6)
⇒ RNC[4]=y(3)*y(4)-y(1)*y(6)
⇒ RNC[5]=11*y(1)*y(4)+7*y(2)*y(4)+8*y(1)*y(6)-3*y(2)*y(6)-10*y(3)*y(6)-10*y\
(4)*y(6)-y(6)^2
⇒ RNC[6]=y(3)^2-y(1)*y(5)
⇒ RNC[7]=11*y(2)*y(3)+7*y(2)*y(4)+8*y(1)*y(6)-3*y(2)*y(6)-10*y(3)*y(6)-10*y\
(4)*y(6)-y(6)^2
⇒ RNC[8]=11*y(1)*y(3)+7*y(1)*y(4)+8*y(1)*y(5)-10*y(3)*y(5)-3*y(1)*y(6)-10*y\
(3)*y(6)-y(5)*y(6)
⇒ RNC[9]=121*y(1)*y(2)+77*y(2)^2-89*y(2)*y(4)-174*y(1)*y(6)-86*y(2)*y(6)+80\
*y(3)*y(6)+69*y(4)*y(6)+8*y(6)^2
⇒ RNC[10]=1331*y(1)^2-539*y(2)^2+1246*y(2)*y(4)-1914*y(1)*y(5)+880*y(3)*y(5\
)+984*y(1)*y(6)+335*y(2)*y(6)-691*y(3)*y(6)-1373*y(4)*y(6)+88*y(5)*y(6)-1\
45*y(6)^2
rncItProjOdd(RNC);
⇒ _[1]=121*y(3)+77*y(4)
⇒ _[2]=-11*y(5)-7*y(6)
```

See also: [Section D.5.11.8 \[rncItProjEven\]](#), page 1476.

D.5.11.8 rncItProjEven

Procedure from library `paraplanecurves.lib` (see [Section D.5.11 \[paraplanecurves.lib\]](#), page 1468).

Usage: `rncItProjEven(I); I ideal`

Assume: I is a homogeneous ideal in the basering with $n+1$ variables defining a rational normal curve C in PP^n with n even.

Note: The procedure will fail or give a wrong output if I is not the ideal of a rational normal curve. It will test whether n is odd.

- Return:** ring with an ideal CONIC defining a conic C2 in PP^2 .
 In addition, an ideal PHI in the basering defining an isomorphic projection of C to C2 will be exported.
 Note that the entries of PHI should be considered as representatives of elements in R/I , where R is the basering.
- Theory:** We iterate the procedure [Section D.5.11.4 \[rncAntiCanonicalMap\]](#), page 1473 to obtain PHI.

Example:

```
LIB "paraplanecurves.lib";
ring R = 0,(x,y,z),dp;
poly f = y^8-x^3*(z+x)^5;
ideal adj = adjointIdeal(f);
def Rn = mapToRatNormCurve(f,adj);
⇨ //'mapToRatNorm' created a ring together with an ideal RNC.
⇨ // Supposing you typed, say, def RPn = mapToRatNorm(f,AI);
⇨ // you may access the ideal by typing
⇨ //      setring RPn; RNC;
setring(Rn);
RNC;
⇨ RNC[1]=y(5)*y(6)-y(4)*y(7)
⇨ RNC[2]=y(4)*y(6)-y(3)*y(7)
⇨ RNC[3]=y(2)*y(6)-y(1)*y(7)
⇨ RNC[4]=y(4)*y(5)-y(2)*y(7)
⇨ RNC[5]=y(3)*y(5)-y(1)*y(7)
⇨ RNC[6]=y(1)*y(5)-y(7)^2
⇨ RNC[7]=y(4)^2-y(1)*y(7)
⇨ RNC[8]=y(3)*y(4)-y(1)*y(6)
⇨ RNC[9]=y(2)*y(4)-y(1)*y(5)
⇨ RNC[10]=y(1)*y(4)-y(6)*y(7)
⇨ RNC[11]=y(2)*y(3)-y(6)*y(7)
⇨ RNC[12]=y(1)*y(3)-y(6)^2
⇨ RNC[13]=y(2)^2-y(5)*y(7)
⇨ RNC[14]=y(1)*y(2)-y(4)*y(7)
⇨ RNC[15]=y(1)^2-y(3)*y(7)
⇨ RNC[16]=y(1)*y(6)^2-y(3)^2*y(7)
⇨ RNC[17]=y(6)^4-y(3)^3*y(7)
def Rc = rncItProjEven(RNC);
PHI;
⇨ PHI[1]=-y(7)
⇨ PHI[2]=-y(2)
⇨ PHI[3]=-y(5)
setring Rc;
CONIC;
⇨ y(2)^2-y(1)*y(3)
```

See also: [Section D.5.11.7 \[rncItProjOdd\]](#), page 1475.

D.5.11.9 paraConic

Procedure from library `paraplanecurves.lib` (see [Section D.5.11 \[paraplanecurves.lib\]](#), page 1468).

Usage: `paraConic(q); q poly`

Assume: The basering must be a polynomial ring in three variables with coefficients in \mathbb{Q} . The polynomial q must be homogeneous of degree 2 and absolutely irreducible.

Note: The procedure might fail or give a wrong output if the assumptions do not hold.

Return: ring with an ideal PARACONIC. The ring should be considered as the homogeneous coordinate ring of \mathbb{P}^1 , the ideal defines a rational parametrization $\mathbb{P}^1 \rightarrow C2 = \{q=0\}$.

Theory: We compute a point on $C2$ via [Section D.5.11.5 \[rationalPointConic\], page 1474](#). The pencil of lines through this point projects $C2$ birationally to \mathbb{P}^1 . Inverting the projection gives the result.

Example:

```
LIB "paraplanecurves.lib";
ring R = 0,(x,y,z),dp;
poly f = y^8-x^3*(z+x)^5;
ideal adj = adjointIdeal(f);
def Rn = invertBirMap(adj,ideal(f));
⇒ // 'invertBirMap' created a ring together with two ideals J and psi.
⇒ // Supposing you typed, say, def RPn = invertBirMap(phi,I);
⇒ // you may access the ideals by typing
⇒ //      setring RPn; J; psi;
setring(Rn);
J;
⇒ J[1]=y(5)*y(6)-y(4)*y(7)
⇒ J[2]=y(4)*y(6)-y(3)*y(7)
⇒ J[3]=y(2)*y(6)-y(1)*y(7)
⇒ J[4]=y(4)*y(5)-y(2)*y(7)
⇒ J[5]=y(3)*y(5)-y(1)*y(7)
⇒ J[6]=y(1)*y(5)-y(7)^2
⇒ J[7]=y(4)^2-y(1)*y(7)
⇒ J[8]=y(3)*y(4)-y(1)*y(6)
⇒ J[9]=y(2)*y(4)-y(7)^2
⇒ J[10]=y(1)*y(4)-y(6)*y(7)
⇒ J[11]=y(2)*y(3)-y(6)*y(7)
⇒ J[12]=y(1)*y(3)-y(6)^2
⇒ J[13]=y(2)^2-y(5)*y(7)
⇒ J[14]=y(1)*y(2)-y(4)*y(7)
⇒ J[15]=y(1)^2-y(3)*y(7)
⇒ J[16]=y(1)*y(6)^2-y(3)^2*y(7)
⇒ J[17]=y(6)^4-y(3)^3*y(7)
def Rc = rncItProjEven(J);
PHI;
⇒ PHI[1]=-y(7)
⇒ PHI[2]=-y(2)
⇒ PHI[3]=-y(5)
setring Rc;
CONIC;
⇒ y(2)^2-y(1)*y(3)
def RPc = paraConic(CONIC);
⇒ // 'paraConic' created a ring together with an ideal RNC.
⇒ // Supposing you typed, say, def RP1 = paraConic(q);
⇒ // you may access the ideal by typing
```

```

↳ //      setring RP1; PARACONIC;
setring RPc;
PARACONIC;
↳ PARACONIC[1]=s2
↳ PARACONIC[2]=st
↳ PARACONIC[3]=t2

```

See also: [Section D.5.11.5 \[rationalPointConic\]](#), page 1474.

D.5.11.10 testParametrization

Procedure from library `paraplanecurves.lib` (see [Section D.5.11 \[paraplanecurves.lib\]](#), page 1468).

Usage: `testParametrization(f, rTT);` f poly, rTT ring

Assume: The assumptions on the basering and the polynomial f are as required by [Section D.5.11.3 \[paraPlaneCurve\]](#), page 1471. The ring rTT has two variables and contains an ideal $PARA$ (such as the ring obtained by applying [Section D.5.11.3 \[paraPlaneCurve\]](#), page 1471 to f).

Return: int which is 1 if $PARA$ defines a parametrization of the curve $\{f=0\}$ and 0, otherwise.

Theory: We compute the polynomial defining the image of $PARA$ and compare it with f .

Example:

```

LIB "paraplanecurves.lib";
ring R = 0,(x,y,z),dp;
poly f = y^8-x^3*(z+x)^5;
def RP1 = paraPlaneCurve(f);
↳ // 'paraPlaneCurve' created a ring together with an ideal PARA.
↳ // Supposing you typed, say, def RP1 = paraPlaneCurve(f);
↳ // you may access the ideal by typing
↳ //      setring RP1; PARA;
testParametrization(f, RP1);
↳ 1

```

D.5.11.11 testPointConic

Procedure from library `paraplanecurves.lib` (see [Section D.5.11 \[paraplanecurves.lib\]](#), page 1468).

Usage: `testPointConic(p, r);` p poly, r ring

Assume: assumes that p is a homogeneous quadratic polynomial in the first three ring variables of the current basering;
Assumes that there is a (1×3) matrix named 'point' in r with entries from the ground field of r .

Return: returns 1 iff the point named 'point', residing in r , lies on the conic given by p ; 0 otherwise

Note: This method temporarily changes the basering to r . Afterwards, the basering will be the same as before.

Example:

```

LIB "paraplanecurves.lib";
ring R = 0, (x,y,z), dp;
system("random", 4711);
poly p = x^2 + 2*y^2 + 5*z^2 - 4*x*y + 3*x*z + 17*y*z;
def S = rationalPointConic(p);
if (testPointConic(p, S) == 1)
  ↳ conic: x2-4xy+2y2+3xz+17yz+5z2
  ↳ point: (-1/4a), (-1/4a+1/4), 0
  ↳ minpoly: (a2-2)
  { "point lies on conic"; }
  ↳ point lies on conic
else
  { "point does not lie on conic"; }

```

D.5.12 resbinomial.lib

Todos/Issues:

formatting is inappropriate

avoid export

bad names(or should be static): identifyvars, elimrep, convertdata, lcmofall, genoutput, salida, iniD, reslist, sumlist, dividelist, createlist

Library: resbinomial.lib

Purpose: Combinatorial algorithm of resolution of singularities of binomial ideals in arbitrary characteristic. Binomial resolution algorithm of Blanco

Authors: R. Blanco, mariarocio.blanco@uclm.es,
G. Pfister, pfister@mathematik.uni-kl.de

Procedures:

D.5.12.1 BINresol

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: BINresol(J); J ideal

Return: E-resolution of singularities of a binomial ideal J in terms of the affine charts, see example

Example:

```

LIB "resbinomial.lib";
ring r = 0,(x(1..2)),dp;
ideal J=x(1)^2-x(2)^3;
list B=BINresol(J);
B[1]; // list of final charts
↳ [1]:
↳ // coefficients: QQ
↳ // number of vars : 2
↳ //      block 1 : ordering dp
↳ //      : names y(1) y(2)
↳ //      block 2 : ordering C
↳ [2]:
↳ // coefficients: QQ

```

```

⇒ // number of vars : 2
⇒ //      block 1 : ordering dp

D.5.12.2 Eresol

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: Eresol(J); J ideal

Return: The E-resolution of singularities of J in terms of the affine charts, see example

Example:

```

LIB "resbinomial.lib";
ring r = 0,(x(1..2)),dp;
ideal J=x(1)^2-x(2)^3;
list L=Eresol(J);
"Please press return after each break point to see the next element of the output list"
⇒ Please press return after each break point to see the next element of the\
   output list
L[1][1]; // information of the first chart, L[1] list of charts
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 0
⇒ [3]:

```

```

⇒ [10]:
⇒      empty list
⇒ [11]:
⇒      empty list
~;
⇒
⇒ -- break point in ./examples/Eresol.sing --

```

D.5.12.3 determinecenter

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `determinecenter(Coef,expJ,c,n,Y,a,listmb,flag,control3,Hhist);` Coef, expJ, listmb, flag lists, c number, n, Y, control3 integers, a, Hhist intvec

Compute: next center of blowing up and related information, see example

Return: several lists defining the center and related information

Example:

```

LIB "resbinomial.lib";
ring r = 0,(x(1..4)),dp;

```

```

list flag=identifyvar();
ideal J=x(1)^2-x(2)^2*x(3)^5, x(1)*x(3)^3+x(4)^6;
list Lmb=1,list(0,0,0,0),list(0,0,0,0),list(0,0,0,0),iniD(4),iniD(4),list(0,0,0,0),-
list L=data(J,2,4);
list LL=determinecenter(L[1],L[2],2,4,0,0,Lmb,flag,0,-1); // Compute the first center

D.5.12.4 Blowupcenter

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `Blowupcenter(center,id,nchart,infochart,c,n,cstep);`
 center, infochart lists, id, nchart, n, cstep integers, c number

Compute: The blowing up at the chart IDCHART along the given center

Return: new affine charts and related information, see example

Example:

```
LIB "resbinomial.lib";
ring r = 0,(x(1),y(2),x(3),y(4),x(5..7)),dp;
list flag=identifyvar();
ideal J=x(1)^3-x(3)^2*y(4)^2,x(1)*x(7)*y(2)-x(6)^3*x(5)*y(4)^3,x(5)^3-x(5)^3*y(2)^2;
list Lmb=2,list(0,0,0,0,0,0,0),list(0,0,0,0,0,0,0),list(0,0,0,0,0,0,0),iniD(7),iniD(7);
list L=data(J,3,7);
list L2=determinecenter(L[1],L[2],2,7,0,0,Lmb,flag,0,-1); // Computing the center
module auxpath=[0,-1];
list infochart=0,0,0,L[2],L[1],flag,0,list(0,0,0,0,0,0,0),auxpath,list(),list();
list L3=Blowupcenter(L2[1],1,1,infochart,2,7,0);
L3[1]; // current chart (parent,Y,center,expJ,Coef,flag,Hhist,blwhist,path,hipercoef)

D.5.12.5 Nonhyp

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Compute: The "ideal" generated by the non hyperbolic generators of J

Return: lists with the following information
 newcoef,newJ: coefficients and exponents of the non hyperbolic generators total-
 hyp,totalgen: coefficients and exponents of the hyperbolic generators flaglist: new list
 saying status of variables

Note: the basering `r` is supposed to be a polynomial ring $K[x,y]$, in fact, we work in a localization of $K[x,y]$, of type $K[x,y]_y$ with y invertible variables.

Example:

```

LIB "resbinomial.lib";
ring r = 0,(x(1),y(2),x(3),y(4),x(5..7)),dp;
list flag=identifyvar(); // List giving flag=1 to invertible variables: y(2),y(4)
ideal J=x(1)^3-x(3)^2*y(4)^2,x(1)*x(7)*y(2)-x(6)^3*x(5)*y(4)^3,1-x(5)^2*y(2)^2;
list L=data(J,3,7);
list L2=maxEord(L[1],L[2],3,7,flag);

```

```

L2[1];      // Maximum E-order
⇨ 0
list New=Nonhyp(L[1],L[2],3,7,flag,L2[2]);

D.5.12.6 identifyvar

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `identifyvar();`

Compute: Assign 0 to variables x and 1 to variables y, only necessary at the beginning

Return: list, say l , of size the dimension of the basering
 $l[i]$ is: 0 if the i -th variable is $x(i)$,
 1 if the i -th variable is $y(i)$

Example:

```
LIB "resbinomial.lib";
ring r = 0,(x(1),y(2),x(3),y(4),x(5..7),y(8)),dp;
identifyvar();
⇒ [1]:
⇒ 0

```

D.5.12.7 Edatalist

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: Edatalist(Coef,Exp,k,n,flaglist);
 Coef,Exp,flaglist lists, k,n, integers
 Exp is a list of lists of exponents, k=size(Exp)

Compute: computes a list with the E-order of each term

Return: a list with the E-order of each term

Example:

```
LIB "resbinomial.lib";
ring r = 0,(x(1),y(2),x(3),y(4),x(5..7),y(8)),dp;
list flag=identifyvar();
ideal J=x(1)^3*x(3)-y(2)*y(4)^2,x(5)*y(2)-x(7)*y(4)^2,x(6)^2*(1-y(4)*y(8)^5);
list L=data(J,3,8);

```

D.5.12.8 EOrdlist

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `EOrdlist(Coef,Exp,k,n,flaglist);`
`Coef,Exp,flaglist` lists, `k,n`, integers
`Exp` is a list of lists of exponents, `k=size(Exp)`

Compute: computes de E-order of an ideal given by a list (`Coef,Exp`) and extra information

Return: maximal E-order, and its position=number of generator and term

Example:

```
LIB "resbinomial.lib";
ring r = 0,(x(1),y(2),x(3),y(4),x(5..7),y(8)),dp;
list flag=identifyvar();
ideal J=x(1)^3*x(3)-y(2)*y(4)^2,x(5)*y(2)-x(7)*y(4)^2,x(6)^2*(1-y(4)*y(8)^5),x(7)^4*y(8)^5;
list L=data(J,4,8);
list Eo=EOrdlist(L[1],L[2],4,8,flag);
Eo[1]; // E-order
↦ 0
Eo[2]; // generator giving the E-order
↦ 1
Eo[3]; // term giving the E-order
↦ 2
```

D.5.12.9 maxEord

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `maxEord(Coef,Exp,k,n,flaglist);`
`Coef,Exp,flaglist` lists, `k,n`, integers
`Exp` is a list of lists of exponents, `k=size(Exp)`

Return: computes de maximal E-order of an ideal given by `Coef,Exp`

Example:

```
LIB "resbinomial.lib";
ring r = 0,(x(1),y(2),x(3),y(4),x(5..7),y(8)),dp;
list flag=identifyvar();
ideal J=x(1)^3*x(3)-y(2)*y(4)^2*x(3),x(5)*y(2)-x(7)*y(4)^2,x(6)^2*(1-y(4)*y(8)^5),x(7)^4*y(8)^5;
list L=data(J,4,8);
list M=maxEord(L[1],L[2],4,8,flag);
M[1]; // E-order
↦ 1
```

D.5.12.10 ECoef

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `ECoef(Coef,expP,sP,V,auxc,n,flaglist);`
`Coef, expP, flaglist` lists, `sP, V, n` integers, `auxc` number

Compute: The ideal `E-Coeff_V(P)`, where `V` is a permissible hypersurface which belongs to the center

Return: list of exponents, list of coefficients and classification of the ideal `E-Coeff_V(P)`

Example:

```

LIB "resbinomial.lib";
ring r = 0,(x(1),y(2),x(3),y(4),x(5..7)),dp;
list flag=identifyvar();
ideal P=x(1)^2*x(3)^5-x(5)^7*y(4),x(6)^3*y(2)^5-x(7)^5,x(5)^3*x(6)-y(4)^3*x(1)^5;
list L=data(P,3,7);
list L2=ECoeff(L[1],L[2],3,1,3,7,flag);
L2[1]; // exponents of the E-Coefficient ideal respect to x(1)

D.5.12.11 elimrep

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `elimrep(L)`; `L` is a list

Compute: Eliminate repeated terms from a list

Return: the same list without repeated terms

Example:

```

LIB "resbinomial.lib";
ring r = 0,(x(1..3)),dp;
list L=4,5,2,5,7,8,6,3,2;
elimrep(L);
⇒ [1]:
⇒ 4
⇒ [2]:
⇒ 5
⇒ [3]:
⇒ 2
⇒ [4]:
⇒ 7
⇒ [5]:
⇒ 8
⇒ [6]:
⇒ 6
⇒ [7]:
⇒ 3

```

D.5.12.12 Emaxcont

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: Emaxcont(Coef,Exp,k,n,flag);
 Coef,Exp,flag lists, k,n, integers
 Exp is a list of lists of exponents, k=size(Exp)

Compute: Identify ALL the variables of E-maximal contact

Return: a list with the indexes of the variables of E-maximal contact

Example:

```
LIB "resbinomial.lib";
ring r = 0,(x(1),y(2),x(3),y(4),x(5..7),y(8)),dp;
list flag=identifyvar();
ideal J=x(1)^3*x(3)-y(2)*y(4)^2,x(5)*y(2)-x(7)*y(4)^2,x(6)^2*(1-y(4)*y(8)^5),x(7)^4*y(8)^5;
list L=data(J,4,8);
list hyp=Emaxcont(L[1],L[2],4,8,flag);
hyp[1]; // max E-order=0
↳ 0
hyp[2]; // There are no hypersurfaces of E-maximal contact
↳ empty list
ring r = 0,(x(1),y(2),x(3),y(4),x(5..7),y(8)),dp;
↳ // ** redefining r (ring r = 0,(x(1),y(2),x(3),y(4),x(5..7),y(8)),dp;) ./\
    examples/Emaxcont.sing:9
list flag=identifyvar();
↳ // ** redefining flag (list flag=identifyvar();) ./examples/Emaxcont.sing\
:10
ideal J=x(1)^3*x(3)-y(2)*y(4)^2*x(3),x(5)*y(2)-x(7)*y(4)^2,x(6)^2*(1-y(4)*y(8)^5),x(7)^4*y(8)^5;
list L=data(J,4,8);
list hyp=Emaxcont(L[1],L[2],4,8,flag);
hyp[1]; // the E-order is 1
↳ 1
hyp[2]; // {x(3)=0},{x(5)=0},{x(7)=0} are hypersurfaces of E-maximal contact
↳ [1]:
↳ 3
↳ [2]:
↳ 7
↳ [3]:
↳ 5
```

D.5.12.13 cleanunit

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Compute: We clean (or forget) the units in a monomial, given by "y" variables

Return: The list defining the monomial ideal already cleaned

Example:

```
LIB "resbinomial.lib";
ring r = 0,(x(1),y(2),x(3),y(4)),dp;
list flag=identifyvar();
ideal J=x(1)^3*y(2)*x(3)^5*y(4)^8;
list L=data(J,1,4);
```

```

L[2][1][1]; // list of exponents of the monomial J
⇒ [1]:
⇒ 3
⇒ [2]:
⇒ 1
⇒ [3]:
⇒ 5
⇒ [4]:
⇒ 8
list M=cleanunit(L[2][1][1],4,flag);
M; // new list without units
⇒ [1]:
⇒ 3
⇒ [2]:
⇒ 0
⇒ [3]:
⇒ 5
⇒ [4]:
⇒ 0

```

D.5.12.14 resfunction

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `resfunction(invariant,auxinv,nchart,n);`
invariant, auxinv lists, nchart, n integers

Compute: Patch the resolution function

Return: The complete resolution function

Example:

```

LIB "resbinomial.lib";
ring r = 0,(x(1..2)),dp;
ideal J=x(1)^2-x(2)^3;
list L=Eresol(J);
L[3]; // incomplete resolution function
⇒ [1]:
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 3/2
⇒ [2]:
⇒ @
⇒ [3]:
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 2
⇒ [4]:
⇒ @
⇒ [5]:
⇒ [1]:
⇒ 1
⇒ [2]:

```

```

⇒ 0
⇒ [6]:
⇒ #
⇒ [7]:
⇒ #
resfunction(L[3],L[7],7,2); // complete resolution function
⇒ [1]:
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 3/2
⇒ [2]:
⇒ @
⇒ [3]:
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 2
⇒ [4]:
⇒ @
⇒ [5]:
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ [1]:
⇒ -1
⇒ [2]:
⇒ 1
⇒ [3]:
⇒ 1
⇒ [6]:
⇒ #
⇒ [7]:
⇒ #

```

D.5.12.15 calculateI

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `calculateI(Coef,expJ,c,n,Y,a,b,D);`
 Coef, expJ, D lists, c, b numbers, n,Y integers, a intvec

Return: ideal I, non monomial part of J

Example:

```

LIB "resbinomial.lib";
ring r = 0,(x(1..3)),dp;
list flag=identifyvar();
ideal J=x(1)^4*x(2)^2, x(3)^3;
list Lmb=1,list(0,0,0),list(0,0,0),list(3),iniD(3),iniD(3),list(0,0,0),-1;
list L=data(J,2,3);
list LL=determinecenter(L[1],L[2],3,3,0,0,Lmb,flag,0,-1); // Calculate the center
module auxpath=[0,-1];
list infochart=0,0,0,L[2],L[1],flag,0,list(0,0,0),auxpath,list(),list();

```

```

list L3=Blowupcenter(LL[1],1,1,infochart,3,3,0); // blowing-up and looking to the x(
calculateI(L3[2][1][5],L3[2][1][4],3,3,3,L3[2][1][3],3,iniD(3)); // (I_3)
↳ [1]:
↳ [1]:
↳ 4
↳ [2]:
↳ 2
↳ [3]:
↳ 3
↳ [2]:
↳ [1]:
↳ 0
↳ [2]:
↳ 0
↳ [3]:
↳ 0
// looking to the x(1) chart
calculateI(L3[2][2][5],L3[2][2][4],3,3,1,L3[2][2][3],3,iniD(3)); // (I_3)
↳ [1]:
↳ [1]:
↳ 3
↳ [2]:
↳ 2
↳ [3]:
↳ 0
↳ [2]:
↳ [1]:
↳ [1]:
↳ 0
↳ [2]:
↳ 0
↳ [3]:
↳ 3

```

D.5.12.16 Maxord

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: Maxord(L,n); L list, n integer

Compute: Find the maximal entry of a list, input is a list defining a monomial

Return: maximum entry of a list and its position

Example:

```

LIB "resbinomial.lib";
ring r = 0,(x(1..3)),dp;
ideal J=x(1)^2*x(2)*x(3)^5;
list L=data(J,1,3);
L[2]; // list of exponents
↳ [1]:
↳ [1]:

```

```

↳      [1]:
↳      2
↳      [2]:
↳      1
↳      [3]:
↳      5
Maxord(L[2][1][1],3);
↳ 5 3

```

D.5.12.17 Gamma

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `Gamma(L,c,n)`; L list, c number, n integer

Compute: The Gamma function, resolution function corresponding to the monomial case

Return: lists of maximum exponents in L, value of Gamma function, center of blow up

Example:

```

LIB "resbinomial.lib";
ring r = 0,(x(1..5)),dp;
ideal J=x(1)^2*x(2)*x(3)^5*x(4)^2*x(5)^3;
list L=data(J,1,5);
list G=Gamma(L[2][1][1],9,5); // critical value c=9
G[1]; // maximum exponents in the ideal
↳ [1]:
↳ 5
↳ [2]:
↳ 3
↳ [3]:
↳ 2
G[2]; // maximal value of Gamma function
↳ [1]:
↳ -3
↳ [2]:
↳ 10/9
↳ [3]:
↳ 3,5,4
G[3]; // center given by Gamma
↳ [1]:
↳ 3
↳ [2]:
↳ 5
↳ [3]:
↳ 4

```

D.5.12.18 convertdata

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `convertdata(C,L,n,flaglist)`;
 C, L, flaglist lists, n integer

Compute: Compute the ideal corresponding to the given lists C,L

Return: an ideal whose coefficients are given by C, exponents given by L

Example:

```
LIB "resbinomial.lib";
ring r = 0,(x(1..4),y(5)),dp;
list M=identifyvar();
ideal J=x(1)^2*y(5)^2-x(2)^2*x(3)^2,6*x(4)^2;
list L=data(J,2,5);
L[1]; // Coefficients
↳ [1]:
↳ [1]:
↳ -1
↳ [2]:
↳ 1
↳ [2]:
↳ [1]:
↳ 6
L[2]; // Exponents
↳ [1]:
↳ [1]:
↳ [1]:
↳ 0
↳ [2]:
↳ 2
↳ [3]:
↳ 2
↳ [4]:
↳ 0
↳ [5]:
↳ 0
↳ [2]:
↳ [1]:
↳ 2
↳ [2]:
↳ 0
↳ [3]:
↳ 0
↳ [4]:
↳ 0
↳ [5]:
↳ 2
↳ [2]:
↳ [1]:
↳ [1]:
↳ 0
↳ [2]:
↳ 0
↳ [3]:
↳ 0
↳ [4]:
↳ 2
↳ [5]:
↳ 0
```

```

ideal J2=convertdata(L[1],L[2],5,M);
J2;
↪ J2[1]=-x(2)^2*x(3)^2+x(1)^2*y(5)^2
↪ J2[2]=6*x(4)^2

```

D.5.12.19 lcmofall

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\], page 1480](#)).

Usage: `lcmofall(nchart,mobile);`
 `nchart` integer, `mobile` list of lists

Compute: Compute the lcm of the denominators of the E-orders of all the charts

Return: an integer given the lcm

Note: CALL BEFORE `salida`

Example:

```

LIB "resbinomial.lib";
ring r = 0,(x(1..2)),dp;
ideal J=x(1)^3-x(1)*x(2)^3;
list L=Eresol(J);
L[4]; // 8 charts, rational exponents
↪ 8
L[8][2][2]; // E-orders at the first chart
↪ [1]:
↪ 3
↪ [2]:
↪ 9/2
lcmofall(8,L[8]);
↪ 2

```

D.5.12.20 computemcm

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\], page 1480](#)).

Usage: `computemcm(Eolist);` `Eolist` list

Return: an integer, the least common multiple of the denominators of the E-orders

Note: Make the same as `lcmofall` but for one chart. NECESSARY BECAUSE THE E-ORDERS ARE OF TYPE NUMBER!!

Example:

```

LIB "resbinomial.lib";
ring r = 0,(x(1..2)),dp;
ideal J=x(1)^3-x(1)*x(2)^3;
list L=Eresol(J); // 8 charts, rational exponents
L[8][2][2]; // maximal E-order at the first chart
↪ [1]:
↪ 3
↪ [2]:
↪ 9/2
computemcm(L[8][2][2]);
↪ 2

```

D.5.12.21 constructH

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `constructH(Hhist,n,flag);`
 Hhist intvec, n integer, flag list

Return: the list of exceptional divisors accumulated at this chart

Example:

```
LIB "resbinomial.lib";
ring r = 0,(x(1..3)),dp;
list flag=identifyvar();
ideal J=x(1)^4*x(2)^2, x(1)^2+x(3)^3;
list L=Eresol(J); // 7 charts
// history of the exceptional divisors at the 7-th chart
L[1][7][7]; // blow ups at x(3)-th, x(1)-th and x(1)-th charts
⇒ 0,3,1,1
constructH(L[1][7][7],3,flag);
⇒ [1]:
⇒    _[1]=x(3)
⇒ [2]:
⇒    _[1]=1
⇒ [3]:
⇒    _[1]=x(1)
```

D.5.12.22 constructblwup

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `constructblwup(blwhist,n,chy,flag);`
 blwhist, flag lists, n integer, chy ideal

Return: the ideal defining the map $K[W] \rightarrow K[W_i]$,
 which gives the composition map of all the blowing up leading to this chart

Note: NECESSARY START WITH COLUMNS

Example:

```
LIB "resbinomial.lib";
ring r = 0,(x(1..3)),dp;
list flag=identifyvar();
ideal chy=maxideal(1);
ideal J=x(1)^4*x(2)^2, x(1)^2+x(3)^3;
list L=Eresol(J); // 7 charts
// history of the blow ups at the 7-th chart, center {x(1)=x(3)=0} every time
L[1][7][8]; // blow ups at x(3)-th, x(1)-th and x(1)-th charts
⇒ [1]:
⇒    0,3,0,0
⇒ [2]:

⇒ [3]:
⇒    0,0,1,1
constructblwup(L[1][7][8],3,chy,flag);
⇒ _[1]=x(1)^3*x(3)
⇒ _[2]=x(2)
⇒ _[3]=x(1)^2*x(3)
```

D.5.12.23 constructlastblwup

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `constructlastblwup(blwhist,n,chy,flag);`
 `blwhist`, `flag` lists, `n` integer, `chy` ideal

Return: the ideal defining the last blow up

Note: NECESSARY START WITH COLUMNS

Example:

```
LIB "resbinomial.lib";
ring r = 0,(x(1..3)),dp;
list flag=identifyvar();
ideal chy=maxideal(1);
ideal J=x(1)^4*x(2)^2, x(1)^2+x(3)^3;
list L=Eresol(J); // 7 charts
// history of the blow ups at the 7-th chart, center {x(1)=x(3)=0} every time
L[1][7][8]; // blow ups at x(3)-th, x(1)-th and x(1)-th charts
⇒ [1]:
⇒ 0,3,0,0
⇒ [2]:
⇒ 0,0,0,0
⇒ [3]:
⇒ 0,0,1,1
constructlastblwup(L[1][7][8],3,chy,flag);
⇒ _[1]=x(1)
⇒ _[2]=x(2)
⇒ _[3]=x(1)*x(3)
```

D.5.12.24 genoutput

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `genoutput(chart,mobile,nchart,nsons,n,q,p);`
 `chart`, `mobile`, `nsons` lists, `nchart`, `n`,`q`, `p` integers

Return: two lists, the first one gives the rings corresponding to the final charts, the second one is the list of all rings corresponding to the affine charts of the resolution process

Example:

```
LIB "resbinomial.lib";
ring r = 0,(x(1..2)),dp;
ideal J=x(1)^3-x(1)*x(2)^3;
list L=Eresol(J); // 8 charts, rational exponents
list B=genoutput(L[1],L[8],L[4],L[6],2,2,0); // generates the output
presentTree(B);

D.5.12.25 salida

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `salida(idchart,chart,mobile,numson,previous,a,n,q,p);`
`idchart, numson, n, q, p` integers, `chart, mobile`, lists, `previous` intvec

Compute: CONVERT THE OUTPUT OF A CHART IN A RING, WHERE DEFINE A BASIC OBJECT (BO)

Return: the ring corresponding to the chart

Example:

```

LIB "resbinomial.lib";
ring r = 0,(x(1..2)),dp;
ideal J=x(1)^2-x(2)^3;
list L=Eresol(J);
list B=salida(5,L[1][5],L[8][6],2,L[1][3][3],2,1,0); // chart 5

```

D.5.12.26 iniD

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `iniD(n)`; n integer

Return: list of lists of zeros of size n

Example:

```

LIB "resbinomial.lib";
iniD(3);
↳ [1]:
↳   [1]:
↳     0
↳   [2]:
↳     0
↳   [3]:
↳     0
↳ [2]:
↳   [1]:
↳     0

```

```

⇒      [2]:
⇒      0
⇒      [3]:
⇒      0
⇒ [3]:
⇒      [1]:
⇒      0
⇒      [2]:
⇒      0
⇒      [3]:
⇒      0

```

D.5.12.27 sumlist

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `sumlist(L1,L2)`; L1,L2 lists, (size(L1)==size(L2))

Return: a list, sum of L1 and L2

Example:

```

LIB "resbinomial.lib";
list L1=1,2,3;
list L2=5,9,7;
sumlist(L1,L2);
⇒ [1]:
⇒ 6
⇒ [2]:
⇒ 11
⇒ [3]:
⇒ 10

```

D.5.12.28 reslist

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `reslist(L1,L2)`; L1,L2 lists, (size(L1)==size(L2))

Return: a list, subtraction of L1 and L2

Example:

```

LIB "resbinomial.lib";
list L1=1,2,3;
list L2=5,9,7;
reslist(L1,L2);
⇒ [1]:
⇒ -4
⇒ [2]:
⇒ -7
⇒ [3]:
⇒ -4

```

D.5.12.29 multiplylist

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `multiplylist(L,a)`; L list, a number

Return: list of elements of type number, multiplication of L times a

Example:

```
LIB "resbinomial.lib";
ring r = 0,(x(1..3)),dp;
list L=1,2,3;
multiplylist(L,1/5);
⇒ [1]:
⇒ 1/5
⇒ [2]:
⇒ 2/5
⇒ [3]:
⇒ 3/5
```

D.5.12.30 dividelist

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `dividelist(L1,L2)`; L1,L2 lists

Return: list of elements of type number, division of L1 by L2

Example:

```
LIB "resbinomial.lib";
ring r = 0,(x(1..3)),dp;
list L1=1,2,3;
list L2=5,9,7;
dividelist(L1,L2);
⇒ [1]:
⇒ 1/5
⇒ [2]:
⇒ 2/9
⇒ [3]:
⇒ 3/7
```

D.5.12.31 createlist

Procedure from library `resbinomial.lib` (see [Section D.5.12 \[resbinomial.lib\]](#), page 1480).

Usage: `createlist(L1,L2)`; L1,L2 lists, (`size(L1)==size(L2)`)

Return: list of lists of two elements, the first one of L1 and the second of L2

Example:

```
LIB "resbinomial.lib";
list L1=1,2,3;
list L2=5,9,7;
createlist(L1,L2);
⇒ [1]:
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 5
⇒ [2]:
```

```

⇒      [1]:
⇒      2
⇒      [2]:
⇒      9
⇒ [3]:
⇒      [1]:
⇒      3
⇒      [2]:
⇒      7

```

D.5.13 resgraph.lib

Library: resgraph.lib

Purpose: Visualization of Resolution Data

Author: A. Fruehbis-Krueger, anne@mathematik.uni-kl.de,

Note: This library uses the external programs surf, graphviz and imagemagick.
Input data is assumed to originate from resolve.lib and reszeta.lib

Procedures:

D.5.13.1 InterDiv

Procedure from library **resgraph.lib** (see [Section D.5.13 \[resgraph.lib\]](#), page 1528).

Usage: InterDiv(M[,name]);
M = matrix
name = string

Assume: - M is first list entry of output of 'intersectionDiv'
from library reszeta.lib
- write permission in the current directory or in the
directory in which the file with name 'name' resides

Create: file 'name.jpg' containing dual graph of resolution
if filename is given

Note: only available on UNIX-type systems and programs
'display' (imagemagick package) and 'dot' (Graphviz package) need to
be in the standard search PATH

Return: nothing, only generating graphics output in separate window

D.5.13.2 ResTree

Procedure from library **resgraph.lib** (see [Section D.5.13 \[resgraph.lib\]](#), page 1528).

Usage: ResTree(L,M[,name][,mark]);
L = list
M = matrix
name = string
mark = intvec

Assume: - L is the output of 'resolve' from resolve.lib
- M is first entry of output of 'collectDiv(L);' from reszeta.lib

- write permission in the current directory or in the directory in which the file with name 'name' resides
- mark intvec of size size(L[2])
- mark[i]=0 (default) border of box black
- mark[i]=1 border of box red

Create: file 'name.jpg' containing the tree of charts of L
if filename is given

Note: only available on UNIX-type systems and programs
'display' (imagemagick package) and 'dot' (Graphviz package) need to
be in the standard search PATH

Return: nothing, only generating graphics output in separate window

D.5.13.3 finalCharts

Procedure from library `resgraph.lib` (see [Section D.5.13 \[resgraph.lib\]](#), page 1528).

Usage: finalCharts(L1,L2,iv[,name]);
L1 = list
L2 = list
iv = intvec
name = string

Assume: - L1 is the output of 'resolve' from `resolve.lib`
- L2 is the output of 'intersectionDiv(L1)' from `reszeta.lib`
- iv is the first entry of the output of 'abstractR(L1)'
- write permission in the current directory or in the directory in which the file with name 'name' resides

Create: - new windows in which surf-images of the final charts are presented
- several '.ras' files in the directory in which 'name' resides

Note: only available on UNIX-type systems
external programs 'surf' and 'display' (imagemagick package) need to be
in the standard search PATH

Return: nothing, only generating graphics output in separate window

D.5.14 resjung.lib

Library: resjung.lib

Purpose: Resolution of surface singularities (Desingularization) Algorithm of Jung

Author: Philipp Renner, philipp_renner@web.de

Procedures:

D.5.14.1 jungresolve

Procedure from library `resjung.lib` (see [Section D.5.14 \[resjung.lib\]](#), page 1529).

Usage: jungresolve(ideal J[,is_noeth]);
J = ideal
i = int

Assume: J = two dimensional ideal

Return: a list l of rings
 $l[i]$ is a ring containing two Ideals: $QIdeal$ and $BMap$. $BMap$ defines a birational morphism from $V(QIdeal) \rightarrow V(J)$, such that $V(QIdeal)$ is smooth. For this the algorithm computes first with `jungnormal` a representation of $V(J)$ with Hirzebruch-Jung singularities and then it uses Villamayor's algorithm to resolve these singularities. If `is_noeth=1` the algorithm assumes J is in noether position with respect to the last two variables. As a default or if `is_noeth = 0` the algorithm computes a coordinate change such that J is in noether position. NOTE: since the noether position algorithm is randomized the performance can vary significantly.

Example:

```
LIB "resjung.lib";
//Computing a resolution of singularities of the variety z2-x3-y3
ring r = 0,(x,y,z),dp;
ideal I = z2-x3-y3;
//The ideal is in noether position
list l = jungresolve(I,1);
def R1 = l[1];
def R2 = l[2];
setring R1;
QIdeal;
⇨ QIdeal[1]=T(1)*x(2)^2*y(1)-T(2)*x
⇨ QIdeal[2]=T(2)*x(2)^2*y(1)-x
⇨ QIdeal[3]=x(2)^2*y(1)^2-x(2)^2*y(1)-T(1)*x
⇨ QIdeal[4]=T(1)^2-T(2)*y(1)+T(2)
⇨ QIdeal[5]=T(1)*T(2)-y(1)+1
⇨ QIdeal[6]=T(2)^2-T(1)
⇨ QIdeal[7]=x(2)^6*y(1)^4-x(2)^6*y(1)^3-x^3
BMap;
⇨ BMap[1]=x
⇨ BMap[2]=x(2)^2*y(1)
⇨ BMap[3]=x(2)^3*y(1)^2
setring R2;
QIdeal;
⇨ QIdeal[1]=T(2)*x(1)^2+x
⇨ QIdeal[2]=T(1)*x(1)^2*y(0)-T(2)*x
⇨ QIdeal[3]=x(1)^2*y(0)^2-x(1)^2*y(0)-T(1)*x
⇨ QIdeal[4]=T(1)^2-T(2)*y(0)+T(2)
⇨ QIdeal[5]=T(1)*T(2)+y(0)^2-y(0)
⇨ QIdeal[6]=T(2)^2+T(1)*y(0)
⇨ QIdeal[7]=x(1)^6*y(0)^3-x(1)^6*y(0)^2+x^3
BMap;
⇨ BMap[1]=x
⇨ BMap[2]=x(1)^2*y(0)
⇨ BMap[3]=x(1)^3*y(0)
```

D.5.14.2 jungnormal

Procedure from library `resjung.lib` (see [Section D.5.14 \[resjung.lib\]](#), page 1529).

Usage: jungnormal(ideal J[,is_noeth]);
 J = ideal
 i = int

Assume: J = two dimensional ideal

Return: a list l of rings
 l[i] is a ring containing two Ideals: QIdeal and BMap. BMap defines a birational morphism from $V(\text{QIdeal}) \rightarrow V(J)$, such that $V(\text{QIdeal})$ has only singularities of Hizebuch-Jung type. If is_noeth=1 the algorithm assumes J is in noether position with respect to the last two variables. As a default or if is_noeth = 0 the algorithm computes a coordinate change such that J is in noether position. NOTE: since the noether position algorithm is randomized the performance can vary significantly.

Example:

```
LIB "resjung.lib";
//Computing a resolution of singularities of the variety z2-x3-y3
ring r = 0,(x,y,z),dp;
ideal I = z2-x3-y3;
//The ideal is in noether position
list l = jungnormal(I,1);
def R1 = l[1];
def R2 = l[2];
setring R1;
QIdeal;
⇨ QIdeal[1]=T(1)*x(2)^2*y(1)-T(2)*x
⇨ QIdeal[2]=T(2)*x(2)^2*y(1)-x
⇨ QIdeal[3]=-T(1)*x+x(2)^2*y(1)^2-x(2)^2*y(1)
⇨ QIdeal[4]=T(1)^2-T(2)*y(1)+T(2)
⇨ QIdeal[5]=T(1)*T(2)-y(1)+1
⇨ QIdeal[6]=T(2)^2-T(1)
⇨ QIdeal[7]=x(2)^6*y(1)^4-x(2)^6*y(1)^3-x^3
BMap;
⇨ BMap[1]=x
⇨ BMap[2]=x(2)^2*y(1)
⇨ BMap[3]=x(2)^3*y(1)^2
setring R2;
QIdeal;
⇨ QIdeal[1]=T(2)*x(1)^2+x
⇨ QIdeal[2]=T(1)*x(1)^2*y(0)-T(2)*x
⇨ QIdeal[3]=-T(1)*x+x(1)^2*y(0)^2-x(1)^2*y(0)
⇨ QIdeal[4]=T(1)^2-T(2)*y(0)+T(2)
⇨ QIdeal[5]=T(1)*T(2)+y(0)^2-y(0)
⇨ QIdeal[6]=T(2)^2+T(1)*y(0)
⇨ QIdeal[7]=x(1)^6*y(0)^3-x(1)^6*y(0)^2+x^3
BMap;
⇨ BMap[1]=x
⇨ BMap[2]=x(1)^2*y(0)
⇨ BMap[3]=x(1)^3*y(0)
```

D.5.14.3 jungfib

Procedure from library `resjung.lib` (see [Section D.5.14 \[resjung.lib\]](#), page 1529).

Usage: jungfib(J[,is_noeth]);
 J = ideal
 j = int

Assume: J = two dimensional ideal

Return: a list l of rings
 l[i] is a ring containing two Ideals: QIdeal and BMap. BMap defines a birational morphism from $V(\text{QIdeal}) \rightarrow V(J)$, such that $V(\text{QIdeal})$ has only quasi-ordinary singularities.
 If is_noeth=1 the algorithm assumes J is in noether position with respect to the last two variables. As a default or if is_noeth = 0 the algorithm computes a coordinate change such that J is in noether position. NOTE: since the noether position algorithm is randomized the performance can vary significantly.

Example:

```
LIB "resjung.lib";
//Computing a resolution of singularities of the variety z2-x3-y3
ring r = 0,(x,y,z),dp;
ideal I = z2-x3-y3;
//The ideal is in noether position
list l = jungfib(I,1);
def R1 = l[1];
def R2 = l[2];
setring R1;
QIdeal;
↪ QIdeal[1]=x(2)^6*y(1)^4-x(2)^6*y(1)^3-x^3
BMap;
↪ BMap[1]=x
↪ BMap[2]=x(2)^2*y(1)
↪ BMap[3]=x(2)^3*y(1)^2
setring R2;
QIdeal;
↪ QIdeal[1]=x(1)^6*y(0)^3-x(1)^6*y(0)^2+x^3
BMap;
↪ BMap[1]=x
↪ BMap[2]=x(1)^2*y(0)
↪ BMap[3]=x(1)^3*y(0)
```

D.5.15 resolve_lib

Library: resolve.lib

Purpose: Resolution of singularities (Desingularization) Algorithm of Villamayor

Authors: A. Fruehbis-Krueger, anne@mathematik.uni-kl.de,
 G. Pfister, pfister@mathematik.uni-kl.de

References:

- [1] J.Kollar: Lectures on Resolution of Singularities, Princeton University Press (2007) (contains large overview over various known methods for curves and surfaces as well as a detailed description of the approach in the general case)
- [2] A.Bravo, S.Encinas, O.Villamayor: A Simplified Proof of Desingularisation and Applications, Rev. Math. Iberoamericana 21 (2005), 349-458
 (description of the algorithmic proof of desingularization in characteristic zero which

underlies this implementation)

[3] A.Fruehbs-Krueger: Computational Aspects of Singularities, in J.-P. Brasselet, J.Damon et al.: Singularities in Geometry and Topology, World Scientific Publishing, 253–327 (2007)

(chapter 4 contains a detailed discussion on algorithmic desingularization and efficiency aspects thereof)

Procedures:

D.5.15.1 blowUp

Procedure from library `resolve.lib` (see [Section D.5.15 \[resolve.lib\]](#), page 1532).

Usage: `blowUp(J,C[W][,E]);`
 W, J, C = ideals,
 E = list

Assume: J = ideal containing W ($W = 0$ if not specified)
 C = ideal containing J
 E = list of smooth hypersurfaces (e.g. exceptional divisors)

Note: W the ideal of the ambient space, C the ideal of the center of the blowup and J the ideal of the variety
 Important difference to `blowUp2`:
 - the ambient space $V(W)$ is blown up and $V(J)$ transformed in it
 - $V(C)$ is assumed to be non-singular

Compute: the blowing up of W in C , the exceptional locus, the strict transform of J and the blowup map

Return: list, say l , of size at most $\text{size}(C)$,
 $l[i]$ is the affine ring corresponding to the i -th chart each $l[i]$ contains the ideals
 - aS , ideal of the blownup ambient space
 - sT , ideal of the strict transform
 - eD , ideal of the exceptional divisor
 - bM , ideal corresponding to the blowup map
 $l[i]$ also contains a list BO , which can best be viewed with `showBO(BO)` detailed information on the data type BO can be viewed via the command `showDataTypes()`;

Example:

```
LIB "resolve.lib";
ring R=0,(x,y),dp;
ideal J=x^2-y^3;
ideal C=x,y;
list blow=blowUp(J,C);
def Q=blow[1];
setring Q;

⇨ aS[1]=0
sT;
⇨ sT[1]=y(1)^2-x(2)
eD;
⇨ eD[1]=x(2)
bM;
⇨ bM[1]=x(2)*y(1)
⇨ bM[2]=x(2)
```

D.5.15.2 blowUp2

Procedure from library `resolve.lib` (see [Section D.5.15 \[resolve.lib\]](#), page 1532).

Usage: `blowUp2(J,C);`
 `J,C = ideals,`

Assume: `C = ideal` containing `J`

Note: `C` the ideal of the center of the blowup and `J` the ideal of the variety
 Important differences to `blowUp`:
 - $V(J)$ itself is blown up, not the ambient space
 - `C` is not assumed to be non-singular

Compute: the blowing up of `J` in `C`, the exceptional locus and the blow-up map

Return: list, say `l`, of size at most `size(C)`,
 `l[i]` is the affine ring corresponding to the i -th chart each `l[i]` contains the ideals
 - `Jnew`, ideal of the blowup `J`
 - `eD`, ideal of the new exceptional divisor
 - `bM`, ideal corresponding to the blowup map

Example:

```
LIB "resolve.lib";
ring r=0,(x,y,z),dp;
ideal I=z2-x^3*y^2;
ideal C=z,xy;
list li=blowUp2(I,C);
size(li);                // number of charts
⇒ 2
def S1=li[1];
setring S1;              // chart 1
basing;
⇒ // coefficients: QQ
⇒ // number of vars : 3
⇒ //      block   1 : ordering dp
⇒ //      : names   x(1) x(3) y(2)
⇒ //      block   2 : ordering C
Jnew;
⇒ Jnew[1]=x(1)*y(2)^2-1
eD;
⇒ eD[1]=x(3)
⇒ eD[2]=x(1)*y(2)^2-1
bM;
⇒ bM[1]=x(1)
⇒ bM[2]=x(3)*y(2)^3
⇒ bM[3]=x(3)
def S2=li[2];
setring S2;              // chart 2
basing;
⇒ // coefficients: QQ
⇒ // number of vars : 2
⇒ //      block   1 : ordering dp
⇒ //      : names   x(2) y(1)
⇒ //      block   2 : ordering C
```

```

Jnew;
↪ Jnew[1]=0
eD;
↪ eD[1]=x(2)*y(1)^2
bM;
↪ bM[1]=y(1)^2
↪ bM[2]=x(2)
↪ bM[3]=x(2)*y(1)^3

```

D.5.15.3 Center

Procedure from library `resolve.lib` (see [Section D.5.15 \[resolve.lib\]](#), page 1532).

Usage: `Center(J,W)[,E]`
 J, W = ideals
 E = list

Assume: J = ideal containing W ($W = 0$ if not specified)
 E = list of smooth hypersurfaces (e.g. exceptional divisors)

Compute: the center of the blow-up of J for the resolution algorithm of [Bravo,Encinas,Villamayor]

Return: ideal, describing the center

Example:

```

LIB "resolve.lib";
ring R=0,(x,y),dp;
ideal J=x2-y3;
Center(J);
↪ _[1]=y
↪ _[2]=x

```

D.5.15.4 resolve

Procedure from library `resolve.lib` (see [Section D.5.15 \[resolve.lib\]](#), page 1532).

Usage: `resolve (J);` or `resolve (J,i,k);`
 J ideal
 i, k int

Compute: a resolution of J ,
 if $i > 0$ debugging is turned on according to the following switches:
 j1: value 0 or 1; turn off or on correctness checks in all steps
 j2: value 0 or 2; turn off or on debugCenter
 j3: value 0 or 4; turn off or on debugBlowUp
 j4: value 0 or 8; turn off or on debugCoeff
 j5: value 0 or 16; turn off or on debugging of Intersection with E^\sim -
 j6: value 0 or 32; turn off or on stop after pass through the loop
 $i = j1 + j2 + j3 + j4 + j5 + j6$

Return: a list l of 2 lists of rings
 $l[1][i]$ is a ring containing a basic object BO , the result of the resolution.
 $l[2]$ contains all rings which occurred during the resolution process

Note: result may be viewed in a human readable form using `presentTree()`

Example:

```

LIB "resolve.lib";
ring R=0,(x,y,z),dp;
ideal J=x3+y5+yz2+xy4;
list L=resolve(J,0);
def Q=L[1][7];
setring Q;
showBO(B0);
↳
↳ ==== Ambient Space:
↳ _[1]=0
↳
↳ ==== Ideal of Variety:
↳ _[1]=x(1)^4*x(3)^2*y(1)+x(1)^2+y(1)+1
↳
↳ ==== Exceptional Divisors:
↳ [1]:
↳   _[1]=1
↳ [2]:
↳   _[1]=y(1)
↳ [3]:
↳   _[1]=1
↳ [4]:
↳   _[1]=x(1)
↳ [5]:
↳   _[1]=x(3)
↳
↳ ==== Images of variables of original ring:
↳ _[1]=x(1)^6*x(3)^5*y(1)^2
↳ _[2]=x(1)^4*x(3)^3*y(1)
↳ _[3]=x(1)^7*x(3)^6*y(1)^2
↳

```

D.5.15.5 showBO

Procedure from library `resolve.lib` (see [Section D.5.15 \[resolve.lib\]](#), page 1532).

Usage: `showBO(BO);`
 BO=basic object, a list: ideal W,
 ideal J,
 intvec b (already truncated for Coeff),
 list Ex (already truncated for Coeff),
 ideal ab,
 intvec v,
 intvec w (already truncated for Coeff),
 matrix M

Return: nothing, only pretty printing

D.5.15.6 presentTree

Procedure from library `resolve.lib` (see [Section D.5.15 \[resolve.lib\]](#), page 1532).

Usage: `presentTree(L);`
 L=list, output of resolve

Return: nothing, only pretty printing of the output data of `resolve()`

D.5.15.7 showDataTypes

Procedure from library `resolve.lib` (see [Section D.5.15 \[resolve.lib\]](#), page 1532).

Usage: `showDataTypes();`

Return: nothing, only pretty printing of extended version of help text

D.5.15.8 blowUpBO

Procedure from library `resolve.lib` (see [Section D.5.15 \[resolve.lib\]](#), page 1532).

Usage: `blowUpBO (BO,C,e);`
`BO` = basic object, a list: ideal `W`,
ideal `J`,
intvec `b`,
list `Ex`,
ideal `ab`,
intvec `v`,
intvec `w`,
matrix `M`
`C` = ideal
`e` = integer (0 usual blowing up, 1 deleting extra charts, 2 deleting no charts)

Assume: `R` = basering, a polynomial ring, `W` an ideal of `R`,
`J` = ideal containing `W`,
`C` = ideal containing `J`

Compute: the blowing up of `BO[1]` in `C`, the exceptional locus, the strict transform of `BO[2]`

Note: `blowUpBO` may be applied to basic objects in the sense of [Bravo, Encinas, Villamayor] in the following referred to as `BO` and to presentations in the sense of [Bierstone, Milman] in the following referred to as `BM`.

Return: a list `l` of length at most `size(C)`,
`l[i]` is a ring containing an object `BO` resp. `BM`:
`BO[1]=BM[1]` an ideal, say `Wi`, defining the ambient space of the *i*-th chart of the blowing up
`BO[2]=BM[2]` an ideal defining the strict transform
`BO[3]` intvec, the first integer `b` such that in the original object $(\Delta^b(\text{BO}[2]))=1$
the subsequent integers have the same property for Coeff-Objects of `BO[2]` used when determining the center
`BM[3]` intvec, `BM[3][i]` is the assigned multiplicity of `BM[2][i]`
`BO[4]=BM[4]` the list of exceptional divisors
`BO[5]=BM[5]` an ideal defining the map $K[W] \longrightarrow K[Wi]$
`BO[6]=BM[6]` an intvec `BO[6][j]=1` indicates that $\langle \text{BO}[4][j], \text{BO}[2] \rangle = 1$, i.e. the strict transform does not meet the *j*-th exceptional divisor
`BO[7]` intvec, the index of the first blown-up object in the resolution process leading to this object for which the value of `b` was `BO[3]` the subsequent ones are the indices for the Coeff-Objects of `BO[2]` used when determining the center
`BM[7]` intvec, `BM[7][i]` is the index at which the $(2i-1)$ st entry of the invariant first

reached its current maximal value
 $BO[8]=BM[8]$ a matrix indicating that $BO[4][i]$ meets $BO[4][j]$ by $BO[8][i,j]=1$ for $i < j$
 $BO[9]$ empty
 $BM[9]$ the invariant

Example:

```
LIB "resolve.lib";
ring R=0,(x,y),dp;
ideal W;
ideal J=x2-y3;
intvec b=1;
list E;
ideal abb=maxideal(1);
intvec v;
intvec w=-1;
matrix M;
intvec ma;
list B0=W,J,b,E,abb,v,w,M,ma;
ideal C=CenterB0(B0)[1];
list blow=blowUpB0(B0,C,0);
def Q=blow[1];
setring Q;
B0;
⇒ [1]:
⇒   _[1]=0
⇒ [2]:
⇒   _[1]=y(1)^2-x(2)
⇒ [3]:
⇒   1
⇒ [4]:
⇒   [1]:
⇒   _[1]=x(2)
⇒ [5]:
⇒   _[1]=x(2)*y(1)
⇒   _[2]=x(2)
⇒ [6]:
⇒   0
⇒ [7]:
⇒   -1
⇒ [8]:
⇒   _[1,1]=0
⇒ [9]:
⇒   0
```

D.5.15.9 createBO

Procedure from library `resolve.lib` (see [Section D.5.15 \[resolve.lib\]](#), page 1532).

Usage: `createBO(J[W][E]);`
 J, W = ideals
 E = list

Assume: J = ideal containing W ($W = 0$ if not specified)
 E = list of smooth hypersurfaces (e.g. exceptional divisors)

Return: list BO representing a basic object :
 BO[1] ideal W, if W has been specified; ideal(0) otherwise BO[2] ideal J
 BO[3] intvec
 BO[4] the list E of exceptional divisors if specified; empty list otherwise
 BO[5] an ideal defining the identity map
 BO[6] an intvec
 BO[7] intvec
 BO[8] a matrix
 entries 3,5,6,7,8 are initialized appropriately for use of CenterBO and blowUpBO

Example:

```
LIB "resolve.lib";
ring R=0,(x,y,z),dp;
ideal J=x2-y3;
createBO(J,ideal(z));
⇒ [1]:
⇒ _[1]=z
⇒ [2]:
⇒ _[1]=-y3+x2
⇒ [3]:
⇒ 0
⇒ [4]:
⇒ empty list
⇒ [5]:
⇒ _[1]=x
⇒ _[2]=y
⇒ _[3]=z
⇒ [6]:
⇒ 0
⇒ [7]:
⇒ -1
⇒ [8]:
⇒ _[1,1]=0
```

D.5.15.10 CenterBO

Procedure from library `resolve.lib` (see [Section D.5.15 \[resolve.lib\]](#), page 1532).

Usage: CenterBO(BO);
 BO = basic object, a list: ideal W,
 ideal J,
 intvec b,
 list Ex,
 ideal ab,
 intvec v,
 intvec w,
 matrix M

Assume: R = basering, a polynomial ring, W an ideal of R,
 J = ideal containing W

Compute: the center of the next blow-up of BO in the resolution algorithm of [Bravo,Encinas,Villamayor]

Return: list l,
 l[1]: ideal describing the center
 l[2]: intvec w obtained in the process of determining l[1]
 l[3]: intvec b obtained in the process of determining l[1]
 l[4]: intvec inv obtained in the process of determining l[1]

Example:

```
LIB "resolve.lib";
ring R=0,(x,y),dp;
ideal W;
ideal J=x2-y3;
intvec b=1;
list E;
ideal abb=maxideal(1);
intvec v;
intvec w=-1;
matrix M;
list BO=W,J,b,E,abb,v,w,M,v;
CenterBO(BO);
⇒ [1]:
⇒   _[1]=y
⇒   _[2]=x
⇒ [2]:
⇒   -1
⇒ [3]:
⇒   2
⇒ [4]:
⇒   0
```

D.5.15.11 Delta

Procedure from library `resolve.lib` (see [Section D.5.15 \[resolve.lib\]](#), page 1532).

Usage: Delta (BO);
 BO = basic object, a list: ideal W,
 ideal J,
 intvec b,
 list Ex,
 ideal ab,
 intvec v,
 intvec w,
 matrix M

Assume: R = basering, a polynomial ring, W an ideal of R,
 J = ideal containing W

Compute: Delta-operator applied to J in the notation of
 [Bravo,Encinas,Villamayor]

Return: ideal

Example:

```
LIB "resolve.lib";
ring R=0,(x,y,z),dp;
ideal W=z^2-x;
```

```

ideal J=x*y^2+x^3;
intvec b=1;
list E;
ideal abb=maxideal(1);
intvec v;
intvec w=-1;
matrix M;
list B0=W,J,b,E,abb,v,w,M;
Delta(B0);
↪ _[1]=z2-x
↪ _[2]=xy
↪ _[3]=3x2z+y2z
↪ _[4]=x3

```

D.5.15.12 DeltaList

Procedure from library `resolve.lib` (see [Section D.5.15 \[resolve.lib\]](#), page 1532).

Usage: DeltaList (BO);
 BO = basic object, a list: ideal W,
 ideal J,
 intvec b,
 list Ex,
 ideal ab,
 intvec v,
 intvec w,
 matrix M

Assume: R = basering, a polynomial ring, W an ideal of R,
 J = ideal containing W

Compute: Delta-operator iteratively applied to J in the notation of [Bravo,Encinas,Villamayor]

Return: list l of length $((\max w\text{-ord}) * b)$,
 $l[i+1]=\Delta^i(J)$

Example:

```

LIB "resolve.lib";
ring R=0,(x,y,z),dp;
ideal W=z^2-x;
ideal J=x*y^2+x^3;
intvec b=1;
list E;
ideal abb=maxideal(1);
intvec v;
intvec w=-1;
matrix M;
list B0=W,J,b,E,abb,v,w,M;
DeltaList(B0);
↪ [1]:
↪   _[1]=x3+xy2
↪ [2]:
↪   _[1]=z2-x
↪   _[2]=xy
↪   _[3]=3x2z+y2z

```

```

↳   _[4]=x3
↳ [3]:
↳   _[1]=x
↳   _[2]=z2
↳   _[3]=yz
↳   _[4]=y2
↳ [4]:
↳   _[1]=z
↳   _[2]=y
↳   _[3]=x

```

D.5.16 reszeta.lib

Library: reszeta.lib

Purpose: topological Zeta-function and some other applications of desingularization

Authors: A. Fruehbis-Krueger, anne@mathematik.uni-kl.de,
G. Pfister, pfister@mathematik.uni-kl.de

References:

[1] Fruehbis-Krueger,A., Pfister,G.: Some Applications of Resolution of Singularities from a Practical Point of View, in Computational Commutative and Non-commutative Algebraic Geometry, NATO Science Series III, Computer and Systems Sciences 196, 104-117 (2005) [2] Fruehbis-Krueger: An Application of Resolution of Singularities: Computing the topological Zeta-function of isolated surface singularities in $(C^3,0)$, in D.Cheniot, N.Dutertre et al.(Editors): Singularity Theory, World Scientific Publishing (2007)

Procedures:

D.5.16.1 intersectionDiv

Procedure from library `reszeta.lib` (see [Section D.5.16 \[reszeta.lib\]](#), page 1542).

Usage: intersectionDiv(L);
L = list of rings

Assume: L is output of resolution of singularities
(only case of isolated surface singularities)

Compute: intersection matrix and genera of the exceptional divisors (considered as curves on the strict transform)

Return: list l, where
l[1]: intersection matrix of exceptional divisors
l[2]: intvec, genera of exceptional divisors
l[3]: divisorList, encoding the identification of the divisors

Example:

```

LIB "reszeta.lib";
ring r = 0,(x(1..3)),dp(3);
ideal J=x(3)^5+x(2)^4+x(1)^3+x(1)*x(2)*x(3);
list re=resolve(J);
list di=intersectionDiv(re);

```

```

di;
⇒ [1]:
⇒   -3,1,1,
⇒   1,-4,1,
⇒   1,1,-2
⇒ [2]:
⇒   0,0,0
⇒ [3]:
⇒   [1]:
⇒       [1]:
⇒           3,1,1
⇒       [2]:
⇒           5,1,1
⇒   [2]:
⇒       [1]:
⇒           3,1,2
⇒       [2]:
⇒           4,1,1
⇒       [3]:
⇒           5,1,2
⇒   [3]:

⇒           4,2,1
⇒       [2]:
⇒           5,2,1
⇒ [4]:
⇒   1,1,1

```

D.5.16.2 spectralNeg

Procedure from library `reszeta.lib` (see [Section D.5.16 \[reszeta.lib\]](#), page 1542).

Usage: spectralNeg(L);
 L = list of rings

Assume: L is output of resolution of singularities

Return: list of numbers, each a spectral number in $(-1,0]$

Example:

```

LIB "reszeta.lib";
ring R=0,(x,y,z),dp;
ideal I=x3+y4+z5;
list L=resolve(I,"K");
spectralNeg(L);
⇒ [1]:
⇒ -13/60
⇒ [2]:
⇒ -1/60
LIB "gmssing.lib";
ring r=0,(x,y,z),ds;
poly f=x3+y4+z5;
spectrum(f);
⇒ [1]:
⇒   _[1]=-13/60

```

D.5.16.3 discrepancy

Usage: discrepancy(L);
 L = list of rings

Return: discrepancies of the given resolution

```
LIB "reszeta.lib";
ring R=0,(x,y,z),dp;
ideal I=x^2+y^2+z^3;
list re=resolve(I);
discrepancy(re);
--> 0,1,1
```

Procedure from library `reszeta.lib` (see [Section D.5.16 \[reszeta.lib\]](#), page 1542).

Compute: local Denef-Loeser zeta function, if string s1 is present and has the value 'local'; global Denef-Loeser zeta function otherwise
if string s1 or s2 has the value "A", additionally the characteristic polynomial of the monodromy is computed

Return: list l
 if a is not present:
 l[1]: string specifying the top. zeta function
 l[2]: string specifying characteristic polynomial of monodromy, if "A" was specified
 if a is present:
 l[1]: string specifying the top. zeta function
 l[2]: list ast,
 ast[1]=chi(Ei^{*})
 ast[2]=chi(Eij^{*})
 ast[3]=chi(Eijk^{*})
 l[3]: intvec nu of multiplicities as needed in computation of zeta function
 l[4]: intvec N of multiplicities as needed in computation of zeta function
 l[5]: string specifying characteristic polynomial of monodromy, if "A" was specified

Example:

```
LIB "reszeta.lib";
ring R=0,(x,y,z),dp;
ideal I=x2+y2+z3;
list re=resolve(I,"K");
zetaDL(re,1);
⇒ [1]:
⇒ (s+4)/(3s2+7s+4)
I=(xz+y2)*(xz+y2+x2)+z5;
list L=resolve(I,"K");
zetaDL(L,1);
⇒ [1]:
⇒ (20s2+130s+87)/(160s3+396s2+323s+87)
//===== expected zeta function =====
// (20s^2+130s+87)/((1+s)*(3+4s)*(29+40s))
//=====
```

D.5.16.5 collectDiv

Procedure from library `reszeta.lib` (see [Section D.5.16 \[reszeta.lib\]](#), page 1542).

Usage: collectDiv(L);
 L = list of rings

Assume: L is output of resolution of singularities

Compute: list representing the identification of the exceptional divisors in the various charts

Return: list l, where
 l[1]: intmat, entry k in position i,j implies BO[4][j] of chart i is divisor k (if k!=0)
 if k==0, no divisor corresponding to i,j
 l[2]: list ll, where each entry of ll is a list of intvecs entry i,j in list ll[k] implies BO[4][j]
 of chart i
 is divisor k
 l[3]: list L

Example:

```
LIB "reszeta.lib";
ring R=0,(x,y,z),dp;
ideal I=xyz+x4+y4+z4;
```

```

//we really need to blow up curves even if the generic point of
//the curve the total transform is n.c.

D.5.16.6 prepEmbDiv

Procedure from library `reszeta.lib` (see [Section D.5.16 \[reszeta.lib\]](#), page 1542).

Usage: `prepEmbDiv(L[,a]);`
 `L` = list of rings
 `a` = integer

Assume: `L` is output of resolution of singularities

Compute: if `a` is not present: exceptional divisors including components of the strict transform
 otherwise: only exceptional divisors

Return: list of \mathbb{Q} -irreducible exceptional divisors (embedded case)

Example:

```

LIB "reszeta.lib";
ring R=0,(x,y,z),dp;
ideal I=x2+y2+z11;
list L=resolve(I);
prepEmbDiv(L);

```

```

D.5.16.7 abstractR

Procedure from library `reszeta.lib` (see [Section D.5.16 \[reszeta.lib\]](#), page 1542).

Usage: `abstractR(L);`
 `L = list of rings`

Assume: `L` is output of resolution of singularities

Note: currently only implemented for isolated surface singularities

Return: list `l`
 `l[1]`: intvec, where
 `l[1][i]=1` if the corresponding ring is a final chart
 of non-embedded resolution
 `l[1][i]=0` otherwise
 `l[2]`: intvec, where
 `l[2][i]=1` if the corresponding ring does not occur
 in the non-embedded resolution
 `l[2][i]=0` otherwise
 `l[3]`: list `L`

Example:

```

LIB "reszeta.lib";
ring r = 0,(x,y,z),dp;
ideal I=x2+y2+z11;
list L=resolve(I);
list absR=abstractR(L);
absR[1];

```

```

⇒ 0,0,1,1,0,1,0,1,0,1,1,0,0,0,0,0,0
absR[2];
⇒ 0,0,0,0,0,0,0,0,0,0,0,1,1,1,1,1,1

```

D.5.16.8 computeV

Procedure from library `reszeta.lib` (see [Section D.5.16 \[reszeta.lib\]](#), page 1542).

Usage: `computeV(L,DL);`
 `L` = list of rings
 `DL` = divisor list

Assume: `L` has structure of output of `resolve`
 `DL` has structure of output of `prepEmbDiv`

Return: `intvec`,
 `i`-th entry is multiplicity of `i`-th divisor in
 pullback of volume form

Example:

```

LIB "reszeta.lib";
ring R=0,(x,y,z),dp;
ideal I=(x-y)*(x-z)*(y-z)-z4;
list re=resolve(I,1);

list iden=prepEmbDiv(re);
intvec v=computeV(re, iden);
v;
⇒ 3,5,8,11,1

```

D.5.16.9 computeN

Procedure from library `reszeta.lib` (see [Section D.5.16 \[reszeta.lib\]](#), page 1542).

Usage: `computeN(L,DL);`
 `L` = list of rings
 `DL` = divisor list

Assume: `L` has structure of output of `resolve`
 `DL` has structure of output of `prepEmbDiv`

Return: `intvec`, `i`-th entry is multiplicity of `i`-th divisor
 in total transform under resolution

Example:

```
LIB "reszeta.lib";
ring R=0,(x,y,z),dp;
ideal I=(x-y)*(x-z)*(y-z)-z4;
list re=resolve(I,1);

D.5.17 schubert.lib

Library: schubert.lib

Purpose: Procedures for Intersection Theory

Author: Hiep Dang, email: hiep@mathematik.uni-kl.de

Overview: We implement new classes (variety, sheaf, stack, graph) and methods for computing with them. An abstract variety is represented by a nonnegative integer which is its dimension and a graded ring which is its Chow ring. An abstract sheaf is represented by a variety and a polynomial which is its Chern character. In particular, we implement the concrete varieties such as projective spaces, Grassmannians, and projective bundles.

An important task of this library is related to the computation of Gromov-Witten invariants. In particular, we implement new tools for the computation in equivariant intersection theory. These tools are based on the localization of moduli spaces of stable maps and Bott's formula. They are useful for the computation of Gromov-Witten invariants. In order to do this, we have to deal with moduli spaces of stable maps, which were introduced by Kontsevich, and the graphs corresponding to the fixed point components of a torus action on the moduli spaces of stable maps.

As an insightful example, the numbers of rational curves on general complete intersection Calabi-Yau threefolds in projective spaces are computed up to degree 6. The results are all in agreement with predictions made from mirror symmetry computations.

Procedures:

D.5.17.1 makeVariety

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), [page 1590](#)).

Usage: `makeVariety(d,i)`; `d` int, `i` ideal

Assume: `d` is a nonnegative integer, `i` is an ideal

Return: variety

Theory: create an abstract variety which has dimension `d`, and its Chow ring should be a quotient ring

Example:

```
LIB "schubert.lib";
ring r = 0,(h,e),wp(1,1);
ideal rels = he,h2+e2;
variety V = makeVariety(2,rels);
V;
⇒ A variety of dimension 2
⇒
V.dimension;
⇒ 2
V.relations;
⇒ _[1]=he
⇒ _[2]=h2+e2
```

D.5.17.2 printVariety

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), [page 1590](#)).

Usage: `printVariety(V)`; `V` variety

Assume: V is an abstract variety

Theory: This is the print function used by Singular to print an abstract variety.

Example:

```
LIB "schubert.lib";
ring r = 0,(h,e),wp(1,1);
ideal rels = he,h2+e2;
variety V = makeVariety(2,rels);
V;
↪ A variety of dimension 2
↪
```

D.5.17.3 productVariety

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `productVariety(U,V)`; U variety, V variety

Input: two abstract varieties

Output: a product variety as an abstract variety

Return: variety

Example:

```
LIB "schubert.lib";
variety P = projectiveSpace(3);
variety G = Grassmannian(2,4);
variety W = productVariety(P,G);
W;
↪ A variety of dimension 7
↪
W.dimension == P.dimension + G.dimension;
↪ 1
def r = W.baseRing;
setring r;
W.relations;
↪ _[1]=h^4
↪ _[2]=q(1)^3-2*q(1)*q(2)
↪ _[3]=q(1)^4-3*q(1)^2*q(2)+q(2)^2
```

See also: [Section D.5.17.5 \[Grassmannian\]](#), page 1593; [Section D.5.17.7 \[projectiveBundle\]](#), page 1594; [Section D.5.17.6 \[projectiveSpace\]](#), page 1594.

D.5.17.4 ChowRing

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `ChowRing(V)`; V variety

Assume: V is an abstract variety

Return: `qring`

Example:

```

LIB "schubert.lib";
ring r = 0,(h,e),wp(1,1);
ideal rels = he,h2+e2;
int d = 2;
variety V = makeVariety(2,rels);
ChowRing(V);
⇒ // coefficients: QQ
⇒ // number of vars : 2
⇒ //          block 1 : ordering dp
⇒ //          : names  h e
⇒ //          block 2 : ordering C
⇒ // quotient ring from ideal ...

```

D.5.17.5 Grassmannian

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: Grassmannian(k,n); k int, n int

Return: variety

Theory: create a Grassmannian $G(k,n)$ as an abstract variety. This abstract variety has dimension $k(n-k)$ and its Chow ring is the quotient ring of a polynomial ring in $n-k$ variables $q(1), \dots, q(n-k)$, which are the Chern classes of tautological quotient bundle on $G(k,n)$, modulo some ideal generated by $n-k$ polynomials which come from the Giambelli formula. The monomial ordering of this Chow ring is 'wp' with vector $(1..k, 1..n-k)$. Moreover, we export the Chern characters of tautological subbundle and quotient bundle on $G(k,n)$ (say 'subBundle' and 'quotientBundle').

Example:

```

LIB "schubert.lib";
variety G24 = Grassmannian(2,4);
G24;
⇒ A variety of dimension 4
⇒
def r = G24.baseRing;
setring r;
subBundle;
⇒ 1/6*q(1)*q(2)-1/2*q(1)^2+q(2)-q(1)+2
quotientBundle;
⇒ -1/6*q(1)*q(2)+1/2*q(1)^2-q(2)+q(1)+2
G24.dimension;
⇒ 4
G24.relations;
⇒ _[1]=q(1)^3-2*q(1)*q(2)
⇒ _[2]=q(1)^4-3*q(1)^2*q(2)+q(2)^2
ChowRing(G24);
⇒ // coefficients: QQ
⇒ // number of vars : 2
⇒ //          block 1 : ordering wp
⇒ //          : names  q(1) q(2)
⇒ //          : weights 1    2
⇒ //          block 2 : ordering C

```

⇒ // quotient ring from ideal ...

See also: [Section D.5.17.7 \[projectiveBundle\]](#), page 1594; [Section D.5.17.6 \[projectiveSpace\]](#), page 1594.

D.5.17.6 projectiveSpace

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `projectiveSpace(n)`; n int

Return: variety

Theory: create a projective space of dimension n as an abstract variety. Its Chow ring is a quotient ring in one variable h modulo the ideal generated by $h^{(n+1)}$.

Example:

```
LIB "schubert.lib";
variety P = projectiveSpace(3);
P;
⇒ A variety of dimension 3
⇒
P.dimension;
⇒ 3
def r = P.baseRing;
setring r;
P.relations;
⇒ _[1]=h4
ChowRing(P);
⇒ // coefficients: QQ
⇒ // number of vars : 1
⇒ //      block   1 : ordering wp
⇒ //                : names     h
⇒ //                : weights   1
⇒ //      block   2 : ordering C
⇒ // quotient ring from ideal ...
```

See also: [Section D.5.17.5 \[Grassmannian\]](#), page 1593; [Section D.5.17.7 \[projectiveBundle\]](#), page 1594.

D.5.17.7 projectiveBundle

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `projectiveBundle(S)`; S sheaf

Input: a sheaf on an abstract variety

Return: variety

Theory: create a projective bundle as an abstract variety. This is related to the enumeration of conics.

Example:

```
LIB "schubert.lib";
variety G = Grassmannian(3,5);
def r = G.baseRing;
setring r;
```

```

sheaf S = makeSheaf(G,subBundle);
sheaf B = dualSheaf(S)^2;
variety PB = projectiveBundle(B);
PB;
↳ A variety of dimension 11
↳
def R = PB.baseRing;
setring R;
QuotientBundle;
↳ 1/1995840*z^5*q(2)^3-1/120960*z^5*q(1)*q(2)^2+1/20160*z^5*q(1)^2*q(2)+1/4\
0320*z^5*q(2)^2-1/10080*z^5*q(1)^3-1/2688*z^5*q(1)*q(2)+1/840*z^5*q(1)^2+\
1/1008*z^5*q(2)-1/180*z^5*q(1)+1/120*z^5-1/36288*z^4*q(2)^3+5/12096*z^4*q\
(1)*q(2)^2-1/448*z^4*q(1)^2*q(2)+5/8064*z^4*q(2)^2+1/252*z^4*q(1)^3+1/100\
8*z^4*q(1)*q(2)-1/72*z^4*q(1)^2+1/144*z^4*q(2)+1/24*z^4+43/72576*z^3*q(2)\
^3-47/8064*z^3*q(1)*q(2)^2+11/504*z^3*q(1)^2*q(2)-1/84*z^3*q(2)^2-1/36*z\
^3*q(1)^3+5/144*z^3*q(1)*q(2)+1/6*z^3-1/192*z^2*q(2)^3+1/36*z^2*q(1)*q(2)\
^2-1/24*z^2*q(1)^2*q(2)+1/36*z^2*q(2)^2+1/2*z^2+1/63*z*q(2)^3-1/36*z*q(1)*\
q(2)^2+z+1
ChowRing(PB);
↳ // coefficients: QQ
↳ // number of vars : 3
↳ //          block   1 : ordering wp
↳ //                      : names      z
↳ //                      : weights    1
↳ //          block   2 : ordering wp
↳ //                      : names      q(1) q(2)
↳ //                      : weights      1    2
↳ //          block   3 : ordering C
↳ // quotient ring from ideal ...

```

See also: [Section D.5.17.5 \[Grassmannian\]](#), page 1593; [Section D.5.17.6 \[projectiveSpace\]](#), page 1594.

D.5.17.8 integral

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `integral(V,f)`; V variety, f poly

Input: a abstract variety and a polynomial

Return: int

Purpose: computing intersection numbers.

Example:

```

LIB "schubert.lib";
variety G = Grassmannian(2,4);
def r = G.baseRing;
setring r;
integral(G,q(1)^4);
↳ 2

```

D.5.17.9 makeSheaf

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `makeSheaf(V,ch);` V variety, ch poly

Return: sheaf

Theory: create a sheaf on an abstract variety, and its Chern character is the polynomial ch.

Example:

```
LIB "schubert.lib";
variety X;
X.dimension = 4;
ring r = 0,(c(1..2),d(1..3)),wp(1..2,1..3);
setring r;
X.baseRing = r;
poly c = 1 + c(1) + c(2);
poly ch = 2 + logg(c,4);
sheaf S = makeSheaf(X,ch);
S;
↳ A sheaf of rank 2
↳
```

See also: [Section D.5.17.10 \[printSheaf\]](#), page 1596; [Section D.5.17.11 \[rankSheaf\]](#), page 1596.

D.5.17.10 printSheaf

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `printSheaf(S);` S sheaf

Return: string

Input: a sheaf

Theory: This is the print function used by Singular to print a sheaf.

Example:

```
LIB "schubert.lib";
variety X;
X.dimension = 4;
ring r = 0,(c(1..2),d(1..3)),wp(1..2,1..3);
setring r;
X.baseRing = r;
poly c = 1 + c(1) + c(2);
poly ch = 2 + logg(c,4);
sheaf S = makeSheaf(X,ch);
S;
↳ A sheaf of rank 2
↳
```

See also: [Section D.5.17.9 \[makeSheaf\]](#), page 1595; [Section D.5.17.11 \[rankSheaf\]](#), page 1596.

D.5.17.11 rankSheaf

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `rankSheaf(S);` S sheaf

Return: int

Input: S is a sheaf

Output: a positive integer which is the rank of a sheaf.

Example:

```
LIB "schubert.lib";
variety G = Grassmannian(2,4);
def R = G.baseRing;
setring R;
sheaf S = makeSheaf(G,subBundle);
rankSheaf(S);
↦ 2
```

See also: [Section D.5.17.9 \[makeSheaf\]](#), page 1595; [Section D.5.17.10 \[printSheaf\]](#), page 1596.

D.5.17.12 totalChernClass

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: totalChernClass(S); S sheaf

Return: poly

Input: S is a sheaf

Output: a polynomial which is the total Chern class of a sheaf

Example:

```
LIB "schubert.lib";
variety X;
X.dimension = 4;
ring r = 0,(c(1..2),d(1..3)),wp(1..2,1..3);
setring r;
X.baseRing = r;
poly c = 1 + c(1) + c(2);
poly ch = 2 + logg(c,4);
sheaf E = makeSheaf(X,ch);
sheaf S = E^3;
totalChernClass(S);
↦ 18*c(1)^2*c(2)+9*c(2)^2+6*c(1)^3+30*c(1)*c(2)+11*c(1)^2+10*c(2)+6*c(1)+1
```

See also: [Section D.5.17.13 \[ChernClass\]](#), page 1597; [Section D.5.17.14 \[topChernClass\]](#), page 1598; [Section D.5.17.15 \[totalSegreClass\]](#), page 1598.

D.5.17.13 ChernClass

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: ChernClass(S,i); S sheaf, i int

Input: S is a sheaf, i is a nonnegative integer

Return: poly

Theory: This is the i-th Chern class of a sheaf

Example:

```
LIB "schubert.lib";
variety X;
X.dimension = 4;
ring r = 0,(c(1..2),d(1..3)),wp(1..2,1..3);
```

```

setring r;
X.baseRing = r;
poly c = 1 + c(1) + c(2);
poly ch = 2 + logg(c,4);
sheaf E = makeSheaf(X,ch);
sheaf S = E^3;
ChernClass(S,1);
 $\mapsto 6*c(1)$ 
ChernClass(S,2);
 $\mapsto 11*c(1)^2+10*c(2)$ 
ChernClass(S,3);
 $\mapsto 6*c(1)^3+30*c(1)*c(2)$ 
ChernClass(S,4);
 $\mapsto 18*c(1)^2*c(2)+9*c(2)^2$ 

```

See also: [Section D.5.17.14 \[topChernClass\]](#), page 1598; [Section D.5.17.12 \[totalChernClass\]](#), page 1597.

D.5.17.14 topChernClass

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `topChernClass(S);` S sheaf

Return: poly

Input: S is a sheaf

Theory: This is the top Chern class of a sheaf

Example:

```

LIB "schubert.lib";
variety G = Grassmannian(2,4);
def R = G.baseRing;
setring R;
sheaf S = makeSheaf(G,quotientBundle);
sheaf B = S^3;
topChernClass(B);
 $\mapsto 27*q(2)^2$ 

```

See also: [Section D.5.17.13 \[ChernClass\]](#), page 1597; [Section D.5.17.12 \[totalChernClass\]](#), page 1597.

D.5.17.15 totalSegreClass

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `totalSegreClass(S);` S sheaf

Return: poly

Input: S is a sheaf

Theory: This is the total Segre class of a sheaf.
SEE ALSO: `totalChernClass`

Example:

```

LIB "schubert.lib";
variety G = Grassmannian(2,4);
def R = G.baseRing;

```

```

setring R;
sheaf S = makeSheaf(G,subBundle);
totalSegreClass(S);
 $\mapsto q(2)+q(1)+1$ 

```

D.5.17.16 dualSheaf

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `dualSheaf(S);` S sheaf

Return: sheaf

Theory: This is the dual of a sheaf

Example:

```

LIB "schubert.lib";
variety G = Grassmannian(2,4);
def R = G.baseRing;
setring R;
sheaf S = makeSheaf(G,subBundle);
sheaf D = dualSheaf(S);
D;
 $\mapsto$  A sheaf of rank 2
 $\mapsto$ 

```

See also: [Section D.5.17.20 \[addSheaf\]](#), page 1601; [Section D.5.17.19 \[quotSheaf\]](#), page 1600; [Section D.5.17.18 \[symmetricPowerSheaf\]](#), page 1600; [Section D.5.17.17 \[tensorSheaf\]](#), page 1599.

D.5.17.17 tensorSheaf

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `tensorSheaf(A,B);` A sheaf, B sheaf

Return: sheaf

Theory: This is the tensor product of two sheaves

Example:

```

LIB "schubert.lib";
variety G = Grassmannian(3,4);
def R = G.baseRing;
setring R;
sheaf S = makeSheaf(G,subBundle);
sheaf Q = makeSheaf(G,quotientBundle);
sheaf T = S*Q;
T;
 $\mapsto$  A sheaf of rank 3
 $\mapsto$ 

```

See also: [Section D.5.17.20 \[addSheaf\]](#), page 1601; [Section D.5.17.16 \[dualSheaf\]](#), page 1599; [Section D.5.17.19 \[quotSheaf\]](#), page 1600; [Section D.5.17.18 \[symmetricPowerSheaf\]](#), page 1600.

D.5.17.18 symmetricPowerSheaf

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `symmetricPowerSheaf(S,n)`; S sheaf, n int

Return: sheaf

Theory: This is the n-th symmetric power of a sheaf

Example:

```
LIB "schubert.lib";
variety G = Grassmannian(2,4);
def R = G.baseRing;
setring R;
sheaf S = makeSheaf(G,quotientBundle);
sheaf B = symmetricPowerSheaf(S,3);
B;
↳ A sheaf of rank 4
↳
sheaf A = S^3;
A;
↳ A sheaf of rank 4
↳
A.ChernCharacter == B.ChernCharacter;
↳ 1
```

See also: [Section D.5.17.20 \[addSheaf\]](#), page 1601; [Section D.5.17.16 \[dualSheaf\]](#), page 1599; [Section D.5.17.19 \[quotSheaf\]](#), page 1600; [Section D.5.17.17 \[tensorSheaf\]](#), page 1599.

D.5.17.19 quotSheaf

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `quotSheaf(A,B)`; A sheaf, B sheaf

Return: sheaf

Theory: This is the quotient of two sheaves

Example:

```
LIB "schubert.lib";
variety G = Grassmannian(3,5);
def r = G.baseRing;
setring r;
sheaf S = makeSheaf(G,subBundle);
sheaf B = dualSheaf(S)^2;
sheaf B3 = dualSheaf(S)^3;
sheaf B5 = dualSheaf(S)^5;
variety PB = projectiveBundle(B);
def R = PB.baseRing;
setring R;
sheaf Q = makeSheaf(PB,QuotientBundle);
sheaf V = dualSheaf(Q)*B3;
sheaf A = B5 - V;
A;
↳ A sheaf of rank 11
```

↪

See also: [Section D.5.17.20 \[addSheaf\]](#), page 1601; [Section D.5.17.16 \[dualSheaf\]](#), page 1599; [Section D.5.17.18 \[symmetricPowerSheaf\]](#), page 1600; [Section D.5.17.17 \[tensorSheaf\]](#), page 1599.

D.5.17.20 addSheaf

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `addSheaf(A,B)`; A sheaf, B sheaf

Return: sheaf

Theory: This is the direct sum of two sheaves.

Example:

```
LIB "schubert.lib";
variety G = Grassmannian(3,5);
def r = G.baseRing;
setring r;
sheaf S = makeSheaf(G,subBundle);
sheaf Q = makeSheaf(G,quotientBundle);
sheaf D = S + Q;
D;
↪ A sheaf of rank 5
↪
D.ChernCharacter == rankSheaf(D);
↪ 1
totalChernClass(D) == 1;
↪ 1
```

See also: [Section D.5.17.16 \[dualSheaf\]](#), page 1599; [Section D.5.17.19 \[quotSheaf\]](#), page 1600; [Section D.5.17.18 \[symmetricPowerSheaf\]](#), page 1600; [Section D.5.17.17 \[tensorSheaf\]](#), page 1599.

D.5.17.21 makeGraphVE

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Assume: `v` is a list of vertices, `e` is a list of edges.

Return: graph with vertices `v` and edges `e`.

Theory: Creates a graph from a list of vertices and edges.

Example:

```
LIB "schubert.lib";
ring r = 0,x,dp;
graph G = makeGraphVE(list(list(0,1,list(0,1,2)),list(1,1,list(1,0,2))),
list(list(0,1,2)));
G;
↪ A graph with 2 vertices and 1 edges
↪
```

D.5.17.22 printGraphG

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `printGraphG(G)`; G graph

Assume: G is a graph.

Theory: This is the print function used by Singular to print a graph.

Example:

```
LIB "schubert.lib";
ring r = 0,x,dp;
graph G = makeGraphVE(list(list(0,1,list(0,1,2)),list(1,1,list(1,0,2))),
list(list(0,1,2)));
G;
↪ A graph with 2 vertices and 1 edges
↪
```

D.5.17.23 moduliSpace

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `moduliSpace(V,d)`; V variety, d int

Assume: V is a projective space and d is a positive integer.

Theory: This is the function used by Singular to create a moduli space of stable maps from a genus zero curve to a projective space.

Example:

```
LIB "schubert.lib";
ring r = 0,(x),dp;
variety P = projectiveSpace(4);
stack M = moduliSpace(P,2);
M;
↪ A moduli space of dimension 11
↪
```

D.5.17.24 printStack

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `printStack(M)`; M stack

Assume: M is a moduli space of stable maps.

Theory: This is the print function used by Singular to print a stack.

Example:

```
LIB "schubert.lib";
ring r = 0,(x),dp;
variety P = projectiveSpace(4);
stack M = moduliSpace(P,2);
M;
↪ A moduli space of dimension 11
↪
```

D.5.17.25 dimStack

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `dimStack(M)`; M stack

Return: int

Input: M is a moduli space of stable maps.

Output: the dimension of moduli space of stable maps.

Example:

```
LIB "schubert.lib";
ring r = 0,(x),dp;
variety P = projectiveSpace(4);
stack M = moduliSpace(P,2);
dimStack(M);
↪ 11
```

D.5.17.26 fixedPoints

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\], page 1590](#)).

Usage: fixedPoints(M); M stack

Return: list

Input: M is a moduli space of stable maps.

Output: a list of graphs corresponding the fixed point components of a torus action on a moduli space of stable maps.

Example:

```
LIB "schubert.lib";
ring r = 0,x,dp;
variety P = projectiveSpace(4);
stack M = moduliSpace(P,2);
def F = fixedPoints(M);
size(F);
↪ 100
typeof(F[1]) == "list";
↪ 1
typeof(F[1][1]) == "graph";
↪ 1
typeof(F[1][2]) == "int";
↪ 1
```

D.5.17.27 contributionBundle

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\], page 1590](#)).

Usage: contributionBundle(M,G,#); M stack, G graph, # list

Return: number

Input: M is a moduli space of stable maps, G is a graph, # is a list.

Output: a number corresponding to the contribution bundle on a moduli space of stable maps at a fixed point component (graph)

Example:

```

LIB "schubert.lib";
ring r = 0,x,dp;
variety P = projectiveSpace(4);
stack M = moduliSpace(P,2);
def F = fixedPoints(M);
graph G = F[1][1];
number f = contributionBundle(M,G);
number g = contributionBundle(M,G,5);
f == g;
↦ 1

```

See also: [Section D.5.17.28 \[normalBundle\]](#), page 1604.

D.5.17.28 normalBundle

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Return: number

Input: M is a moduli space of stable maps, G is a graph

Output: a number corresponding to the normal bundle on a moduli space of stable maps at a graph
hypersurfaces

Example:

```

LIB "schubert.lib";
ring r = 0,x,dp;
variety P = projectiveSpace(4);
stack M = moduliSpace(P,2);
def F = fixedPoints(M);
graph G = F[1][1];
number f = normalBundle(M,G);
f <> 0;
↦ 1

```

See also: [Section D.5.17.27 \[contributionBundle\]](#), page 1603.

D.5.17.29 multipleCover

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: multipleCover(d); d int

Return: number

Theory: This is the contribution of degree d multiple covers of a smooth rational curve as a Gromov-Witten invariant.

Example:

```

LIB "schubert.lib";
ring r = 0,x,dp;
multipleCover(1);
↦ 1
multipleCover(2);
↦ 1/8
multipleCover(3);

```

```

    ↦ 1/27
multipleCover(4);
    ↦ 1/64
multipleCover(5);
    ↦ 1/125
multipleCover(6);
    ↦ 1/216

```

See also: [Section D.5.17.30 \[linesHypersurface\]](#), page 1605; [Section D.5.17.31 \[rationalCurve\]](#), page 1605.

D.5.17.30 linesHypersurface

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `linesHypersurface(n); n int`

Return: number

Theory: This is the number of lines on a general hypersurface of degree $d = 2n-3$ in an n -dimensional projective space.

Example:

```

LIB "schubert.lib";
ring r = 0,x,dp;
linesHypersurface(2);
    ↦ 1
linesHypersurface(3);
    ↦ 27
linesHypersurface(4);
    ↦ 2875
linesHypersurface(5);
    ↦ 698005
linesHypersurface(6);
    ↦ 305093061
linesHypersurface(7);
    ↦ 210480374951
linesHypersurface(8);
    ↦ 210776836330775
linesHypersurface(9);
    ↦ 289139638632755625
linesHypersurface(10);
    ↦ 520764738758073845321

```

See also: [Section D.5.17.30 \[linesHypersurface\]](#), page 1605; [Section D.5.17.29 \[multipleCover\]](#), page 1604.

D.5.17.31 rationalCurve

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `rationalCurve(d,#); d int, # list`

Return: number

Theory: This is the Gromov-Witten invariant corresponding the number of rational curves on a general Calabi-Yau threefold.

Example:

```

LIB "schubert.lib";
ring r = 0,x,dp;
rationalCurve(1);
↦ 2875
/*
rationalCurve(2);
rationalCurve(3);
rationalCurve(4);
rationalCurve(1,list(4,2));
rationalCurve(1,list(3,3));
rationalCurve(1,list(3,2,2));
rationalCurve(1,list(2,2,2,2));
rationalCurve(2,list(4,2));
rationalCurve(2,list(3,3));
rationalCurve(2,list(3,2,2));
rationalCurve(2,list(2,2,2,2));
rationalCurve(3,list(4,2));
rationalCurve(3,list(3,3));
rationalCurve(3,list(3,2,2));
rationalCurve(3,list(2,2,2,2));
rationalCurve(4,list(4,2));
rationalCurve(4,list(3,3));
rationalCurve(4,list(3,2,2));
rationalCurve(4,list(2,2,2,2));
*/

```

See also: [Section D.5.17.30 \[linesHypersurface\]](#), page 1605; [Section D.5.17.29 \[multipleCover\]](#), page 1604.

D.5.17.32 sumofquotients

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `sumofquotient(M,F,#)`; M stack, F list, # list

Return: number

Theory: This is useful for the parallel computation of `rationalCurve`.

Example:

```

LIB "schubert.lib";
ring r = 0,x,dp;
variety P = projectiveSpace(4);
stack M = moduliSpace(P,2);
list F = fixedPoints(M);
sumofquotients(M,F);
↦ 4876875/8
sumofquotients(M,F,list(5));
↦ 4876875/8

```

D.5.17.33 homog_part

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\]](#), page 1590).

Usage: `homog_part(f,n)`; f poly, n int

Return: poly

Purpose: computing the homogeneous component of a polynomial.

Example:

```
LIB "schubert.lib";
ring r = 0, (x,y,z), wp(1,2,3);
poly f = 1+x+x2+x3+x4+y+y2+y3+z+z2+xy+xz+yz+xyz;
homog_part(f,0);
↦ 1
homog_part(f,1);
↦ x
homog_part(f,2);
↦ x2+y
homog_part(f,3);
↦ x3+xy+z
homog_part(f,4);
↦ x4+y2+xz
homog_part(f,5);
↦ yz
homog_part(f,6);
↦ y3+xyz+z2
```

D.5.17.34 homog_parts

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert_lib\], page 1590](#)).

Usage: homog_parts(f,i,j); f poly, i int, j int

Return: poly

Theory: computing a polynomial which is the sum of the homogeneous components of a polynomial.

Example:

```
LIB "schubert.lib";
ring r = 0, (x,y,z), wp(1,2,3);
poly f = 1+x+x2+x3+x4+y+y2+y3+z+z2+xy+xz+yz+xyz;
homog_parts(f,2,4);
↦ x4+y2+xz+x3+xy+z+x2+y
```

D.5.17.35 logg

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert_lib\], page 1590](#)).

Usage: logg(f,n); f poly, n int

Return: poly

Theory: computing Chern characters from total Chern classes.

Example:

```
LIB "schubert.lib";
ring r = 0, (x,y), wp(1,2);
poly f = 1+x+y;
logg(f,4);
↦ 1/24x4-1/6x2y+1/12y2+1/6x3-1/2xy+1/2x2-y+x
```

D.5.17.36 exp

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\], page 1590](#)).

Usage: `exp(f,n);` f poly, n int

Return: poly

Purpose: computing total Chern classes from Chern characters.

Example:

```
LIB "schubert.lib";
ring r = 0,x,dp;
poly f = 3+x;
exp(f,3);
↦ 1/6x3+1/2x2+x+1
```

D.5.17.37 SchubertClass

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\], page 1590](#)).

Usage: `SchubertClass(p);` p list

Input: a list of integers which is a partition

Return: poly

Purpose: compute the Schubert classes on a Grassmannian.

Example:

```
LIB "schubert.lib";
variety G = Grassmannian(2,4);
def r = G.baseRing;
setring r;
list p = 1,1;
SchubertClass(p);
↦ q(1)2-q(2)
```

D.5.17.38 dualPartition

Procedure from library `schubert.lib` (see [Section D.5.17 \[schubert.lib\], page 1590](#)).

Usage: `dualPartition(k,n,p);` k int, n int, p list

Input: two integers and a partition

Return: list

Purpose: compute the dual of a partition.

Example:

```
LIB "schubert.lib";
ring r = 0,(x),dp;
dualPartition(2,4,list(2,1));
↦ [1]:
↦ 1
↦ [2]:
↦ 0
```

See also: [Section D.5.17.37 \[SchubertClass\], page 1608](#).

D.5.18 sheafcoh.lib

Library: sheafcoh.lib

Purpose: Procedures for Computing Sheaf Cohomology

Authors: Wolfram Decker, decker@mathematik.uni-kl.de
 Christoph Lossen, lossen@mathematik.uni-kl.de
 Gerhard Pfister, pfister@mathematik.uni-kl.de
 Oleksandr Motsak, U@D, where $U=\{\text{motsak}\}$, $D=\{\text{mathematik.uni-kl.de}\}$

Procedures:

D.5.18.1 truncate

Procedure from library `sheafcoh.lib` (see [Section D.5.18 \[sheafcoh.lib\]](#), page 1609).

Usage: `truncate(M,d)`; M module, d int

Assume: M is graded, and it comes assigned with an admissible degree vector as an attribute

Return: module

Note: Output is a presentation matrix for the truncation of $\text{coker}(M)$ at degree d .

Example:

```
LIB "sheafcoh.lib";
ring R=0,(x,y,z),dp;
module M=maxideal(3);
homog(M);
↳ 1
// compute presentation matrix for truncated module (R/<x,y,z>^3)_(>=2)
module M2=truncate(M,2);
print(M2);
↳ z,0,0,0,0,0,y, 0, 0,0, 0,0,x, 0, 0, 0, 0, 0,
↳ 0,z,0,0,0,0,-z,y, 0,0, 0,0,0, x, 0, 0, 0, 0,
↳ 0,0,z,0,0,0,0, -z,y,0, 0,0,0, 0, x, 0, 0, 0,
↳ 0,0,0,z,0,0,0, 0, 0,y, 0,0,-z,-y,0, x, 0, 0,
↳ 0,0,0,0,z,0,0, 0, 0,-z,y,0,0, 0, -y,0, x, 0,
↳ 0,0,0,0,0,z,0, 0, 0,0, 0,y,0, 0, 0, -z,-y,x
dimGradedPart(M2,1);
↳ 0
dimGradedPart(M2,2);
↳ 6
// this should coincide with:
dimGradedPart(M,2);
↳ 6
// shift grading by 1:
intvec v=1;
attrib(M,"isHomog",v);
M2=truncate(M,2);
print(M2);
↳ 0, -y,-z,z2,0, 0, yz,0, xz,y2,0, xy,x2,
↳ -z,x, 0, 0, z2,0, 0, yz,0, 0, y2,0, 0,
↳ y, 0, x, 0, 0, z2,0, 0, 0, 0, 0, 0, 0
dimGradedPart(M2,3);
↳ 6
```

D.5.18.2 truncateFast

Procedure from library `sheafcoh.lib` (see [Section D.5.18 \[sheafcoh.lib\]](#), page 1609).

Usage: `truncateFast(M,d)`; M module, d int

Assume: M is graded, and it comes assigned with an admissible degree vector as an attribute 'isHomog'

Return: module

Note: Output is a presentation matrix for the truncation of `coker(M)` at d.
Fast + experimental version. M should be a SB!

Display: If `printlevel` ≥ 1 , step-by step timings will be printed. If `printlevel` ≥ 2 we add progress debug messages if `printlevel` ≥ 3 , even all intermediate results...

Example:

```
LIB "sheafcoh.lib";
ring R=0,(x,y,z,u,v),dp;
module M=maxideal(3);
homog(M);
⇨ 1
// compute presentation matrix for truncated module (R/<x,y,z,u>^3)_(>=2)
int t=timer;
module M2t=truncate(M,2);
t = timer - t;
"// Simple truncate: ", t;
⇨ // Simple truncate: 0
t=timer;
module M2=truncateFast(std(M),2);
t = timer - t;
"// Fast truncate: ", t;
⇨ // Fast truncate: 0
print(M2);
⇨ v,0,0,0,0,0,0,0,0,0,0,0,0,0,0,u, 0, 0, 0, 0, 0,0,0,0,0,0,0,0,0,z, 0, 0,\

D.5.18.3 CM_regularity

Procedure from library `sheafcoh.lib` (see [Section D.5.18 \[sheafcoh.lib\]](#), page 1609).

Usage: CM_regularity(M); M module

Assume: M is graded, and it comes assigned with an admissible degree vector as an attribute

Return: integer, the Castelnuovo-Mumford regularity of `coker(M)`

Note: procedure calls `mres`

Example:

```
LIB "sheafcoh.lib";
ring R=0,(x,y,z,u),dp;
resolution T1=mres(maxideal(1),0);
module M=T1[3];
intvec v=2,2,2,2,2,2;
attrib(M,"isHomog",v);
CM_regularity(M);
↪ 2
```

D.5.18.4 sheafCohBGG

Procedure from library `sheafcoh.lib` (see [Section D.5.18 \[sheafcoh.lib\]](#), page 1609).

Usage: `sheafCohBGG(M,l,h)`; `M` module, `l,h` int

Assume: `M` is graded, and it comes assigned with an admissible degree vector as an attribute, `h>=1`, and the basering has `n+1` variables.

Return: intmat, cohomology of twists of the coherent sheaf `F` on P^n associated to `coker(M)`. The range of twists is determined by `l, h`.

Display: The intmat is displayed in a diagram of the following form: with `displayCohom(A,l,h,nvars(r)-1)`;

	l	l+1	h
n:	$h^n(F(l))$	$h^n(F(l+1))$	$h^n(F(h))$
			
1:	$h^1(F(l))$	$h^1(F(l+1))$	$h^1(F(h))$
0:	$h^0(F(l))$	$h^0(F(l+1))$	$h^0(F(h))$
chi:	$\chi(F(l))$	$\chi(F(l+1))$	$\chi(F(h))$

A '−' in the diagram refers to a zero entry; a '*' refers to a negative entry (= dimension not yet determined). refers to a not computed dimension.

Note: This procedure is based on the Bernstein-Gel'fand-Gel'fand correspondence and on Tate resolution (see [Eisenbud, Floystad, Schreyer: Sheaf cohomology and free resolutions over exterior algebras, Trans AMS 355 (2003)]).
`sheafCohBGG(M,l,h)` does not compute all values in the above table. To determine all values of $h^i(F(d))$, $d=1..h$, use `sheafCohBGG(M,l-n,h+n)`.

Example:

```
LIB "sheafcoh.lib";
// cohomology of structure sheaf on P^4:
//-----
ring r=0,x(1..5),dp;
module M=0;
intmat A=sheafCohBGG(M,-9,4);

D.5.18.5 sheafCohBGGregul

Procedure from library `sheafcoh.lib` (see [Section D.5.18 \[sheafcoh.lib\]](#), page 1609).

Usage: `sheafCohBGGregul(M,l,h)`; M module, l,h int, reg int

Assume: M is graded, and it comes assigned with an admissible degree vector as an attribute, $h \geq 1$, and the basering has $n+1$ variables.

Return: intmat, cohomology of twists of the coherent sheaf F on P^n associated to `coker(M)`. The range of twists is determined by l, h.

Note: This procedure is based on the Bernstein-Gel'fand-Gel'fand correspondence and on Tate resolution (see [Eisenbud, Floystad, Schreyer: Sheaf cohomology and free resolutions over exterior algebras, Trans AMS 355 (2003)]).
`sheafCohBGG(M,l,h)` does not compute all values in the above table. To determine all values of $h^i(F(d))$, $d=1..h$, use `sheafCohBGG(M,l-n,h+n)`.

Example:

```

LIB "sheafcoh.lib";
// cohomology of structure sheaf on P^4:
//-----
ring r=0,x(1..5),dp;
module M=0;
def A=sheafCohBGGregul(M,-9,4,CM_regularity(M));

D.5.18.6 sheafCohBGGregul_w

Procedure from library `sheafcoh.lib` (see [Section D.5.18 \[sheafcoh.lib\]](#), page 1609).

- Usage:** `sheafCohBGGregul_w(M,l,h,w)`; M module, l, h int, reg int, w intvec
- Assume:** M is graded, and it comes assigned with an admissible degree vector w , $h \geq 1$, and the basering has $n+1$ variables.
- Return:** intmat, cohomology of twists of the coherent sheaf F on P^n associated to $coker(M)$. The range of twists is determined by l, h .
- Note:** This procedure is based on the Bernstein-Gel'fand-Gel'fand correspondence and on Tate resolution (see [Eisenbud, Floystad, Schreyer: Sheaf cohomology and free resolutions over exterior algebras, Trans AMS 355 (2003)]).
`sheafCohBGG(M,l,h)` does not compute all values in the above table. To determine all values of $h^i(F(d))$, $d=1..h$, use `sheafCohBGG(M,l-n,h+n)`.

Example:

```

LIB "sheafcoh.lib";
// cohomology of cotangential bundle on P^3:
//-----
ring R=0,(x,y,z,u),dp;
resolution T1=mres(maxideal(1),0);
module M=T1[3];

```

```

intvec v=2,2,2,2,2,2;
def B=sheafCohBGGregul_w(M,-8,4,CM_regularity(M),v);
B;
↳ 189,120,70,36,15,4,0,0,0,0,-1,-1,-1,
↳ -1,0,0,0,0,0,0,0,0,0,-1,-1,
↳ -1,-1,0,0,0,0,0,0,1,0,0,0,-1,
↳ -1,-1,-1,0,0,0,0,0,0,0,6,20,45

```

See also: [Section D.5.18.10 \[dimH\]](#), page 1623; [Section D.5.18.12 \[displayCohom\]](#), page 1624; [Section D.5.18.8 \[sheafCoh\]](#), page 1620.

D.5.18.7 sheafCohBGG2

Procedure from library `sheafcoh.lib` (see [Section D.5.18 \[sheafcoh.lib\]](#), page 1609).

Usage: `sheafCohBGG2(M,l,h)`; M module, l,h int

Assume: M is graded, and it comes assigned with an admissible degree vector as an attribute, $h \geq 1$, and the basering has $n+1$ variables.

Return: intmat, cohomology of twists of the coherent sheaf F on P^n associated to `coker(M)`. The range of twists is determined by l, h.

Display: The intmat is displayed in a diagram of the following form: with `displayCohom(A,l,h,nvars(r)-1)`;

	l	l+1	h
n:	$h^n(F(l))$	$h^n(F(l+1))$	$h^n(F(h))$
1:	$h^1(F(l))$	$h^1(F(l+1))$	$h^1(F(h))$
0:	$h^0(F(l))$	$h^0(F(l+1))$	$h^0(F(h))$
chi:	$\chi(F(l))$	$\chi(F(l+1))$	$\chi(F(h))$

A '-' in the diagram refers to a zero entry; a '*' refers to a negative entry (= dimension not yet determined). refers to a not computed dimension.

If `printlevel` ≥ 1 , step-by step timings will be printed. If `printlevel` ≥ 2 we add progress debug messages if `printlevel` ≥ 3 , even all intermediate results...

Note: This procedure is based on the Bernstein-Gel'fand-Gel'fand correspondence and on Tate resolution (see [Eisenbud, Floystad, Schreyer: Sheaf cohomology and free resolutions over exterior algebras, Trans AMS 355 (2003)]).

`sheafCohBGG(M,l,h)` does not compute all values in the above table. To determine all values of $h^i(F(d))$, $d=1..h$, use `sheafCohBGG(M,l-n,h+n)`. Experimental version. Should require less memory.

Example:

```

LIB "sheafcoh.lib";
int pl = printlevel;
int l,h, t;
//-----
// cohomology of structure sheaf on P^4:
//-----
ring r=32001,x(1..5),dp;

```

```

See also: [Section D.5.18.12 \[displayCohom\]](#), page 1624; [Section D.5.18.4 \[sheafCohBGG\]](#), page 1613.

D.5.18.8 sheafCoh

Procedure from library `sheafcoh.lib` (see [Section D.5.18 \[sheafcoh.lib\]](#), page 1609).

Usage: `sheafCoh(M,l,h)`; M module, l,h int

Assume: M is graded, and it comes assigned with an admissible degree vector as an attribute, $h \geq 1$. The basering S has $n+1$ variables.

Return: intmat, cohomology of twists of the coherent sheaf F on P^n associated to `coker(M)`. The range of twists is determined by l, h.

Display: The intmat can be displayed in a diagram of the following form: with `displayCohom(A,l,h,nvars(r)-1)`;

	l	l+1	h
n:	$h^n(F(l))$	$h^n(F(l+1))$	$h^n(F(h))$
1:	$h^1(F(l))$	$h^1(F(l+1))$	$h^1(F(h))$
0:	$h^0(F(l))$	$h^0(F(l+1))$	$h^0(F(h))$

chi: chi(F(l)) chi(F(l+1)) chi(F(h))

A '-' in the diagram refers to a zero entry.

Note: The procedure is based on local duality as described in [Eisenbud: Computing cohomology. In Vasconcelos: Computational methods in commutative algebra and algebraic geometry. Springer (1998)].

By default, the procedure uses `mres` to compute the Ext modules. If called with the additional parameter "`sres`", the `sres` command is used instead.

Example:

```
LIB "sheafcoh.lib";
//
// cohomology of structure sheaf on P^4:
//-----

D.5.18.9 sheafCoh_w

Procedure from library `sheafcoh.lib` (see [Section D.5.18 \[sheafcoh.lib\]](#), page 1609).

Usage: `sheafCoh(M,l,h)`; `M` module, `l,h` int, `w` intvec
Assume: `M` is graded by `w`, `h` ≥ 1 . The basering `S` has `n+1` variables.
Return: intmat, cohomology of twists of the coherent sheaf `F` on P^n associated to `coker(M)`. The range of twists is determined by `l, h`.
Display: The intmat can be displayed in a diagram of the following form: with `displayCohom(A,l,h,nvars(r)-1)`;

	l	l+1	h
n:	$h^n(F(l))$	$h^n(F(l+1))$	$h^n(F(h))$
1:	$h^1(F(l))$	$h^1(F(l+1))$	$h^1(F(h))$
0:	$h^0(F(l))$	$h^0(F(l+1))$	$h^0(F(h))$
chi:	$\chi(F(l))$	$\chi(F(l+1))$	$\chi(F(h))$

A '-' in the diagram refers to a zero entry.

Note: The procedure is based on local duality as described in [Eisenbud: Computing cohomology. In Vasconcelos: Computational methods in commutative algebra and algebraic geometry. Springer (1998)].
By default, the procedure uses `mres` to compute the Ext modules. If called with the additional parameter "`sres`", the `sres` command is used instead.

Example:

```
LIB "sheafcoh.lib";
//

```

See also: [Section D.5.18.10 \[dimH\]](#), page 1623; [Section D.5.18.8 \[sheafCoh\]](#), page 1620; [Section D.5.18.4 \[sheafCohBGG\]](#), page 1613.

D.5.18.10 dimH

Procedure from library `sheafcoh.lib` (see [Section D.5.18 \[sheafcoh.lib\]](#), page 1609).

Usage: `dimH(i,M,d)`; M module, i,d int

Assume: M is graded, and it comes assigned with an admissible degree vector as an attribute, $h \geq 1$, and the basering S has $n+1$ variables.

Return: int, vector space dimension of $H^i(F(d))$ for F the coherent sheaf on P^n associated to $\text{coker}(M)$.

Note: The procedure is based on local duality as described in [Eisenbud: Computing cohomology. In Vasconcelos: Computational methods in commutative algebra and algebraic geometry. Springer (1998)].

Example:

```

LIB "sheafcoh.lib";
ring R=0,(x,y,z,u),dp;
resolution T1=mres(maxideal(1),0);
module M=T1[3];
intvec v=2,2,2,2,2,2;
attrib(M,"isHomog",v);
dimH(0,M,2);
↳ 6
dimH(1,M,0);
↳ 1
dimH(2,M,1);
↳ 0
dimH(3,M,-5);
↳ 36

```

See also: [Section D.5.18.8 \[sheafCoh\]](#), page 1620; [Section D.5.18.4 \[sheafCohBGG\]](#), page 1613.

D.5.18.11 dimGradedPart

Procedure from library `sheafcoh.lib` (see [Section D.5.18 \[sheafcoh.lib\]](#), page 1609).

Usage: `dimGradedPart(M,d)`; M module, d int

Assume: M is graded, and it comes assigned with an admissible degree vector as an attribute

Return: int

Note: Output is the vector space dimension of the graded part of degree d of $\text{coker}(M)$.

Example:

```
LIB "sheafcoh.lib";
ring R=0,(x,y,z),dp;
module M=maxideal(3);
// assign compatible weight vector (here: 0)
homog(M);
↪ 1
// compute dimension of graded pieces of R/<x,y,z>^3 :
dimGradedPart(M,0);
↪ 1
dimGradedPart(M,1);
↪ 3
dimGradedPart(M,2);
↪ 6
dimGradedPart(M,3);
↪ 0
// shift grading:
attrib(M,"isHomog",intvec(2));
dimGradedPart(M,2);
↪ 1
```

D.5.18.12 displayCohom

Procedure from library `sheafcoh.lib` (see [Section D.5.18 \[sheafcoh.lib\]](#), page 1609).

Usage: `displayCohom(data,l,h,n)`; data intmat, l,h,n int

Assume: $h \geq 1$, data is the return value of `sheafCoh(M,l,h)` or of `sheafCohBGG(M,l,h)`, and the basering has $n+1$ variables.

Return: none

Note: The intmat is displayed in a diagram of the following form:

	l	l+1	h
n:	$h^n(F(l))$	$h^n(F(l+1))$	$h^n(F(h))$
1:	$h^1(F(l))$	$h^1(F(l+1))$	$h^1(F(h))$
0:	$h^0(F(l))$	$h^0(F(l+1))$	$h^0(F(h))$
chi:	$\chi(F(l))$	$\chi(F(l+1))$	$\chi(F(h))$

where F refers to the associated sheaf of M on P^n .

A '−' in the diagram refers to a zero entry, a '*' refers to a negative entry (= dimension not yet determined).

D.5.19 JMBTest.lib

Library: JMBTest.lib

Purpose: A library for Singular which performs JM basis test.

Author: Michela Ceria, email: michela.ceria@unito.it

Overview: The library performs the J-marked basis test, as described in [CR], [BCLR]. Such a test is performed via the criterion explained in [BCLR], concerning Eliahou-Kervaire polynomials (EK from now on). We point out that all the polynomials are homogeneous and they must be arranged by degree.

The fundamental steps are the following:

- construct the V_m polynomials, via the algorithm VConstructor explained in [CR];
- construct the Eliahou-Kervaire polynomials defined in [BCLR];
- reduce the Eliahou-Kervaire polynomials using the V_m 's;
- if it exist an Eliahou-Kervaire polynomial such that its reduction mod V_m is different from zero, the given one is not a J-Marked basis.

The algorithm terminates only if the ordering is ip. Anyway, the number of reduction steps is bounded.

Procedures: See also: [Section D.5.20 \[JMSConst.lib\]](#), page 1627.

D.5.19.1 Minimus

Procedure from library JMBTest.lib (see [Section D.5.19 \[JMBTest.lib\]](#), page 1625).

Usage: Minimus(L); G list, c int

Return: list: V

Notes: it returns the minimal variable generating the ideal L.
The input must be an ideal generated by variables.

Example:

```
LIB "JMBTest.lib";
ring r=0, (x,y,z), ip;
ideal I=y,x,z;
Minimus(I);
↦ x
```

D.5.19.2 Maximus

Procedure from library JMBTest.lib (see [Section D.5.19 \[JMBTest.lib\]](#), page 1625).

Usage: Maximus(L); G list, c int

Return: list: V

Notes: it returns the maximal variable generating the ideal L.
The input must be an ideal generated by variables.

Example:

```
LIB "JMBTest.lib";
ring r=0, (x,y,z), ip;
ideal I=y,x,z;
Maximus(I);
↪ z
```

D.5.19.3 StartOrderingV

Procedure from library JMBTest.lib (see [Section D.5.19 \[JMBTest.lib\]](#), page 1625).

Usage: StartOrdina(V,G); V list, G list

Return: list: R

Note: Input Vm,G. This procedure uses OrderingV to get the ordered polynomials as in [BCLR].

Example:

```
LIB "JMBTest.lib";
ring r=0, (x,y,z), ip;
jmp r1;
r1.h=z^3;
r1.t=poly(0);
jmp r2;
r2.h=z^2*y;
r2.t=poly(0);
jmp r3;
r3.h=z*y^2;
r3.t=-x^2*y;
jmp r4;
r4.h=y^5;
r4.t=poly(0);
list G2F=list(list(r1,r2,r3),list(r4));
StartOrderingV(VConst(G2F,4,basing)[1],G2F);

D.5.19.4 TestJMark

Procedure from library `JMBTest.lib` (see [Section D.5.19 \[JMBTest.lib\]](#), page 1625).

Usage: `TestJMark(G); G list`

Return: `int: i`

Note: This procedure performs J-marked basis test.
 The input is a list of J-marked polynomials (`jmp`) arranged by degree, so `G1` is a list of list.
 The output is a boolean evaluation:
 `True=1/False=0`

Example:

```

LIB "JMBTest.lib";
ring r=0, (x,y,z), ip;
jmp r1;
r1.h=z^3;
r1.t=poly(0);
jmp r2;
r2.h=z^2*y;
r2.t=poly(0);
jmp r3;
r3.h=z*y^2 ;
r3.t=-x^2*y;
jmp r4;
r4.h=y^5;
r4.t=poly(0);
list G2F=list(list(r1,r2,r3),list(r4));
TestJMark(G2F,r);
↳ NOT A BASIS
↳ 0

```

D.5.20 JMSTConst.lib

Library: `JMSTConst.lib`

Purpose: A library for Singular which constructs J-Marked Schemes.

Author: Michela Ceria, email: michela.ceria@unito.it

Overview: The library performs the J-marked computation, as described in [BCLR]. As in `JMBTest.lib` we construct the `V` polynomials and we reduce the `EK` polynomials w.r.t. them, putting the coefficients as results.

The algorithm terminates only if the ordering is `ip`. Anyway, the number of reduction steps is bounded.

Procedures: See also: [Section D.5.19 \[JMBTest.lib\], page 1625](#); [Section D.5.20 \[JMSTest.lib\], page 1627](#).

D.5.20.1 BorelCheck

Procedure from library `JMSTest.lib` (see [Section D.5.20 \[JMSTest.lib\], page 1627](#)).

Usage: `BorelCheck(Borid,r);` Borid ideal, r ring

Return: int: d

Note: Input must be a monomial ideal.
The procedure checks whether the Borel moves produce elements belonging to Borid.

Example:

```
LIB "JMSTest.lib";
ring r=0, (x,y,z),ip;
ideal Borid=y^2*z,y*z^2,z^3,y^5;
BorelCheck(Borid,r);
↪ 1
```

D.5.20.2 JMarkedScheme

Procedure from library `JMSTest.lib` (see [Section D.5.20 \[JMSTest.lib\], page 1627](#)).

Usage: `JMarkedScheme(Borid, r);` Borid ideal, r ring

Return: list: Jms

Note: This procedure performs automatically the whole construction of the J-marked scheme.

Example:

```
LIB "JMSTest.lib";
ring r=0, (x,y,z),ip;
ideal Borid=y^2*z,y*z^2,z^3,y^5;
JMarkedScheme(Borid,r);

D.6 Singularities

D.6.1 alexpoly_lib

Library: alexpoly.lib

Purpose: Resolution Graph and Alexander Polynomial

Author: Fernando Hernando Carrillo, hernando@agt.uva.es
Thomas Keilen, keilen@mathematik.uni-kl.de

Overview: A library for computing the resolution graph of a plane curve singularity f , the total multiplicities of the total transforms of the branches of f along the exceptional divisors of a minimal good resolution of f , the Alexander polynomial of f , and the zeta function of its monodromy operator.

Procedures:

D.6.1.1 resolutiongraph

Procedure from library `alexpoly.lib` (see [Section D.6.1 \[alexpoly.lib\]](#), page 1630).

Usage: `resolutiongraph(INPUT)`; INPUT poly or list

Assume: INPUT is either a REDUCED bivariate polynomial defining a plane curve singularity, or the output of `hnexpansion(f[, "ess"])`, or the list `hne` in the ring created by `hnexpansion(f[, "ess"])`, or the output of `develop(f)` resp. of `extdevelop(f,n)`, or a list containing the contact matrix and a list of integer vectors with the characteristic exponents of the branches of a plane curve singularity, or an integer vector containing the characteristic exponents of an irreducible plane curve singularity.

Return: `intmat`, the incidence matrix of the resolution graph of the plane curve defined by INPUT, where the entries on the diagonal are the weights of the vertices of the graph and a negative entry corresponds to the strict transform of a branch of the curve.

Note: In case the Hamburger-Noether expansion of the curve `f` is needed for other purposes as well it is better to calculate this first with the aid of `hnexpansion` and use it as input instead of the polynomial itself.
If you are not sure whether the INPUT polynomial is reduced or not, use `squarefree(INPUT)` as input instead.

Example:

```
LIB "alexpoly.lib";
ring r=0,(x,y),ls;
poly f1=(y2-x3)^2-4x5y-x7;
poly f2=y2-x3;
poly f3=y3-x2;
resolutiongraph(f1*f2*f3);
⇨ 1,0,1,0,0,0,0,0,1,0,
⇨ 0,2,1,0,0,0,0,0,0,0,
⇨ 1,1,3,0,1,0,0,0,0,0,

⇨ 1,0,0,0,0,0,0,1,3,1,
⇨ 0,0,0,0,0,0,0,0,1,-3
```

See also: [Section D.6.1.3 \[alexanderpolynomial\]](#), page 1633; [Section D.6.15.2 \[develop\]](#), page 1726; [Section D.6.15.1 \[hnexpansion\]](#), page 1724; [Section D.6.1.2 \[totalmultiplicities\]](#), page 1631.

D.6.1.2 totalmultiplicities

Procedure from library `alexpoly.lib` (see [Section D.6.1 \[alexpoly.lib\]](#), page 1630).

Usage: `totalmultiplicities(INPUT)`; INPUT poly or list

Assume: INPUT is either a REDUCED bivariate polynomial defining a plane curve singularity, or the output of `hnexpansion(f[, "ess"])`, or the list `hne` in the ring created by `hnexpansion(f[, "ess"])`, or the output of `develop(f)` resp. of `extdevelop(f,n)`, or a list containing the contact matrix and a list of integer vectors with the characteristic exponents of the branches of a plane curve singularity, or an integer vector containing the characteristic exponents of an irreducible plane curve singularity.

Return: list L of three integer matrices. L[1] is the incidence matrix of the resolution graph of the plane curve defined by INPUT, where the entries on the diagonal are the weights of the vertices of the graph and a negative entry corresponds to the strict transform of a branch of the curve. L[2] is an integer matrix, which has for each vertex in the graph a row and for each branch of the curve a column. The entry in position [i,j] contains the total multiplicity of the j-th branch (i.e. the branch with weight -j in L[1]) along the exceptional divisor corresponding to the i-th row in L[1]. In particular, the i-th row contains the total multiplicities of the branches of the plane curve (defined by INPUT) along the exceptional divisor which corresponds to the i-th row in the incidence matrix L[1]. L[3] is an integer matrix which contains the (strict) multiplicities of the branches of the curve along the exceptional divisors in the same way as L[2] contains the total multiplicities.

Note: The total multiplicity of a branch along an exceptional divisor is the multiplicity with which this exceptional divisor occurs in the total transform of this branch under the resolution corresponding to the resolution graph.

In case the Hamburger-Noether expansion of the curve f is needed for other purposes as well it is better to calculate this first with the aid of `hnexpansion` and use it as input instead of the polynomial itself.

If you are not sure whether the INPUT polynomial is reduced or not, use `squarefree(INPUT)` as input instead.

Example:

```
LIB "alexpoly.lib";
ring r=0,(x,y),ls;
poly f1=(y2-x3)^2-4x5y-x7;
poly f2=y2-x3;
poly f3=y3-x2;
totalmultiplicities(f1*f2*f3);

See also: [Section D.6.1.3 \[alexanderpolynomial\]](#), page 1633; [Section D.6.15.2 \[develop\]](#), page 1726; [Section D.6.15.1 \[hnexpansion\]](#), page 1724; [Section D.6.1.1 \[resolutiongraph\]](#), page 1631.

D.6.1.3 alexanderpolynomial

Procedure from library `alexpoly.lib` (see [Section D.6.1 \[alexpoly.lib\]](#), page 1630).

Usage: `alexanderpolynomial(INPUT);` INPUT poly or list

Assume: INPUT is either a REDUCED bivariate polynomial defining a plane curve singularity, or the output of `hnexpansion(f, "ess")`, or the list `hne` in the ring created by `hnexpansion(f, "ess")`, or the output of `develop(f)` resp. of `extdevelop(f, n)`, or a list containing the contact matrix and a list of integer vectors with the characteristic exponents of the branches of a plane curve singularity, or an integer vector containing the characteristic exponents of an irreducible plane curve singularity.

Create: a ring with variables `t`, `t(1)`, ..., `t(r)` (where `r` is the number of branches of the plane curve singularity `f` defined by INPUT) and ordering `ls` over the ground field of the basering.
Moreover, the ring contains the Alexander polynomial of `f` in variables `t(1)`, ..., `t(r)` (`alexpoly`), the zeta function of the monodromy operator of `f` in the variable `t` (`zeta_monodromy`), and a list containing the factors of the Alexander polynomial with multiplicities (`alexfactors`).

Return: a list, say `ALEX`, where `ALEX[1]` is the created ring

Note: to use the ring type: `def ALEXring=ALEX[i]; setring ALEXring;`
Alternatively you may use the procedure `sethnering` and type: `sethnering(ALEX, "ALEXring");`
To access the Alexander polynomial resp. the zeta function resp. the factors of the Alexander polynomial type: `alexpoly` resp. `zeta_monodromy` resp. `alexfactors`.
In case the Hamburger-Noether expansion of the curve `f` is needed for other purposes as well it is better to calculate this first with the aid of `hnexpansion` and use it as input instead of the polynomial itself.
If you are not sure whether the INPUT polynomial is reduced or not, use `squarefree(INPUT)` as input instead.

Example:

```

LIB "alexpoly.lib";
ring r=0,(x,y),ls;
poly f1=(y2-x3)^2-4x5y-x7;
poly f2=y2-x3;
poly f3=y3-x2;
list ALEX=alexanderpolynomial(f1*f2*f3);
def ALEXring=ALEX[1];

```

```

See also: [Section D.6.1.1 \[resolutiongraph\]](#), page 1631; [Section D.6.1.2 \[totalmultiplicities\]](#), page 1631.

D.6.1.4 semigroup

Procedure from library `alexpoly.lib` (see [Section D.6.1 \[alexpoly_lib\]](#), page 1630).

Usage: `semigroup(INPUT);` INPUT poly or list

Assume: INPUT is either a REDUCED bivariate polynomial defining a plane curve singularity, or the output of `hnexpansion(f, "ess")`, or the list `hne` in the ring created by `hnexpansion(f, "ess")`, or the output of `develop(f)` resp. of `extdevelop(f, n)`, or a list containing the contact matrix and a list of integer vectors with the characteristic exponents of the branches of a plane curve singularity, or an integer vector containing the characteristic exponents of an irreducible plane curve singularity.

Return: a list with three entries. The first and the second are lists v_1, \dots, v_s and w_1, \dots, w_r respectively of integer vectors such that the semigroup of the plane curve defined by the INPUT is generated by the vectors $v_1, \dots, v_s, w_1 + k \cdot e_1, \dots, w_r + k \cdot e_r$, where e_i denotes the i -th standard basis vector and k runs through all non-negative integers. The third entry is the conductor of the plane curve singularity. Note that r

is the number of branches of the plane curve singularity and integer vectors thus have size r .

Note: If the output is zero this means that the curve has one branch and is regular. In the reducible case the set of generators may not be minimal.
If you are not sure whether the INPUT polynomial is reduced or not, use `squarefree(INPUT)` as input instead.

Example:

```
LIB "alexpoly.lib";
ring r=0,(x,y),ls;
// Irreducible Case
semigroup((x2-y3)^2-4x5y-x7);
⇒ [1]:
⇒ [1]:
⇒ 4
⇒ [2]:

⇒ [3]:
⇒ 12,13,26
⇒ [3]:
⇒ 20,21,41
```

See also: [Section D.6.1.1 \[resolutiongraph\]](#), page 1631; [Section D.6.1.2 \[totalmultiplicities\]](#), page 1631.

D.6.1.5 proximitymatrix

Procedure from library `alexpoly.lib` (see [Section D.6.1 \[alexpoly_lib\]](#), page 1630).

Usage: `proximitymatrix(INPUT)`; INPUT poly or list or intmat

Assume: INPUT is either a REDUCED bivariate polynomial defining a plane curve singularity, or the output of `hnexpansion(f[,"ess"])`, or the list `hne` in the ring created by `hnexpansion(f[,"ess"])`, or the output of `develop(f)` resp. of `extdevelop(f,n)`, or a list containing the contact matrix and a list of integer vectors with the characteristic exponents of the branches of a plane curve singularity, or an integer vector containing the characteristic exponents of an irreducible plane curve singularity, or the resolution graph of a plane curve singularity (i.e. the output of `resolutiongraph` or the first entry in the output of `totalmultiplicities`).

Return: list, of three integer matrices. The first one is the proximity matrix of the plane curve defined by the INPUT, i.e. the entry i,j is 1 if the infinitely near point corresponding to row i is proximate to the infinitely near point corresponding to row j . The second integer matrix is the incidence matrix of the resolution graph of the plane curve. The entry on the diagonal in row i is $-s-1$ if s is the number of points proximate to the infinitely near point corresponding to the i th row in the matrix. The third integer matrix is the incidence matrix of the Enriques diagram of the plane curve singularity, i.e. each row corresponds to an infinitely near point in the minimal standard resolution, including the strict transforms of the branches, the diagonal element gives the level of the point, and the entry i,j is -1 if row i is proximate to row j .

Note: In case the Hamburger-Noether expansion of the curve f is needed for other purposes as well it is better to calculate this first with the aid of `hnexpansion` and use it as input instead of the polynomial itself.

If you are not sure whether the INPUT polynomial is reduced or not, use `squarefree(INPUT)` as input instead.

If the input is a smooth curve, then the output will consist of three one-by-one zero matrices.

For the definitions of the computed objects see e.g. the book Eduardo Casas-Alvero, Singularities of Plane Curves.

Example:

```
LIB "alexpoly.lib";
ring r=0,(x,y),ls;
poly f1=(y2-x3)^2-4x5y-x7;
poly f2=y2-x3;
poly f3=y3-x2;
list proximity=proximitymatrix(f1*f2*f3);
/// The proximity matrix P ///
print(proximity[1]);
⇒      1      0      0      0      0      0      0      0      0      0
⇒     -1      1      0      0      0      0      0      0      0      0
⇒     -1     -1      1      0      0      0      0      0      0      0

D.6.1.6 multseq2charexp

Procedure from library `alexpoly.lib` (see [Section D.6.1 \[alexpoly_lib\]](#), page 1630).

Assume: The input is an intvec, which contains the multiplicity sequence of an irreducible plane curve singularity .

Return: An intvec, which contains the sequence of characteristic exponents of the irreducible plane curve singularity defined by v.

Example:

```

LIB "alexpoly.lib";
intvec v=2,1,1;
multseq2charexp(v);
⇒ 2,3
intvec v1=4,2,2,1,1;
multseq2charexp(v1);
⇒ 4,6,7

```

D.6.1.7 charexp2multseq

Procedure from library `alexpoly.lib` (see [Section D.6.1 \[alexpoly_lib\]](#), page 1630).

Usage: `charexp2multseq(v)`, v intvec

Assume: v contains the characteristic exponents of an irreducible plane curve singularity

Return: intvec, the multiplicity sequence of the plane curve singularity

Note: If the curve singularity is smooth, then the multiplicity sequence is empty. This is expressed by returning zero.

Example:

```

LIB "alexpoly.lib";
charexp2multseq(intvec(28,64,66,77));
⇒ 28,28,8,8,8,4,4,2,2,2,2,2,2,2,1,1

```

See also: [Section D.6.1.3 \[alexanderpolynomial\]](#), page 1633; [Section D.6.15.6 \[invariants\]](#), page 1731; [Section D.6.1.1 \[resolutiongraph\]](#), page 1631; [Section D.6.1.2 \[totalmultiplicities\]](#), page 1631.

D.6.1.8 charexp2generators

Procedure from library `alexpoly.lib` (see [Section D.6.1 \[alexpoly.lib\]](#), page 1630).

Usage: `charexp2generators(v)`, v intvec

Assume: v contains the characteristic exponents of an irreducible plane curve singularity

Return: intvec, the minimal set of generators of the semigroup of the plane curve singularity

Example:

```
LIB "alexpoly.lib";
charexp2generators(intvec(28,64,66,77));
⇒ 28,64,450,911
```

See also: [Section D.6.1.3 \[alexanderpolynomial\]](#), page 1633; [Section D.6.15.6 \[invariants\]](#), page 1731; [Section D.6.1.1 \[resolutiongraph\]](#), page 1631; [Section D.6.1.2 \[totalmultiplicities\]](#), page 1631.

D.6.1.9 charexp2inter

Procedure from library `alexpoly.lib` (see [Section D.6.1 \[alexpoly.lib\]](#), page 1630).

Usage: `charexp2inter(contact,charexp)`, contact matrix, charexp list

Assume: charexp contains the integer vectors of characteristic exponents of the branches of a plane curve singularity, and contact is their contact matrix

Return: intmat, the matrix intersection multiplicities of the branches

Example:

```
LIB "alexpoly.lib";
ring r=0,(x,y),ds;
list INV=invariants((x2-y3)*(x3-y2)*((x2-y3)^2-4x5y-x7));
intmat contact=INV[4][1];
list charexp=INV[1][1],INV[2][1],INV[3][1];
// The intersection matrix is INV[4][2].
print(INV[4][2]);
⇒      0      4      8
⇒      4      0     17
⇒      8     17      0
// And it is calculated as ...
print(charexp2inter(contact,charexp));
⇒      0      4      8
⇒      4      0     17
⇒      8     17      0
```

See also: [Section D.6.15.6 \[invariants\]](#), page 1731; [Section D.6.1.1 \[resolutiongraph\]](#), page 1631; [Section D.6.1.4 \[semigroup\]](#), page 1634; [Section D.6.1.2 \[totalmultiplicities\]](#), page 1631.

D.6.1.10 charexp2conductor

Procedure from library `alexpoly.lib` (see [Section D.6.1 \[alexpoly.lib\]](#), page 1630).

Assume: v contains the characteristic exponents of an irreducible plane curve singularity

Return: int, the conductor of the plane curve singularity

Note: If the curve singularity is smooth, the conductor is zero.

Example:

```
LIB "alexpoly.lib";
charexp2conductor(intvec(2,3)); // A1-Singularity
↳ 2
charexp2conductor(intvec(28,64,66,77));
↳ 1718
```

See also: [Section D.6.15.6 \[invariants\]](#), page 1731; [Section D.6.1.1 \[resolutiongraph\]](#), page 1631; [Section D.6.1.4 \[semigroup\]](#), page 1634; [Section D.6.1.2 \[totalmultiplicities\]](#), page 1631.

D.6.1.11 charexp2poly

Procedure from library `alexpoly.lib` (see [Section D.6.1 \[alexpoly_lib\]](#), page 1630).

Assume: `v` an intvec containing the characteristic exponents of an irreducible plane curve singularity. `a` a vector containing the coefficients of a parametrization given by $x(t)=x^v[1]$, $y(t)=a(1)t^v[2]+\dots+a[n-1]t^v[n]$, i.e. the entries of `a` are of type number.

Return: A polynomial `f` in the first two variables of the basering, such that `f` defines an irreducible plane curve singularity with characteristic exponents `v`.

Note: The entries in `a` should be of type number and the vector `v` should be the sequence of characteristic exponents of an irreducible plane curve singularity in order to get a sensible result,

Example:

```
LIB "alexpoly.lib";
ring r=0,(x,y),dp;
intvec v=8,12,14,17;
vector a=[1,1,1];
poly f=charexp2poly(v,a);
f;
↳ -x17+8x16-20x15+17x14-16x13y+12x12y2-2x13+32x12y-16x11y2-8x10y3+x12-8x11y\
+20x10y2-16x9y3-4x9y2+16x8y3-2x7y4-8x6y5+6x6y4-8x5y5-4x3y6+y8
invariants(f)[1][1]; // The characteristic exponents of f.
↳ 8,12,14,17
```

See also: [Section D.6.1.7 \[charexp2multseq\]](#), page 1638; [Section D.6.1.6 \[multseq2charexp\]](#), page 1638.

D.6.1.12 tau_es2

Procedure from library `alexpoly.lib` (see [Section D.6.1 \[alexpoly_lib\]](#), page 1630).

Usage: `tau_es2(INPUT)`; `INPUT` poly or list

Assume: `INPUT` is either a REDUCED bivariate polynomial defining a plane curve singularity, or the output of `hnexpansion(f, "ess")`, or the list `hne` in the ring created by `hnexpansion(f, "ess")`, or the output of `develop(f)` resp. of `extdevelop(f,n)`, or a list containing the contact matrix and a list of integer vectors with the characteristic exponents of the branches of a plane curve singularity, or an integer vector containing the characteristic exponents of an irreducible plane curve singularity.

Return: int, the equisingular Tjurina number of `f`, i. e. the codimension of the μ -constant stratum in the semiuniversal deformation of `f`, where μ is the Milnor number of `f`.

Note: The equisingular Tjurina number is calculated with the aid of a Hamburger-Noether expansion, which is the hard part of the calculation.

In case the Hamburger-Noether expansion of the curve f is needed for other purposes as well it is better to calculate this first with the aid of `hnexpansion` and use it as input instead of the polynomial itself.

If you are not sure whether the INPUT polynomial is reduced or not, use `squarefree(INPUT)` as input instead.

Example:

```
LIB "alexpoly.lib";
ring r=0,(x,y),ls;
poly f1=y2-x3;
poly f2=(y2-x3)^2-4x5y-x7;
poly f3=y3-x2;
tau_es2(f1);
  ↪ 2
tau_es2(f2);
  ↪ 14
tau_es2(f1*f2*f3);
  ↪ 49
```

See also: [Section D.6.15.2 \[develop\], page 1726](#); [Section D.6.12 \[equising_lib\], page 1701](#); [Section D.6.15.1 \[hnexpansion\], page 1724](#); [Section D.6.12.1 \[tau_es\], page 1702](#); [Section D.6.1.2 \[totalmultiplicities\], page 1631](#).

D.6.2 arcpoint_lib

Library: arcpoint.lib

Purpose: Truncations of arcs at a singular point

Author: Nadine Cremer cremer@mathematik.uni-kl.de

Overview: An arc is given by a power series in one variable, say t , and truncating it at a positive integer i means cutting the t -powers $> i$. The set of arcs truncated at order $<bound>$ is denoted $Tr(i)$. An algorithm for computing these sets (which happen to be constructible) is given in [Lejeune-Jalabert, M.: Courbes tracées sur un germe d'hypersurface, American Journal of Mathematics, 112 (1990)]. Our procedures for computing the locally closed sets contributing to the set of truncations rely on this algorithm.

Procedures:

D.6.2.1 nashmult

Procedure from library `arcpoint.lib` (see [Section D.6.2 \[arcpoint_lib\], page 1641](#)).

Usage: `nashmult(f,bound)`; f polynomial, $bound$ positive integer

Create: `allsteps`:

a list containing all relevant locally closed sets
up to order $<bound>$ and their sequences of
Nash Multiplicities

`setstep`:

list of relevant locally closed sets
obtained from sequences of length $bound+1$

Return: ring, original basering with additional variables t and coefficients up to $t^{\text{<bound>}}$

Example:

```
LIB "arcpoint.lib";
ring r=0,(x,y,z),dp;
poly f=z4+y3-x2;
def R=nashmult(f,2);
setring R;
allsteps;

⇨       _[1]=1
```

D.6.2.2 removepower

Procedure from library `arcpoint.lib` (see [Section D.6.2 \[arcpoint.lib\]](#), page 1641).

Usage: `removepower(I); I ideal`

Return: ideal defining the same zeroset as I : if any generator of I is a power of one single variable, replace it by the respective variable

Example:

```
LIB "arcpoint.lib";
ring r=0,(x,y,z),dp;
```

```

ideal I = x3,y+z2-x2;
I;
↪ I[1]=x3
↪ I[2]=-x2+z2+y
removepower(I);
↪ _[1]=x
↪ _[2]=-x2+z2+y

```

See also: [Section D.6.2.3 \[idealsimplify\], page 1643](#).

D.6.2.3 idealsimplify

Procedure from library `arcpoint.lib` (see [Section D.6.2 \[arcpoint.lib\], page 1641](#)).

Usage: `idealsimplify(I,m)`; I ideal, m int

Assume: procedure is stable for sufficiently large m

Return: ideal defining the same zeroset as I: replace generators of I by the generator modulo other generating elements

Example:

```

LIB "arcpoint.lib";
ring r=0,(x,y,z),dp;
ideal I = x3,y+z2-x2;
I;
↪ I[1]=x3
↪ I[2]=-x2+z2+y
idealsimplify(I,10);
↪ _[1]=x
↪ _[2]=z2+y

```

D.6.2.4 equalJinI

Procedure from library `arcpoint.lib` (see [Section D.6.2 \[arcpoint.lib\], page 1641](#)).

Usage: `equalJinI(I,J)`; (I,J ideals)

Assume: J contained in I and both I and J have been processed with `idealsimplify` before

Return: 1, if I=J, 0 otherwise

Example:

```

LIB "arcpoint.lib";
ring r=0,(x,y,z),dp;
ideal I = x,y+z2;
ideal J1= x;
ideal J2= x,y+z2;
equalJinI(I,J1);
↪ 0
equalJinI(I,J2);
↪ 1

```

See also: [Section D.6.2.3 \[idealsimplify\], page 1643](#).

D.6.3 arnoldclassify_lib

Library: arnoldClassify.lib

Purpose: Arnol'd Classifier of Singularities

Author: Eva Maria Hemmerling, ehemmerl@rhrk.uni-kl.de

Overview: A library for classifying isolated hypersurface singularities from the list of V.I. Arnol'd w.r.t. right equivalence up to corank 2. The method relies on Baciuc's list of Milnor codes and Newton's rotating ruler method to distinguish the Y- and Z- singularities.

Procedures: See also: [Section D.15.1 \[arnold_lib\], page 2277](#); [Section D.6.4 \[classify_lib\], page 1650](#); [Section D.6.19 \[realclassify_lib\], page 1750](#).

D.6.3.1 arnoldListAllSeries

Procedure from library arnoldclassify.lib (see [Section D.6.3 \[arnoldclassify_lib\], page 1644](#)).

Usage: arnoldListAllSeries();

Return: list of names of singularity series listed by Arnol'd up to corank 2

Example:

```
LIB "arnoldclassify.lib";
arnoldListAllSeries();
⇒ [1]:
⇒ A[k]
⇒ [2]:
⇒ D[k]
⇒ [3]:
⇒ E[6k]
⇒ [4]:
⇒ E[6k+1]
⇒ [5]:
⇒ E[6k+2]
⇒ [6]:
⇒ J[k,0]
⇒ [7]:
⇒ J[k,r]
⇒ [8]:
⇒ W[12k]
⇒ [9]:
⇒ W[12k+1]
```

```

⇒ [10] :
⇒      W[12k+5]
⇒ [11] :
⇒      W[12k+6]
⇒ [12] :
⇒      W[k,0]
⇒ [13] :
⇒      W[k,r]
⇒ [14] :
⇒      W#[k,2r]
⇒ [15] :
⇒      W#[k,2r-1]
⇒ [16] :
⇒      X[k,0]
⇒ [17] :
⇒      X[k,r]
⇒ [18] :
⇒      Y[k,r,s]
⇒ [19] :
⇒      Z[k,r]
⇒ [20] :
⇒      Z[k,r,s]
⇒ [21] :
⇒      Z[1,6r+11]
⇒ [22] :
⇒      Z[1,6r+12]
⇒ [23] :
⇒      Z[1,6r+13]
⇒ [24] :
⇒      Z[k,12k+6r]
⇒ [25] :
⇒      Z[k,12k+6r+1]
⇒ [26] :
⇒      Z[k,12k+6r-1]

```

D.6.3.2 arnoldShowSeries

Procedure from library `arnoldclassify.lib` (see [Section D.6.3 \[arnoldclassify.lib\]](#), page 1644).

Usage: `arnoldShowSeries(S);` S string

Assume: S is the name of a singularity series listed by `arnoldListAllSeries()`.

Return: data of the singularity series S of type `singseries` including

- Milnor number of S,
- Corank of S,
- Milnor code of S (see [Bac01]),
- normal form of S as string with parameters k,r,s and a,b,c,d,
- restrictions on parameters in the normal form in SINGULAR syntax,
- normal form with special (valid) parameters.

Example:

```

LIB "arnoldclassify.lib";
arnoldShowSeries("Z[k,12k+6r]");
⇒ Series=Z[k,12k+6r]

```

```

⇒ NormalForm=(x + a(y)*y^k)*(x^3 + x*y^(2*k+2*r+1) +
⇒          b(y)* y^(3*k+3*r+2))
⇒ SpecialForm=(x + y^k)*(x^3 + x*y^(2*k+2*r+1) +y^(3*k+3*r+2))
⇒ Modality=3*k+r-2
⇒ Corank=2
⇒ MilnorNumber=12*k+6r
⇒ MilnorCode=1,1,2k-1,2k-1+2*r,2k+2*r
⇒ Restrictions= (k>1)&&(r>=0)&&(deg(a)<=(k-2))&&(jet(a,0)!=0)&&
⇒          (jet(b,0)!=0)&&(deg(b)<=(2*k+r-2))

```

D.6.3.3 arnoldNormalForm

Procedure from library `arnoldclassify.lib` (see [Section D.6.3 \[arnoldclassify.lib\], page 1644](#)).

Usage: `arnoldNormalForm(S [, l])`, S string or singclass, l list

Assume: If S is of type string, then S is the name of a singularity series as listed by `arnoldListAllSeries()` and l may contain suitable integer parameters k,r,s. Otherwise S of type singclass is a singularity class from Arnol'd's list. Optional suitable polynomial parameters a,b,c,d can be appended to l. If a,b,c,d are not given, valid values are chosen automatically.

Return: string NF is the normal form of the series S if no parameters given, or poly NF is the normal form of the class S with parameters k,r,s.

Example:

```

LIB "arnoldclassify.lib";
ring R = 0, (x,y), ds;
poly a,b,c,d;
a= 1+y2;
c= 3+y;
int k = 5;
int r = 4;
int s = 3;
arnoldNormalForm ("W[12k+1]", k,r,s,a,b,c,d);
⇒ x4+x2y11+x2y13+xy16+3y22+y23
def f = _;
def sf = arnoldClassify( f );
arnoldNormalForm(sf, a,b,c,d);
⇒ x4+x2y11+x2y13+xy16+3y22+y23
arnoldNormalForm("W[12k+1]");
⇒ x4+x*y^(3*k+1)+y^(4*k+2)
arnoldNormalForm(sf);
⇒ x4+xy16+y22

```

D.6.3.4 arnoldClassify

Procedure from library `arnoldclassify.lib` (see [Section D.6.3 \[arnoldclassify.lib\], page 1644](#)).

Usage: `arnoldClassify(f)`; f poly

Assume: The basering is local of characteristic 0 and f defines an isolated singularity from Arnol'd's list of corank at most 2.

Compute: singularity class with respect to right equivalence and invariants used in the process of classification

Return: Singularity class of f of type `singclass` containing

- name of singularity series as listed by `arnoldListAllSeries()`,
- name of singularity class,
- parameters k, r, s defining the singularity class, -1 if not used,
- modality, corank, Milnor number, determinacy,
- Tjurina number, -2 if not computed, -1 if infinite,
- Milnor code, -1 if not computed,
- normal form of the singularity series from Arnol'd's list,
- restrictions on parameters as string in SINGULAR syntax.

Example:

```
LIB "arnoldclassify.lib";
ring r = 0,(x,y),ds;
int k = random(3,10);
poly g = x4 + x2*y^(2*k+1)+x*y^(3*k+1)+ y^(4*k +1);
arnoldClassify(g);
⇒ Series=W[12k]
⇒ Class=W[60]
⇒ k=5
⇒ r=-1
⇒ s=-1
⇒ Modality=13
⇒ Corank=2
⇒ Milnor=60
⇒ Determinacy=29
⇒ Tjurina=-2
⇒ MilnorCode=1,1,10,9,9
⇒ NormalForm=x4+a(y)*x*y^(3*k+1)+c(y)*x^2*y^(2*k+1)+y^(4*k+1)
⇒ Restrictions=(k>=1)&&(k>1||a==0)&&(deg(a)<=(k-2))&&
⇒ (deg(c)<=(2*k-2))
map phi=r,y-x^2,x+y;
phi(g);
⇒ y4-4x2y3+6x4y2-4x6y+x8+x11y2+11x10y3+55x9y4+165x8y5+330x7y6+462x6y7+462x5\

arnoldClassify(phi(g));
⇒ Series=W[12k]
⇒ Class=W[60]
⇒ k=5
⇒ r=-1
⇒ s=-1
⇒ Modality=13
⇒ Corank=2
⇒ Milnor=60
```

```

⇒ Determinacy=29
⇒ Tjurina=-2
⇒ MilnorCode=1,1,10,9,9
⇒ NormalForm=x4+a(y)*x*y^(3*k+1)+c(y)*x^2*y^(2*k+1)+y^(4*k+1)
⇒ Restrictions=(k>=1)&&(k>1||a==0)&&(deg(a)<=(k-2))&&
    (deg(c)<=(2*k-2))
ring C = (0,i), (x,y), ds;
minpoly = i2 + 1;
poly f =(x2+y2)^2+x5;
arnoldClassify(f);
⇒ Series=Y[1,r,s]
⇒ Class=Y[1,1,1]
⇒ k=1
⇒ r=1
⇒ s=1
⇒ Modality=1
⇒ Corank=2
⇒ Milnor=11
⇒ Determinacy=5
⇒ Tjurina=-2
⇒ MilnorCode=1,1,1,2,1
⇒ NormalForm= x^(4+r)+ a(y)*x2*y2 + y^(4+s)
⇒ Restrictions=(deg(a)==0)&&(jet(a,0)!=0)&&(1<=s)&&(s<=r)

```

D.6.3.5 arnoldClassify_to_string

Procedure from library `arnoldclassify.lib` (see [Section D.6.3 \[arnoldclassify.lib\]](#), page 1644).

Usage: `arnoldClassify_to_string (f); f poly`

Assume: The basering is local of characteristic 0 and f defines an isolated singularity from Arnol'd's list of corank at most 2.

Compute: singularity class with respect to right equivalence and invariants used in the process of classification

Return: string: separated by |:

- name of singularity series as listed by `arnoldListAllSeries()`,
- name of singularity class,
- parameters k, r, s defining the singularity class, -1 if not used,
- modality, corank, Milnor number, determinacy,
- Tjurina number, -2 if not computed, -1 if infinite,
- Milnor code, -1 if not computed,
- normal form of the singularity series from Arnol'd's list,
- restrictions on parameters as string in SINGULAR syntax.

Example:

```

LIB "arnoldclassify.lib";
ring r = 0,(x,y),ds;
int k = random(3,10);
poly g = x4 + x2*y^(2*k+1)+x*y^(3*k+1)+ y^(4*k +1);
arnoldClassify_to_string(g);
⇒ (k>=1)&&(k>1||a==0)&&(deg(a)<=(k-2))&&
    (deg(c)<=(2*k-2))|x4+a(y)*x*y^(3*k+1)+c(y)*x^2*y^(2*k+1)+y^(4*k+1)\
    )|1,1,10,9,9|-2|29|60|2|13|-1|-1|W[60]|W[12k]

```

D.6.3.6 arnoldCorank

Procedure from library `arnoldclassify.lib` (see [Section D.6.3 \[arnoldclassify.lib\], page 1644](#)).

Usage: `arnoldCorank(f);` f poly

Assume: basering is local, f in `maxideal(2)` has isolated critical point at 0

Return: corank of the Hessian matrix of f

Example:

```
LIB "arnoldclassify.lib";
ring r=0,(x,y,z),ds;
poly f=(x2+3y-2z)2+xyz-(x-y3+x2*z3)3;
arnoldCorank(f);
↦ 2
```

D.6.3.7 arnoldDeterminacy

Procedure from library `arnoldclassify.lib` (see [Section D.6.3 \[arnoldclassify.lib\], page 1644](#)).

Usage: `arnoldDeterminacy(I[, m];` I poly or ideal, m int.

Assume: the basering is local, I is the Jacobian ideal of a polynomial f with isolated critical point at 0, m is the Milnor number of f

Compute: determinacy bound k for f w.r.t. right equivalence

Return: integer k s.th. f is right- k -determined, -1 for infinity

Note: uses [Cor. A.9.7,GP12]

Example:

```
LIB "arnoldclassify.lib";
ring r=0,(x,y),ds;
poly f=x3+xy3;
ideal I=std(jacob(f));
int k=arnoldDeterminacy(I);
print(k);
↦ 5
```

D.6.3.8 arnoldMilnorCode

Procedure from library `arnoldclassify.lib` (see [Section D.6.3 \[arnoldclassify.lib\], page 1644](#)).

Usage: `arnoldMilnorCode(f[,e]);` f poly, e int

Assume: basering is local, f has isolated critical point at 0

Compute: Milnor code of f consisting of the numbers of successive repetitions of coefficients of the 2nd Hilbert series of basering/ $(\text{jacob}(f)^e)$, see [Bac01].

Return: Milnor code of f as intvec where $e=1$ by default

Example:

```
LIB "arnoldclassify.lib";
ring r=0,(x,y,z),ds;
poly f=x2y+y3+z2;
arnoldMilnorCode(f);
↦ 1,1,1
```

```

arnoldMilnorCode(f,2);
 $\mapsto 1,1,2,1$ 
// a big second argument may result in memory overflow

```

D.6.3.9 arnoldMorseSplit

Procedure from library `arnoldclassify.lib` (see [Section D.6.3 \[arnoldclassify.lib\]](#), page 1644).

Usage: `arnoldMorseSplit(f); f poly`

Assume: base ring is local, `f` in `maxideal(2)` has isolated critical point at 0

Compute: result of Splitting Lemma applied to `f`

Return: polynomial `g` in `maxideal(3)` right equivalent to `f`

Example:

```

LIB "arnoldclassify.lib";
ring r=0,(x,y,z),ds;
export r;
poly f=(x2+3y-2z)^2+xyz-(x-y3+x2*z3)^3;
poly g=arnoldMorseSplit(f);
g;
 $\mapsto 3/2x2y-y3$ 

```

D.6.4 classify.lib

Library: `classify.lib`

Purpose: Arnold Classifier of Singularities

Author: Kai Krueger, krueger@mathematik.uni-kl.de

Overview: A library for classifying isolated hypersurface singularities w.r.t. right equivalence, based on the determinator of singularities by V.I. Arnold.

Procedures: See also: [Section D.6.19 \[realclassify.lib\]](#), page 1750.

D.6.4.1 basicinvariants

Procedure from library `classify.lib` (see [Section D.6.4 \[classify.lib\]](#), page 1650).

Usage: `basicinvariants(f); f = poly`

Compute: Compute basic invariants of `f`: an upper bound `d` for the determinacy, the milnor number `mu` and the corank `c` of `f`

Return: intvec: `d, mu, c`

Example:

```

LIB "classify.lib";
ring r=0,(x,y,z),ds;
basicinvariants((x2+3y-2z)^2+xyz-(x-y3+x2*z3)^3);
 $\mapsto 5,4,2$ 

```

D.6.4.2 classify

Procedure from library `classify.lib` (see [Section D.6.4 \[classify.lib\]](#), page 1650).

Usage: `classify(f); f=poly`

Compute: normal form and singularity type of f with respect to right equivalence, as given in the book "Singularities of differentiable maps, Volume I" by V.I. Arnold, S.M. Gusein-Zade, A.N. Varchenko

Return: normal form of f , of type `poly`

Remark: This version of `classify` is only beta. Please send bugs and comments to: "Kai Krueger" <krueger@mathematik.uni-kl.de>
Be sure to have at least Singular version 1.0.1.

Note: type `init_debug(n); (0 <= n <= 10)` in order to get intermediate information, higher values of n give more information.
The proc creates several global objects with names all starting with `@`, hence there should be no name conflicts.

Example:

```
LIB "classify.lib";
ring r=0,(x,y,z),ds;
poly f=(x2+3y-2z)^2+xyz-(x-y3+x2*z3)^3;
classify(f);
⇒ About the singularity :

```

D.6.4.3 corank

Procedure from library `classify.lib` (see [Section D.6.4 \[classify.lib\]](#), page 1650).

Usage: `corank(f); f=poly`

Return: the corank of the Hessian matrix of `f`, of type `int`

Remark: `corank(f)` is the number of variables occurring in the residual singularity after applying 'morsesplit' to `f`

Example:

```

LIB "classify.lib";
ring r=0,(x,y,z),ds;
poly f=(x2+3y-2z)2+xyz-(x-y3+x2*z3)3;
corank(f);
⇒ 2

```

D.6.4.4 Hcode

Procedure from library `classify.lib` (see [Section D.6.4 \[classify.lib\]](#), page 1650).

Usage: `Hcode(v); v=intvec`

Return: `intvec`, coding `v` according to the number of successive repetitions of an entry

Example:

```

LIB "classify.lib";
intvec v1 = 1,3,5,5,2;
Hcode(v1);

```

```

⇒ 1,0,1,0,2,0,0,1,0
intvec v2 = 1,2,3,4,4,4,4,4,4,3,2,1;
Hcode(v2);
⇒ 1,1,1,7,1,1,1

```

D.6.4.5 init_debug

Procedure from library `classify.lib` (see [Section D.6.4 \[classify.lib\], page 1650](#)).

Usage: `init_debug([level]); level=int`

Compute: Set the global variable `@DeBug` to level. The variable `@DeBug` is used by the function `debug_log(level, list of strings)` to know when to print the list of strings. `init_debug()` reports only changes of `@DeBug`.

Note: The procedure `init_debug(n)`; is useful as trace-mode. `n` may range from 0 to 10, higher values of `n` give more information.

Example:

```

LIB "classify.lib";
init_debug();
debug_log(1,"no trace information printed");
init_debug(1);
⇒ Debugging level change from 0 to 1
debug_log(1,"some trace information");
⇒ some trace information
init_debug(2);
⇒ Debugging level change from 1 to 2
debug_log(2,"nice for debugging scripts");
⇒ Debug:(2): nice for debugging scripts
init_debug(0);
⇒ Debugging switched off.

```

D.6.4.6 internalfunctions

Procedure from library `classify.lib` (see [Section D.6.4 \[classify.lib\], page 1650](#)).

Usage: `internalfunctions();`

Return: nothing, display names of internal procedures of `classify.lib`

Example:

```

LIB "classify.lib";
internalfunctions();
⇒ Internal functions for the classification using Arnold's method,
⇒ the function numbers correspond to numbers in Arnold's classifier:
⇒ Klassifiziere(poly f); //determine the type of the singularity f
⇒ Funktion1bis (poly f, list cstn)
⇒ Funktion3 (poly f, list cstn)
⇒ Funktion6 (poly f, list cstn)
⇒ Funktion13 (poly f, list cstn)
⇒ Funktion17 (poly f, list cstn)
⇒ Funktion25 (poly f, list cstn)
⇒ Funktion40 (poly f, list cstn, int k)
⇒ Funktion47 (poly f, list cstn)
⇒ Funktion50 (poly f, list cstn)

```

```

⇒ Funktion58 (poly fin, list cstn)
⇒ Funktion59 (poly f, list cstn)
⇒ Funktion66 (poly f, list cstn)
⇒ Funktion82 (poly f, list cstn)
⇒ Funktion83 (poly f, list cstn)
⇒ Funktion91 (poly f, list cstn, int k)
⇒ Funktion92 (poly f, list cstn, int k)
⇒ Funktion93 (poly f, list cstn, int k)
⇒ Funktion94 (poly f, list cstn, int k)
⇒ Funktion95 (poly f, list cstn, int k)
⇒ Funktion96 (poly f, list cstn, int k)
⇒ Funktion97 (poly f, list cstn)
⇒ Isomorphie_s82_x (poly f, poly fk, int k)
⇒ Isomorphie_s82_z (poly f, poly fk, int k)
⇒ Isomorphie_s17 (poly f, poly fk, int k, int ct)
⇒ printresult (string f,string typ,int Mu,int m,int corank,int K)
⇒
⇒   Internal functions for the classification by invariants:
⇒   Cubic (poly f)
⇒   parity (int e)           //return the parity of e
⇒   HKclass (intvec i)
⇒   HKclass3( intvec i, string SG_Typ, int cnt)
⇒   HKclass3_teil_1 (intvec i, string SG_Typ, int cnt)
⇒   HKclass5 (intvec i, string SG_Typ, int cnt)
⇒   HKclass5_teil_1 (intvec i, string SG_Typ, int cnt)
⇒   HKclass5_teil_2 (intvec i, string SG_Typ, int cnt)
⇒   HKclass7 (intvec i, string SG_Typ, int cnt)
⇒   HKclass7_teil_1 (intvec i, string SG_Typ, int cnt)
⇒
⇒   Internal functions for the Morse-splitting lemma:
⇒   Morse(poly fi, int K, int corank) //splitting lemma itself
⇒   Coeffs (list #)
⇒   Coeff
⇒
⇒   Internal functions providing tools:
⇒   ReOrder(poly f)
⇒   Singularitaet(string typ,int k,int r,int s,poly a,poly b,poly c,poly d)
⇒   RandomPolyK
⇒   Faktorisiere(poly f, poly g, int p, int k)   compute g = (ax+by^k)^p
⇒   Teile(poly f, poly g);                       //divides f by g
⇒   GetRf(poly f, int n);
⇒   Show(poly f);
⇒   checkring();
⇒   DecodeNormalFormString(string s);
⇒   Setring(int n, string ringname);
⇒

```

D.6.4.7 milnorcode

Procedure from library `classify.lib` (see [Section D.6.4 \[classify.lib\]](#), page 1650).

Usage: `milnorcode(f[e]); f=poly, e=int`

Return: intvec, coding the Hilbert function of the e -th Milnor algebra of f , i.e. of $\text{basering}/(\text{jacob}(f)^e)$ (default $e=1$), according to `proc Hcode`

Example:

```
LIB "classify.lib";
ring r=0,(x,y,z),ds;
poly f=x2y+y3+z2;
milnorcode(f);
↪ 1,1,1
milnorcode(f,2); // a big second argument may result in memory overflow
↪ 1,0,1,0,2,0,0,1,0
```

D.6.4.8 morsesplit

Procedure from library `classify.lib` (see [Section D.6.4 \[classify.lib\]](#), page 1650).

Usage: `morsesplit(f); f=poly`

Return: Normal form of f in M^3 after application of the splitting lemma

Compute: apply the splitting lemma (generalized Morse lemma) to f

Example:

```
LIB "classify.lib";
ring r=0,(x,y,z),ds;
export r;
init_debug(1);
↪ Debugging level is set to 1
poly f=(x2+3y-2z)^2+xyz-(x-y3+x2*z3)^3;
poly g=morsesplit(f);
↪ Residual singularity f= -x3+3/2xy2+1/2x3y-1/16x2y2+3x2y3
g;
↪ -x3+3/2xy2+1/2x3y-1/16x2y2+3x2y3
```

D.6.4.9 quickclass

Procedure from library `classify.lib` (see [Section D.6.4 \[classify.lib\]](#), page 1650).

Usage: `quickclass(f); f=poly`

Return: Normal form of f in Arnold's list

Remark: try to determine the normal form of f by invariants, mainly by computing the Hilbert function of the Milnor algebra, no coordinate change is needed (see also `proc 'milnorcode'`).

Example:

```
LIB "classify.lib";
ring r=0,(x,y,z),ds;
poly f=(x2+3y-2z)^2+xyz-(x-y3+x2*z3)^3;
quickclass(f);
↪ Singularity R-equivalent to : D[k]=D[4]
↪ normal form : z2+x2y+y3
↪ z2+x2y+y3
```

D.6.4.10 singularity

Procedure from library `classify.lib` (see [Section D.6.4 \[classify.lib\], page 1650](#)).

Usage: `singularity(t, l);` `t=string` (name of singularity),
 `l=list` of integers/polynomials (indices/parameters of singularity)

Compute: get the singularity named by type `t` from the database. list `l` is as follows:
 `l= k [r [s [a [b [c [d]..]:` `k,r,s=int` `a,b,c,d=poly`.
 The name of the dbm-databasefile is: `NFlist.[dir,pag]`. The file is found in the current directory. If it does not exist, please run the script `MakeDBM` first.

Return: Normal form and corank of the singularity named by type `t` and its index (indices) `l`.

Example:

```
LIB "classify.lib";
ring r=0,(x,y,z),(c,ds);
init_debug(0);
singularity("E[6k]",6);
↪ [1]:
↪   x3+xy13+y19
↪ [2]:
↪   2
singularity("T[k,r,s]", 3, 7, 5);
↪ [1]:
↪   x3+xyz+z5+y7
↪ [2]:
↪   3
poly f=y;
singularity("J[k,r]", 4, 0, 0, f);
↪ [1]:
↪   x3+x2y4+y13
↪ [2]:
↪   2
```

D.6.4.11 A_L

Procedure from library `classify.lib` (see [Section D.6.4 \[classify.lib\], page 1650](#)).

Usage: `A_L(f);` `f poly`
 `A_L(s);` `s string`, the name of the singularity

Compute: the normal form of `f` in Arnold's list of singularities in case 1, in case 2 nothing has to be computed.

Return: `A_L(f)`: compute via 'milnorcode' the class of `f` and return the normal form of `f` found in the database.
 `A_L("name")`: get the normal form from the database for the singularity given by its name.

Example:

```
LIB "classify.lib";
ring r=0,(a,b,c),ds;
poly f=A_L("E[13]");
f;
↪ c2+a3+ab5+b8
```

```

A_L(f);
↳ Singularity R-equivalent to : E[6k+1]=E[13]
↳ normal form : c2+a3+ab5+b8
↳ c2+a3+ab5+b8

```

D.6.4.12 normalform

Procedure from library `classify.lib` (see [Section D.6.4 \[classify.lib\], page 1650](#)).

Usage: `normalform(s); s=string`

Return: Arnold's normal form of singularity with name `s`

Example:

```

LIB "classify.lib";
ring r=0,(a,b,c),ds;
normalform("E[13]");
↳ c2+a3+ab5+b8

```

D.6.4.13 debug_log

Procedure from library `classify.lib` (see [Section D.6.4 \[classify.lib\], page 1650](#)).

Usage: `debug_log(level,li); level=int, li=comma separated "message" list`

Compute: `print "messages" if level>=@DeBug.`
 useful for user-defined trace messages.

Example:

```

LIB "classify.lib";
example init_debug;
↳ // proc init_debug from lib classify.lib
↳ EXAMPLE:
↳   init_debug();
↳   debug_log(1,"no trace information printed");
↳   init_debug(1);
↳ Debugging level change from 0 to 1
↳   debug_log(1,"some trace information");
↳ some trace information
↳   init_debug(2);
↳ Debugging level change from 1 to 2
↳   debug_log(2,"nice for debugging scripts");
↳ Debug:(2): nice for debugging scripts
↳   init_debug(0);
↳ Debugging switched off.
↳

```

See also: [Section D.6.4.5 \[init_debug\], page 1653](#).

D.6.4.14 swap

Procedure from library `classify.lib` (see [Section D.6.4 \[classify.lib\], page 1650](#)).

Usage: `swap(a,b);`

Return: `b,a` if `a,b` is the input (any type)

Example:

```
LIB "classify.lib";
swap("variable1","variable2");
⇨ variable2 variable1
```

D.6.4.15 modality

Procedure from library `classify.lib` (see [Section D.6.4 \[classify_lib\], page 1650](#)).

Usage: `modality(f); f poly`

Return: the modality of the singularity

Example:

```
LIB "classify.lib";
ring r = 0, (x,y,z), ds;
poly f = (x2+3y-2z)^2+xyz-(x-y3+x2z3)^3;
modality(f);
⇨ 0
```

D.6.4.16 complexSingType

Procedure from library `classify.lib` (see [Section D.6.4 \[classify_lib\], page 1650](#)).

Usage: `complexSingType(f); f poly`

Return: the type of the singularity as a string

Example:

```
LIB "classify.lib";
ring r = 0, (x,y,z), ds;
poly f = (x2+3y-2z)^2+xyz-(x-y3+x2z3)^3;
complexSingType(f);
⇨ D[4]
```

D.6.4.17 prepRealclassify

Procedure from library `classify.lib` (see [Section D.6.4 \[classify_lib\], page 1650](#)).

Usage: `prepRealclassify(f); f poly`

Return: a list, containing the modality of the singularity and the type of the singularity as a string
This procedure is needed in `realclassify.lib` in order to avoid `classify()` being called more than once.

Example:

```
LIB "classify.lib";
ring r = 0, (x,y,z), ds;
poly f = (x2+3y-2z)^2+xyz-(x-y3+x2z3)^3;
prepRealclassify(f);
⇨ [1]:
⇨ 0
⇨ [2]:
⇨ D[4]
```

D.6.5 `classify2_lib`

Library: `classify2.lib`

Purpose: Classification of isolated singularities

Authors: Janko Boehm, email: boehm@mathematik.uni-kl.de
 Magdaleen Marais, email: magdaleen.marais@up.ac.za
 Gerhard Pfister, email: pfister@mathematik.uni-kl.de

Overview: We classify isolated singularities of corank ≤ 2 and modality ≤ 2 with respect to right-equivalence over the complex numbers according to Arnold's list. We determine the type and, for positive modality, the parameter.

V.I. Arnold has described normal forms and has developed a classifier for, in particular, all isolated hypersurface singularities over the complex numbers up to modality 2. Building on a series of 105 theorems, this classifier determines the type of the given singularity. However, for positive modality, this does not fix the right equivalence class of the singularity, since the values of the moduli parameters are not specified.

This library implements an alternative classification algorithm for isolated hypersurface singularities of corank and modality up to two. For a singularity given by a polynomial over the rationals, the algorithm determines its right equivalence class by specifying a polynomial representative in Arnold's list of normal forms. In particular, the algorithm also determines values for the moduli parameters.

The implementation is based on the paper

Janko Boehm, Magdaleen Marais, Gerhard Pfister: A Classification Algorithm for Complex Singularities of Corank and Modality up to Two, *Singularities and Computer Algebra - Festschrift for Gert-Martin Greuel on the Occasion of his 70th Birthday*, Springer 2017, <http://arxiv.org/abs/1604.04774>, https://doi.org/10.1007/978-3-319-28829-1_2

There are functions for determining a normal form equation and for determining the complex type of the singularity.

Procedures: See also: [Section D.6.4 \[`classify_lib`\], page 1650](#); [Section D.6.19 \[`realclassify_lib`\], page 1750](#).

D.6.5.1 `complexClassify`

Procedure from library `classify2.lib` (see [Section D.6.5 \[`classify2_lib`\], page 1659](#)).

Usage: `complexClassify(f1); f1 Poly`

Assume: `f1` is a bivariate polynomial defining a curve singularity at $(0,0)$ of modality ≤ 2 and corank ≤ 2 . The ordering of the basering must be local.

Return: A normal form equation `g` for `f1` represented by an element of type `NormalFormEquation`.

Note: So far the final scaling step is not implemented, so to obtain a normal form equation it may be necessary to do a transformation of the form $x \rightarrow \lambda_1 x$, $y \rightarrow \lambda_2 y$

Note: Case X9 is not implemented yet. In this case an error is returned stating that it is case X9.

`g.normalFormEquation.in` stores the polynomial ring containing the normal form equation.

`g.normalFormEquation.value` is the normal form equation.

To access the normal form equation as a polynomial do:

```
def S = g.normalFormEquation.in;
setring S;
poly nf = g.normalFormEquation.value;
```

Example:

```
LIB "classify2.lib";
ring R = 0,(x,y),ds;
Poly f = -16065*y^9*x-5103*y^9-128*x^7-595*y^9*x^4+6*y^5-21*y^9*x^5-2187*y^7+4*x^2*y^9;
NormalFormEquation F = complexClassify(f);
F;
↳ Corank = 2
↳ Normalform equation of type = Y[7,8]
↳ Normalform equation = x2y2-x7+y8
↳ Milnor number = 16
↳ Modality = 1
↳ Parameter term = x2y2
↳ Determinacy <= 8
↳
def S = F.normalFormEquation.in;
setring S;
poly nf = F.normalFormEquation.value;
```

D.6.5.2 complexType

Procedure from library `classify2.lib` (see [Section D.6.5 \[classify2.lib\]](#), page 1659).

Usage: `complexType(f); fl Poly`

Assume: `fl` is a bivariate polynomial defining a curve singularity at (0,0) of modality and corank ≤ 2 . The ordering of the basering must be local.

Return: A list with the complex type of `fl` and the modality.

Example:

```
LIB "classify2.lib";
ring R = 0,(x,y),ds;
Poly f = -16065*y^9*x-5103*y^9-128*x^7-595*y^9*x^4+6*y^5-21*y^9*x^5-2187*y^7+4*x^2*y^9;
complexType(f);
```

```

↦ [1] :
↦      Y[7,8]
↦ [2] :
↦      1

```

D.6.6 classify_aeq_lib

Library: classifyAeq.lib

Purpose: Simple Space Curve singularities in characteristic 0

Authors: Faira Kanwal Janjua fairakanwaljanjua@gmail.com
 Gerhard Pfister pfister@mathematik.uni-kl.de Khawar Mehmood
 khawar1073@gmail.com

Overview: A library for classifying the simple singularities with respect to A equivalence in characteristic 0. Simple Surface singularities in characteristic 0 have been classified by Bruce and Gaffney [4] resp. Gibson and Hobbs [1] with respect to A equivalence. If the input is one of the simple singularities in [1] it returns a normal form otherwise a zero ideal (i.e not simple).

Procedures:

D.6.6.1 sagbiAlg

Procedure from library `classify_aeq.lib` (see [Section D.6.6 \[classify_aeq.lib\]](#), page 1661).

Return: An ideal. The sagbi bases of I.

Example:

```

LIB "classify_aeq.lib";
ring R=0,t,ds;
ideal I=t8,t10+t13,t12+t15;
sagbiAlg(I);
↦ _[1]=t8
↦ _[2]=t10+t13
↦ _[3]=t12+t15
↦ _[4]=t23-t29
↦ _[5]=t27
I=t8,t10+t13,t12+2t15;
sagbiAlg(I);
↦ _[1]=t8

```

```

⇒ _[2]=t10+t13
⇒ _[3]=t12+2t15
⇒ _[4]=t27-3t33
⇒ _[5]=t29

```

D.6.6.2 sagbiMod

Procedure from library `classify_aeq.lib` (see [Section D.6.6 \[classify_aeq.lib\]](#), page 1661).

Return: An ideal. the sagbi bases for the differential module.

Example:

```

LIB "classify_aeq.lib";
ring r=0,t,Ds;
ideal G=t8,t10+t13,t12+t15,t23-t29,t27;
ideal I=diff(G,t);
sagbiMod(I,G);
⇒ _[1]=t7
⇒ _[2]=t9+13/10t12
⇒ _[3]=t11+5/4t14
⇒ _[4]=t20
⇒ _[5]=t22-29/23t28
⇒ _[6]=t24
⇒ _[7]=t26
⇒ _[8]=t28

```

D.6.6.3 semiGroup

Procedure from library `classify_aeq.lib` (see [Section D.6.6 \[classify_aeq.lib\]](#), page 1661).

Return: list L; list with three entries associated to the algebra generated by the sagbi basis:
 generators of the semigroup
 the conductor
 the semigroup

Example:

```

LIB "classify_aeq.lib";
ring R=0,t,ds;
ideal I=t8,t10+t13,t12+t15,t23-t29,t27;
semiGroup(I);
⇒ [1]:
⇒ 8,10,12,23,27
⇒ [2]:
⇒ 30
⇒ [3]:
⇒ 0,8,10,12,16,18,20,22,23,24,26,27,28,30
I=t8,t10+t13,t12+2t15,t27-3t33,t29;
semiGroup(I);
⇒ [1]:
⇒ 8,10,12,27,29
⇒ [2]:
⇒ 34
⇒ [3]:
⇒ 0,8,10,12,16,18,20,22,24,26,27,28,29,30,32,34

```

D.6.6.4 semiMod

Procedure from library `classify_aeq.lib` (see [Section D.6.6 \[classify_aeq.lib\], page 1661](#)).

Return: list K;
 K[1]min generators of the semialgebra.
 K[2]conductor of the algebra.
 K[3]generators for the semialgebra.
 K[4]min generators of the module.
 K[5]conductor of the module.
 K[6]semigroup of the module.

Example:

```
LIB "classify_aeq.lib";
ring r=0,t,Ds;
ideal G=t4,t7+t10;
ideal I=diff(G,t);
ideal k=sagbiMod(I,G);
semiMod(k,G);
⇒ [1]:
⇒ 4,7
⇒ [2]:
⇒ 18
⇒ [3]:
⇒ 0,4,7,8,11,12,14,15,16,18
⇒ [4]:
⇒ 3,6,16
⇒ [5]:
⇒ 13
⇒ [6]:
⇒ 3,6,7,10,11,13
```

D.6.6.5 planeCur

Procedure from library `classify_aeq.lib` (see [Section D.6.6 \[classify_aeq.lib\], page 1661](#)).

Return: An ideal. Ideal is one of the singularity in the list of Bruce and Gaffney [4]

Example:

```
LIB "classify_aeq.lib";
ring R=0,t,Ds;
ideal I=t4+4t5+6t6+8t7+13t8+12t9+10t10+12t11+6t12+4t13+4t14+t16,t7+7t8+22t9+51t10+11t11+1828t18+2011t19+2165t20+2163t21+1982t22+1806t23+1491t24+1141t25+889t26+588t27+379t28;
planeCur(I);
⇒ // ** redefining K (intvec q=4,7;list K;) classify_aeq.lib\
b::planeCur:155
⇒ _[1]=t4
⇒ _[2]=t7+t9
```

D.6.6.6 spaceCur

Procedure from library `classify_aeq.lib` (see [Section D.6.6 \[classify_aeq.lib\], page 1661](#)).

Return: an ideal. Ideal is one of the singularity in the list of C.G.Gibson and C.A.Hobbs.

Example:

```

LIB "classify_aeq.lib";
ring R=0,t,Ds;
ideal I=t3+3t4+3t5+t6,t13+14t14+92t15+377t16+1079t17+2288t18+3718t19+4719t20+4719t21;
spaceCur(I);
↪ _[1]=t3
↪ _[2]=t13+t14
↪ _[3]=t17

```

D.6.6.7 HHnormalForm

Procedure from library `classify_aeq.lib` (see [Section D.6.6 \[classify_aeq.lib\]](#), page 1661).

Usage: `HHnormalForm(I)`, $I=\langle x(t), y(t) \rangle$ an ideal, `#` optional, a bound for the conductor

Compute: computes the Hefez-Hernandez normal form of the ideal $I=\langle x(t), y(t) \rangle$

Return: a list `L` with 5 entries

`L[1]` the Hefei-Hernandez normal form of the ideal $I=\langle x(t), y(t) \rangle$ `L[2]` the semi group Γ
`L[3]` the semi module Λ
`L[4]` 0 if $\Lambda=\Gamma$ or $\lambda=\min(\Lambda-\Gamma)$ -n, the Zariski number
`L[5]` the integers i , $i>\lambda$, $i+n$ not in Λ , 0 if this set is empty

Example:

```

LIB "classify_aeq.lib";
ring r=0,t,Ds;
ideal I=t6+3t7,t8+t13+t19;
HHnormalForm(I);
↪ [1]:
↪   _[1]=t6
↪   _[2]=t8-4t9+425/6t11-823/32t13
↪ [2]:
↪   0,6,8,12,14,16,18,20,22,24,25,26,28,30,31,32,33,34,36
↪ [3]:
↪   0,6,8,12,14,15,16,18,20
↪ [4]:
↪   9
↪ [5]:
↪   11,13

```

D.6.6.8 modSagbiAlg

Procedure from library `classify_aeq.lib` (see [Section D.6.6 \[classify_aeq.lib\]](#), page 1661).

Usage: `modSagbiAlg(I,i)`; I is an ideal, i an integer (optional).

Return: ideal, a sagbi basis for I using modular methods.

Purpose: Computes a sagbi basis for the ideal given by the generators in I using modular techniques.
 If second argument is 0 then the result is not verified.

Example:

```

LIB "classify_aeq.lib";
ring R=0,t,ds;
ideal I=t8,t10+t13,t12+t15;

```

```

modSagbiAlg(I,0);
↪ _[1]=t8
↪ _[2]=t10+t13
↪ _[3]=t12+t15
↪ _[4]=t23-t29
↪ _[5]=t27
modSagbiAlg(I);
↪ _[1]=t8
↪ _[2]=t10+t13
↪ _[3]=t12+t15
↪ _[4]=t23-t29
↪ _[5]=t27

```

D.6.6.9 classSpaceCurve

Procedure from library `classify_aeq.lib` (see [Section D.6.6 \[classify_aeq.lib\]](#), page 1661).

Return: the normal form of I if I is simple, -1 if I is not simple

Example:

```

LIB "classify_aeq.lib";
ring R=31,t,ds;
ideal I=t3+6t4+13t5-13t6+10t7+2t8-6t9-10t10-15t11-6t12+8t13-2t14+t15+8t16,
t7+15t8+7t9-11t10-15t11-6t12+8t13-2t14+t15+8t16,
t10-11t11-6t12-t13+12t14+4t15-14t16+15t17-12t18+5t19+t20;
ideal J=classSpaceCurve(I);
J;
↪ J[1]=t3
↪ J[2]=t7+t8
↪ J[3]=t11

```

D.6.7 classifyceq.lib

Library: `classifyCeq.lib`

Purpose: simple hypersurface singularities in characteristic $p > 0$

Authors: Deeba Afzal deebafzal@gmail.com
 Faira Kanwal Janjua fairakanwaljanjua@gmail.com

Overview: A library for classifying the simple singularities with respect to contact equivalence in characteristic $p > 0$. Simple hypersurface singularities in characteristic $p > 0$ were classified by Greuel and Kroening [1] with respect to contact equivalence. The classifier we use has been proposed in [2].

References:

- [2] Afzal,D.;Binyamin,M.A.;Janjua,F.K.: On the classification of simple singularities in positive characteristic.

Procedures:

D.6.7.1 classifyCeq

Procedure from library `classifyceq.lib` (see [Section D.6.7 \[classifyceq.lib\]](#), page 1665).

Usage: `classifyCeq(f); f poly`

Return: string including the Tjurina number of f and its type in the classification of Greuel and Kroening

Example:

```
LIB "classifyceq.lib";
ring R=3,(x,y,z,u,v,w),ds;
classifyCeq(-x2+xy+y2+xz-yz-z2+w2+u3+v4);
⇒ The given function defines a simple singularity.
⇒ The tjurina number is 9.
⇒ E^0[6]:x^3+y^4
```

D.6.8 classifyci.lib

Library: `classifyci.lib`

Purpose: Isolated complete intersection singularities in characteristic 0

Authors: Gerhard Pfister pfister@mathematik.uni-kl.de
Deeba Afzal deebafzal@gmail.com

Overview: A library for classifying isolated complete intersection singularities for the base field of characteristic 0 and for computing weierstrass semigroup of the space curve. Isolated complete intersection singularities were classified by M. Giusti [1] for the base field of characteristic 0. Algorithm for the semigroup of a space curve singularity is given in [2].

References:

- [1] Giusti, M: Classification des singularities isolees simples d'intersections completes, C.R. Acad. Sci. Paris Ser. A-B 284(1977), 167-169.
- [2] Castellanos, A., Castellanos, J., 2005: Algorithm for the semigroup of a space curve singularity. Semigroup Forum 70, 44-66.

Procedures:

D.6.8.1 classifyicis

Procedure from library `classifyci.lib` (see [Section D.6.8 \[classifyci.lib\]](#), page 1666).

Usage: `classifyicis(I); I ideal`

Assume: I is given by two generators

Purpose: Check whether the ideal defines a complete intersection singularity or not

Return: String type in the classification of Giusti, M
or The given singularity is not simple

Example:

```
LIB "classifyci.lib";
ring R=0,(x,y,z),ds;
ideal I=x2+yz,xy+z4;
classifyicis(I);
```

```

⇒ // ** dim(_) may be wrong because the mixed monomial ordering
⇒ // ** dim(_) may be wrong because the mixed monomial ordering
⇒ // ** dim(I) may be wrong because the mixed monomial ordering
⇒ // ** dim(I) may be wrong because the mixed monomial ordering
⇒ U_9: (x2+yz,xy+z4)

```

D.6.8.2 Semigroup

Procedure from library `classifysi.lib` (see [Section D.6.8 \[classifysi.lib\]](#), page 1666).

Usage: `Semigroup(I)`; I is an ideal

Purpose: Computes the semigroup of the ideal I corresponding to each branch

Return: list of semigroup of ideal I corresponding to each branch

Example:

```

LIB "classifysi.lib";
ring R=0,(x,y,z),ds;
ideal I=x2+y3+z5,yz;
Semigroup(I);
⇒ [1]:
⇒    2,3
⇒ [2]:
⇒    2,5

```

D.6.9 classifyMapGerms.lib

Library: `classifyMapGerms.lib`

Authors: Gerhard Pfister, pfister@mathematik.uni-kl.de
 Deeba Afzal, deebafzal@gmail.com
 Shamsa Kanwal, lotus_zone16@yahoo.com

Overview: A library for computing the standard basis of the tangent space at the orbit of an algebraic group action. The tangent space is usually described as the sum of two modules over different rings. It computes the standard basis using modular methods and parallel modular methods. It also computes the normal form of the germ given by Riegers classification.

Procedures:

D.6.9.1 coDimMap

Procedure from library `classifyMapGerms.lib` (see [Section D.6.9 \[classifyMapGerms.lib\]](#), page 1667).

Usage: `coDimMap(I, #);` I =ideal, $\#$ =list

Compute: a bound of the A-determinacy of the map germ defined by I .

Return: a list in which 1st entry gives the bound of the A-determinacy and the second entry gives the codimension of the map germ defined by I .

Note: if $\#$ is empty it computes A^e -codimension(the extended codimension).

Example:

```
LIB "classifyMapGerms.lib";
ring R=0,(x,y),(c,ds);
poly f1=x;
poly f2=xy+y5+y7;
poly f11=f1+f2*f1;
poly f22=f2+f1^2;
map phi=basing,x+y,y+y2;
f1=phi(f11);
f2=phi(f22);
ideal I=f1,f2;
coDimMap(I);
↳ [1]:
↳ 14
↳ [2]:
↳ 2
coDimMap(I,1);
↳ [1]:
↳ 15
↳ [2]:
↳ 4
```

D.6.9.2 coDim

Procedure from library `classifyMapGerms.lib` (see [Section D.6.9 \[classifyMapGerms.lib\]](#), [page 1667](#)).

Usage: `coDim(module M, module N, ideal I,int bound, list #);` M is a submodule in A^r over the basering $=:A$, N is a submodule in R^r over the subring R of the basering generated by the entries of I

Compute: computes the K -vectorspace dimension of $A^r/M+N+\maxideal(bound)*A^r$

Return: an integer

Note: if $\#$ is not empty the bound is corrected by computing determinacy

Example:

```
LIB "classifyMapGerms.lib";
ring R=0,(x,y),(c,ds);
poly f1=x;
poly f2=xy+y5+y7;
poly f11=f1+f2*f1;
poly f22=f2+f1^2;
map phi=basing,x+y,y+y2;
f1=phi(f11);
f2=phi(f22);
ideal I=f1,f2;
```

```

module M=maxideal(1)*jacob(I);
module N=I*freemodule(2);
coDim(M,N,I,15);
↦ 6

```

D.6.9.3 vStd

Procedure from library `classifyMapGerms.lib` (see [Section D.6.9 \[classifyMapGerms.lib\]](#), [page 1667](#)).

Usage: `vStd(M, N, I, bound)`; M is a submodule in A^r over the basering $=:A$, N is a submodule in R^r over the subring R of the basering generated by the entries of I

Compute: a standard basis of $M+N+\maxideal(bound)*A^r$

Return: a list whose i th entry gives a list where each entry is a generator of standard basis and second entry gives a list of generators after the reduced echelon form

Example:

```

LIB "classifyMapGerms.lib";
ring R=0,(x,y),(c,ds);
poly f1=x;
poly f2=xy+y5+y7;
poly f11=f1+f2*f1;
poly f22=f2+f1^2;
map phi=basing,x+y,y+y2;
f1=phi(f11);
f2=phi(f22);
ideal I=f1,f2;
module M=maxideal(1)*jacob(I);
module N=I*freemodule(2);
vStd(M,N,I,15);

D.6.9.4 modVStd

Procedure from library `classifyMapGerms.lib` (see [Section D.6.9 \[classifyMapGerms.lib\]](#), [page 1667](#)).

Usage: `modVStd((M, N, I, bound, #); M is a submodule
in A^r over the basering A , N is a submodule in R^r over the subring R of the
basing generated by the entries of I`

Compute: a standard basis of $A^r/M+N+\text{maxideal}(\text{bound})*A^r$ using modular version

Return: a list whose `ist` entry gives a list where each entry is a generator of standard basis and second entry gives a list of generators after the reduced echelon form

Note: if `#` is not empty the bound is corrected by computing determinacy

Example:

```
LIB "classifyMapGerms.lib";
ring R=0,(x,y),(c,ds);
poly f1=x;
poly f2=xy+y5+y7;
poly f11=f1+f2*f1;
poly f22=f2+f1^2;
map phi=basing,x+y,y+y2;
f1=phi(f11);
f2=phi(f22);
ideal I=f1,f2;
module M=maxideal(1)*jacob(I);
module N=I*freemodule(2);
modVStd(M,N,I,15);

D.6.9.5 modVStd0

Procedure from library `classifyMapGerms.lib` (see [Section D.6.9 \[classifyMapGerms.lib\]](#), [page 1667](#)).

Usage: `modVStd0((M, N, I, bound, #));` M is a submodule in A^r over the basering $=:A$, N is a submodule in R^r over the subring R of the basering generated by the entries of I

Compute: a standard basis of $M+N+\text{maxideal}(\text{bound})*A^r$ using the parallel modular version

Return: a list whose i th entry gives a list where each entry is a generator of standard basis and second entry gives a list of generators after the reduced echelon form

Note: if $\#$ is not empty the bound is corrected by computing determinacy

Example:

```
LIB "classifyMapGerms.lib";
ring R=0,(x,y),(c,ds);
poly f1=x;
poly f2=xy+y5+y7;
poly f11=f1+f2*f1;
poly f22=f2+f1^2;
map phi=basing,x+y,y+y2;
f1=phi(f11);
f2=phi(f22);
ideal I=f1,f2;
module M=maxideal(1)*jacob(I);
module N=I*freemodule(2);
modVStd0(M,N,I,15);

D.6.9.6 classifySimpleMaps

Procedure from library `classifyMapGerms.lib` (see [Section D.6.9 \[classifyMapGerms.lib\]](#), [page 1667](#)).

Usage: `classifySimpleMaps(I)`; I=an ideal with 2 generators in a polynomial ring with 2 variables and local ordering defining a map germ C^2 to C^2

Compute: The normal form of the germ in Riegers classification if it is simple

Return: normal form of I, of type ideal

Note: If I is not simple it returns (0,0)

Example:

```

LIB "classifyMapGerms.lib";
ring R=0,(x,y),(c,ds);
poly f1=x;
poly f2=xy+y5+y7;
poly f11=f1+f2*f1;
poly f22=f2+f1^2;
map phi=basing,x+y,y+y2;
f1=phi(f11);
f2=phi(f22);
ideal I=f1,f2;
classifySimpleMaps(I);
↪ _[1]=x
↪ _[2]=xy+y5+y7

```

D.6.9.7 classifySimpleMaps1

Procedure from library `classifyMapGerms.lib` (see [Section D.6.9 \[classifyMapGerms.lib\]](#), [page 1667](#)).

Usage: `classifySimpleMaps1(I)`; I=an ideal with 2 generators in a polynomial ring with 2 variables and local ordering defining a map germ C^2 to C^2

Compute: The normal form of the germ in Riegers classification if it is simple

Return: normal form of I, of type ideal

Note: If I is not simple it returns (0,0)

Example:

```

LIB "classifyMapGerms.lib";
ring R=0,(x,y),(c,ds);
poly f1=x;
poly f2=xy+y5+y7;
poly f11=f1+f2*f1;
poly f22=f2+f1^2;
map phi=basing,x+y,y+y2;
f1=phi(f11);

```

```

f2=phi(f22);
ideal I=f1,f2;
classifySimpleMaps1(I);
↦ _[1]=x
↦ _[2]=xy+y5+y7

```

D.6.9.8 classifyUnimodalMaps

Procedure from library `classifyMapGerms.lib` (see [Section D.6.9 \[classifyMapGerms.lib\]](#), [page 1667](#)).

Usage: `classifyUnimodalMaps(I)`; I an ideal with 2 generators in a polynomial ring with 2 variables and local ordering defining a map germ C^2 to C^2

Compute: The normal form of the germ in Riegers classification if it is simple

Return: normal form of I, of type ideal

Note: If I is not unimodal it returns (0,0)

Example:

```

LIB "classifyMapGerms.lib";
ring R=0,(x,y),(c,ds);
poly f1=x;
poly f2=xy+y6+y9;
poly f11=f1+f2*f1;
poly f22=f2+f1^2;
map phi=basing,x+y,y+y2;
f1=phi(f11);
f2=phi(f22);
ideal I=f1,f2;
classifyUnimodalMaps(I);
↦ _[1]=x
↦ _[2]=xy+y6+y9

```

D.6.10 curvepar.lib

Library: `curvepar.lib`

Purpose: Resolution of space curve singularities, semi-group

Author: Gerhard Pfister email: pfister@mathematik.uni-kl.de Nil Sahin email: e150916@metu.edu.tr
Maryna Viazovska email: viazovsk@mathematik.uni-kl.de

Procedures: See also: [Section D.6.21 \[spcurve.lib\]](#), [page 1772](#).

D.6.10.1 BlowingUp

Procedure from library `curvepar.lib` (see [Section D.6.10 \[curvepar.lib\]](#), [page 1686](#)).

Usage: `BlowingUp(f,I,l)`;
f=poly
b=ideal
l=list

Assume: The basering is $r=0, (x(1..n), a), dp$
 f is an irreducible polynomial in $k[a]$,
 I is an ideal of a curve (if we consider a as a parameter)

Compute: Blowing-up of the curve at point 0.

Return: list C of charts.
Each chart $C[i]$ is a list of size 5 (reps. 6 in case of plane curves) $C[i][1]$ is an integer j .
It shows, which standard chart do we consider. $C[i][2]$ is an irreducible poly g in $k[a]$.
It is a minimal polynomial for the new parameter.
 $C[i][3]$ is an ideal H in $k[a]$.
 $c_i = F_i(a_{new})$ for $i=1..n$,
 $a_{old} = H[n+1](a_{new})$.
 $C[i][4]$ is a map $teta: k[x(1)..x(n), a] \rightarrow k[x(1)..x(n), a]$ from the new curve to the old one.
 $x(1) \rightarrow x(j) * x(1) \dots x(j) \rightarrow x(j) \dots x(n) \rightarrow x(j) * (c_{n+1} + x(n))$
 $C[i][5]$ is an ideal J of a new curve. $J = teta(I)$.
 $C[i][6]$ is the list of exceptional divisors in the chart

Example:

```
LIB "curvepar.lib";
ring r=0, (x(1..3), a), dp;
poly f=a^2+1;
ideal i=x(1)^2+a*x(2)^3, x(3)^2-x(2);
list l=1,3,2;
list B=BlowingUp(f,i,l);
B;
⇒ [1]:
⇒ [1]:
⇒ 3
⇒ [2]:
⇒ a^2+1
⇒ [3]:
⇒ _[1]=0
⇒ _[2]=0
⇒ _[3]=1
⇒ [4]:
⇒ _[1]=x(1)*x(3)
⇒ _[2]=x(2)*x(3)
⇒ _[3]=x(3)
⇒ _[4]=a
⇒ [5]:
⇒ _[1]=x(2)-x(3)
⇒ _[2]=x(2)^3*x(3)*a+x(1)^2
```

D.6.10.2 CurveRes

Procedure from library `curvepar.lib` (see [Section D.6.10 \[curvepar.lib\]](#), page 1686).

Usage: CurveRes(I);
 I ideal

Assume: The basering is $r=0, (x(1..n))$
 $V(I)$ is a curve with a singular point 0.

Compute: Resolution of the curve $V(I)$.

Return: a ring $R = \text{basering} + k[a]$
 Ring R contains a list `Resolve`
`Resolve` is a list of charts
 Each `Resolve[i]` is a list of size 6
`Resolve[i][1]` is an ideal J of a new curve. $J = \text{teta}(I)$. `Resolve[i][2]` ideal which represents the map
 $\text{teta}: k[x(1)..x(n), a] \rightarrow k[x(1)..x(n), a]$ from the new curve to the old one.
`Resolve[i][3]` is an irreducible poly g in $k[a]$. It is a minimal polynomial for the new parameter a . $\deg(g)$ gives the number of branches in `Resolve[i]` `Resolve[i][4]` sequence of multiplicities (sum over all branches in `Resolve` as long as they intersect each other !)
`Resolve[i][5]` is a list of integers l . It shows, which standard charts we considered.
`Resolve[i][6]` HN matrix
`Resolve[i][7]` (only for plane curves) the development of exceptional divisors the entries correspond to the i -th blowing up. The first entry is an intvec. The first negative entry gives the splitting of the (over \mathbb{Q} irreducible) branches. The second entry is a list of the exceptional divisors. If the entry is an integer i , it says that the divisor is not visible in this chart after the i -th blowing up.

Example:

```
LIB "curvepar.lib";
ring r=0,(x,y,z),dp;
ideal i=x2-y3,z2-y5;
def s=CurveRes(i);
setring s;
Resolve;

⇒      _[3]=0
⇒      [4]:
⇒      _[1]=0
⇒      _[2]=1
⇒      _[3]=1

```

D.6.10.3 CurveParam

Procedure from library `curvepar.lib` (see [Section D.6.10 \[curvepar.lib\]](#), page 1686).

Usage: CurveParam(I);
 I ideal

Assume: I is an ideal of a curve C with a singular point 0.

Compute: Parametrization for algebraic branches of the curve C.

Return: list L of size 1.
 L[1] is a ring ring rt=0,(t,a),ds;
 Ring R contains a list Param
 Param is a list of algebraic branches
 Each Param[i] is a list of size 3
 Param[i][1] is a list of polynomials
 Param[i][2] is an irreducible polynomial $f \in k[a]$. It is a minimal polynomial for the
 parameter a.
 Param[i][3] is an integer b-upper bound for the conductor of Weierstrass semigroup

Example:

```

LIB "curvepar.lib";
ring r=0,(x,y,z),dp;
ideal i=x2-y3,z2-y5;
def s=CurveParam(i);
setring s;
Param;
⇒ [1]:
⇒      [1]:
⇒      t3
⇒      [2]:
⇒      t2
⇒      [3]:
⇒      -t5
⇒      [2]:
⇒      a

```

```

⇒      [3]:
⇒      38
⇒ [2]:
⇒      [1]:
⇒      [1]:
⇒      t3
⇒      [2]:
⇒      t2
⇒      [3]:
⇒      t5
⇒      [2]:
⇒      a
⇒      [3]:
⇒      38

```

D.6.10.4 WSemigroup

Procedure from library `curvepar.lib` (see [Section D.6.10 \[curvepar.lib\]](#), page 1686).

Usage: `WSemigroup(X,b0);`
 `X` a list of polynomials in one variable, say `t`.
 `b0` an integer

Compute: Weierstrass semigroup of space curve `C`, which is given by a parametrization `X[1](t),...,X[k](t)`, till the bound `b0`.

Assume: `b0` is greater then conductor

Return: list `M` of size 5.
 `M[1]`= list of integers, which are minimal generators set of the Weierstrass semigroup.
 `M[2]`=integer, conductor of the Weierstrass semigroup. `M[3]`=intvec, all elements of the Weierstrass semigroup till some bound `b`, which is greater than conductor.

Warning: works only over the ring with one variable with ordering `ds`

Example:

```

LIB "curvepar.lib";
ring r=0,(t),ds;
list X=t4,t5+t11,t9+2*t7;
list L=WSemigroup(X,30);
L;
⇒ [1]:
⇒ 4,5,7
⇒ [2]:
⇒ 7
⇒ [3]:
⇒ 4,5,7,8,9,10

```

D.6.10.5 primparam

Procedure from library `curvepar.lib` (see [Section D.6.10 \[curvepar.lib\]](#), page 1686).

Usage: `MultiplicitySequence(x,y,c);` `x` poly, `y` poly, `c` integer

Assume: `x` and `y` are polynomials in $k(a)[t]$ such that (x,y) is a primitive parametrization of a plane curve branch and $\text{ord}(x) < \text{ord}(y)$.

Return: Hamburger-Noether Matrix of the curve branch given parametrically by (x,y) .

Example:

```
LIB "curvepar.lib";
ring r=(0,a),t,ds;
poly x=t6;
poly y=t8+t11;
int c=15;
primparam(x,y,c);
↪ _[1,1]=0

```

$\mapsto _ [3,15]=0$

D.6.10.6 MultiplicitySequence

Procedure from library `curvepar.lib` (see [Section D.6.10 \[curvepar.lib\]](#), page 1686).

Usage: `MultiplicitySequence(i); i ideal`

Assume: `i` is the defining ideal of a (reducible) plane curve singularity.

Return: list `X` of charts. Each chart contains the multiplicity sequence of the corresponding branch.

Example:

```
LIB "curvepar.lib";
ring r=0,(x,y),ds;
ideal i=x14-x4y7-y11;
MultiplicitySequence(i);
 $\mapsto$  [1]:
 $\mapsto$  1
 $\mapsto$  [2]:
 $\mapsto$  1
 $\mapsto$  [3]:
 $\mapsto$  1
 $\mapsto$  [4]:
 $\mapsto$  1
 $\mapsto$  [5]:
 $\mapsto$  7,3,3,1,1,1
```

D.6.10.7 CharacteristicExponents

Procedure from library `curvepar.lib` (see [Section D.6.10 \[curvepar.lib\]](#), page 1686).

Usage: `CharacteristicExponents(i); i ideal`

Assume: `i` is the defining ideal of a (reducible) plane curve singularity.

Return: list `X` of charts. Each chart contains the characteristic exponents of the corresponding branch.

Example:

```
LIB "curvepar.lib";
ring r=0,(x,y),ds;
ideal i=x14-x4y7-y11;
CharacteristicExponents(i);
 $\mapsto$  [1]:
 $\mapsto$  1
 $\mapsto$  [2]:
 $\mapsto$  1
 $\mapsto$  [3]:
 $\mapsto$  1
 $\mapsto$  [4]:
 $\mapsto$  1
 $\mapsto$  [5]:
 $\mapsto$  7,10
```

D.6.10.8 IntersectionMatrix

Procedure from library `curvepar.lib` (see [Section D.6.10 \[curvepar.lib\]](#), page 1686).

Usage: `IntersectionMatrix(i)`; i ideal

Assume: i is the defining ideal of a (reducible) plane curve singularity.

Return: intmat of the intersection multiplicities of the branches.

Example:

```
LIB "curvepar.lib";
ring r=0,(x,y),ds;
ideal i=x14-x4y7-y11;
IntersectionMatrix(i);
⇒ 0,1,1,1,7,
⇒ 0,0,1,1,7,
⇒ 0,0,0,1,7,
⇒ 0,0,0,0,7,
⇒ 0,0,0,0,0
```

D.6.10.9 ContactMatrix

Procedure from library `curvepar.lib` (see [Section D.6.10 \[curvepar.lib\]](#), page 1686).

Usage: `ContactMatrix(I)`; I ideal

Assume: i is the defining ideal of a (reducible) plane curve singularity.

Return: intmat N of the contact matrix of the branches of the curve.

Example:

```
LIB "curvepar.lib";
ring r=0,(x,y),ds;
ideal i=x14-x4y7-y11;
ContactMatrix(i);
⇒ 0,1,1,1,1,
⇒ 1,0,1,1,1,
⇒ 1,1,0,1,1,
⇒ 1,1,1,0,1,
⇒ 1,1,1,1,0
```

D.6.10.10 plainInvariants

Procedure from library `curvepar.lib` (see [Section D.6.10 \[curvepar.lib\]](#), page 1686).

Usage: `plainInvariants(i)`; i ideal

Assume: i is the defining ideal of a (reducible) plane curve singularity.

Return: list L of charts. $L[j]$ is the invariants of the j th branch and the last entry of L is a list containing the intersection matrix, contact matrix, resolution graph of the curve.
 $L[j][1]$: intvec (characteristic exponents of the j th branch) $L[j][2]$: intvec (generators of the semigroup of the j th branch) $L[j][3]$: intvec (first components of the puseux pairs of the j th branch) $L[j][4]$: intvec (second components of the puseux pairs of the j th branch) $L[j][5]$: int (degree of conductor of the j th branch) $L[j][6]$: intvec (multiplicity sequence of the j th branch. $L[\text{last}][1]$: intmat (intersection matrix of the branches) $L[\text{last}][2]$: intmat (contact matrix of the branches) $L[\text{last}][3]$: intmat (resolution graph of the curve)

Example:

```

D.6.11 deform.lib

Library: deform.lib

Purpose: Miniversal Deformation of Singularities and Modules

Author: Bernd Martin, email: martin@math.tu-cottbus.de

Procedures:

D.6.11.1 versal

Procedure from library `deform.lib` (see [Section D.6.11 \[deform.lib\]](#), page 1696).

Usage: `versal(Fo[d,any]);` Fo=ideal, d=int, any=list

Compute: miniversal deformation of Fo up to degree d (default d=100),

Return: list L of 4 rings:
 L[1] extending the basering Po by new variables given by "A,B,.. " (deformation parameters); the new variables precede the old ones, the ordering is the product of "ls" and "ord(Po)"
 L[2] = L[1]/Fo extending Qo=Po/Fo,
 L[3] = the embedding ring of the versal base space,
 L[4] = L[1]/Js extending L[3]/Js.
 In the ring L[1] the following matrices are stored:
 Js = giving the versal base space (obstructions),
 Fs = giving the versal family of Fo,
 Rs = giving the lifting of Ro=syz(Fo).
 If d is defined (!=0), it computes up to degree d.
 If 'any' is defined and any[1] is no string, interactive version.
 Otherwise 'any' is interpreted as a list of predefined strings:
 "my","param","order","out":
 ("my" internal prefix, "param" is a letter (e.g. "A") for the name of the first parameter or (e.g. "A(") for index parameter variables, "order" ordering string for ring extension), "out" name of output file).

Note: `printlevel < 0` no additional output,
`printlevel >=0,1,2,..` informs you, what is going on;
 this proc uses 'execute'.

Example:

```
LIB "deform.lib";
int p          = printlevel;
printlevel     = 0;
ring r1        = 0,(x,y,z,u,v),ds;
matrix m[2][4] = x,y,z,u,y,z,u,v;
ideal Fo       = minor(m,2);
// cone over rational normal curve of degree 4
list L=versal(Fo);
⇨ // ready: T_1 and T_2
⇨ // start computation in degree 2.
⇨
⇨
⇨ // 'versal' returned a list, say L, of four rings. In L[1] are stored:
⇨ //   as matrix Fs: Equations of total space of the miniversal deformation\
,
⇨ //   as matrix Js: Equations of miniversal base space,
⇨ //   as matrix Rs: syzygies of Fs mod Js.
⇨ // To access these data, type
⇨   def Px=L[1]; setring Px; print(Fs); print(Js); print(Rs);
⇨
⇨ // L[2] = L[1]/Fo extending Qo=Po/Fo,
⇨ // L[3] = the embedding ring of the versal base space,
```

```

```

D.6.11.2 mod_versal

Procedure from library `deform.lib` (see [Section D.6.11 \[deform.lib\]](#), page 1696).

Usage: `mod_versal(Mo,Io[,d,any]);` Io=ideal, Mo=module, d=int, any =list

Compute: miniversal deformation of `coker(Mo)` over $Qo=Po/Io$, $Po=basering$;

Return: list L of 4 rings:

L[1] extending the basering Po by new variables given by "A,B,..", (deformation parameters); the new variables precede the old ones, the ordering is the product of "ls" and "ord(Po)"

L[2] = L[1]/Io extending Qo ,

L[3] = the embedding ring of the versal base space,

L[4] = L[1]/(Io+Js) ring of the versal deformation of `coker(Ms)`.

In the ring L[1] the following matrices are stored:

Js = giving the versal base space (obstructions),

Fs = giving the versal family of Mo,

Rs = giving the lifting of syzygies $Lo=syz(Mo)$. If d is defined ($d \neq 0$), it computes up to degree d.

If 'any' is defined and any[1] is no string, interactive version.

Otherwise 'any' is interpreted as a list of predefined strings: "my","param","order","out":

("my" internal prefix, "param" is a letter (e.g. "A") for the name of the first parameter or (e.g. "A(") for index parameter variables, "order" ordering string for ring extension), "out" name of output file).

Note: `printlevel < 0` no additional output,
`printlevel >=0,1,2,..` informs you, what is going on,
 this proc uses 'execute'.

Example:

```
LIB "deform.lib";
int p = printlevel;
printlevel = 1;
ring Ro = 0,(x,y),wp(3,4);
ideal Io = x4+y3;
matrix Mo[2][2] = x2,y,-y2,x2;
list L = mod_versal(Mo,Io);
⇒ // vdim (Ext^2) = 4
⇒ // vdim (Ext^1) = 4
⇒ // ready: Ext1 and Ext2
⇒ // Ext1 is quasi-homogeneous represented: 3,6,1,4
⇒ // infinitesimal extension
⇒ x2-Ax-B, y+Cx+D,
⇒ -y2+Cxy+Dy,x2+Ax+B
⇒ // start deg = 2
⇒ // start deg = 3
⇒ // start deg = 4
⇒ // start deg = 5
⇒ // finished in degree
⇒ 5
⇒ // quasi-homogeneous weights of miniversal base
⇒ 3,
```

```

⇒ 6,
⇒ 1,
⇒ 4
⇒
⇒ // 'mod_versal' returned a list, say L, of four rings. In L[2] are stored\
:
⇒ // as matrix Ms: presentation matrix of the deformed module,
⇒ // as matrix Ls: lifted syzygies,
⇒ // as matrix Js: Equations of total space of miniversal deformation
⇒ // To access these data, type
⇒      def Qx=L[2]; setring Qx; print(Ms); print(Ls); print(Js);
⇒
def Qx=L[2]; setring Qx;

⇒ 0,
⇒ 0
printlevel = p;
if (defined(Px)) {kill Px,Qx,So;}

```

D.6.11.3 lift_kbase

Procedure from library `deform.lib` (see [Section D.6.11 \[deform.lib\]](#), page 1696).

Usage: lift_kbase(N,M); N,M=poly/ideal/vector/module

Return: matrix A, coefficient matrix expressing N as linear combination of k-basis of M. Let the k-basis have k elements and size(N)=c columns. Then A satisfies:
 $\text{matrix}(\text{reduce}(N,\text{std}(M)),k,c) = \text{matrix}(\text{kbase}(\text{std}(M)))^*A$

Assume: $\dim(M)=0$ and the monomial ordering is a well ordering or the last block of the ordering is c or C

Example:

```

LIB "deform.lib";
ring R=0,(x,y),ds;
module M=[x2,xy],[y2,xy],[0,xx],[0,yy];
module N=[x3+xy,x],[x,x+y2];
print(M);
⇒ x2,y2,0, 0,
⇒ xy,xy,x2,y2
module kb=kbase(std(M));
print(kb);
⇒ y2,xy,y,x,1,0,0,0,
⇒ 0, 0, 0,0,0,y,x,1
print(N);
⇒ xy+x3,x,
⇒ x,      x+y2

```

```

matrix A=lift_kbase(N,M);
print(A);
↳ 0,0,
↳ 1,0,
↳ 0,0,
↳ 0,1,
↳ 0,0,
↳ 0,0,
↳ 1,1,
↳ 0,0
matrix(reduce(N,std(M)),nrows(kb),ncols(A)) - matrix(kbase(std(M)))*A;
↳ _[1,1]=0
↳ _[1,2]=0
↳ _[2,1]=0
↳ _[2,2]=0

```

D.6.11.4 lift_rel_kb

Procedure from library `deform.lib` (see [Section D.6.11 \[deform.lib\]](#), page 1696).

Usage: `lift_rel_kb(N,M[,kbaseM,p]);`

Assume: `[p` a monomial `]` or the product of all variables
`N`, `M` modules of same rank, `M` depending only on variables not in `p` and `vdim(M)` is finite in this ring,
`[kbaseM` the kbase of `M` in the subring given by variables not in `p` `]`
warning: these assumptions are not checked by the procedure

Return: matrix `A`, whose `j`-th columns present the coeff's of `N[j]` in `kbaseM`, i.e. `kbaseM*A = reduce(N,std(M))`

Example:

```

LIB "deform.lib";
ring r=0,(A,B,x,y),dp;
module M = [x2,xy],[xy,y3],[y2],[0,x];
module kbaseM = [1],[x],[xy],[y],[0,1],[0,y],[0,y2];
poly f=xy;
module N = [AB,BBy],[A3xy+x4,AB*(1+y2)];
matrix A = lift_rel_kb(N,M,kbaseM,f);
print(A);
↳ AB,0,
↳ 0, 0,
↳ 0, A3,
↳ 0, 0,
↳ 0, AB,
↳ B2,0,
↳ 0, AB
"TEST:";
↳ TEST:
print(matrix(kbaseM)*A-matrix(reduce(N,std(M))));
↳ 0,0,
↳ 0,0

```

D.6.12 equising_lib

Library: equising.lib

Purpose: Equisingularity Stratum of a Family of Plane Curves

Author: Christoph Lossen, lossen@mathematik.uni-kl.de
Andrea Mindnich, mindnich@mathematik.uni-kl.de

Procedures:

D.6.12.1 tau_es

Procedure from library `equising.lib` (see [Section D.6.12 \[equising_lib\]](#), page 1701).

Usage: `tau_es(f); f poly`

Assume: `f` is a reduced bivariate polynomial, the basering has precisely two variables, is local and no `qring`.

Return: `int`, the codimension of the μ -const stratum in the semi-universal deformation base.

Note: `printlevel >= 1` displays additional information.
When called with any additional parameter, the computation of the Milnor number is avoided (no check for NND).

Example:

```
LIB "equising.lib";
ring r=32003,(x,y),ds;
poly f=(x4-y4)^2-x10;
tau_es(f);
↦ 42
```

See also: [Section D.6.12.2 \[esIdeal\]](#), page 1702; [Section D.6.15.6 \[invariants\]](#), page 1731; [Section D.6.20.15 \[tjurina\]](#), page 1768.

D.6.12.2 esIdeal

Procedure from library `equising.lib` (see [Section D.6.12 \[equising_lib\]](#), page 1701).

Usage: `esIdeal(f[,any]); f poly`

Assume: `f` is a reduced bivariate polynomial, the basering has precisely two variables, is local and no `qring`, and the characteristic of the ground field does not divide `mult(f)`.

Return: if called with only one parameter: list of two ideals,
 `_[1]`: equisingularity ideal of `f` (in sense of Wahl),
 `_[2]`: ideal of equisingularity with fixed position of the singularity;
 if called with more than one parameter: list of three ideals,
 `_[1]`: equisingularity ideal of `f` (in sense of Wahl)
 `_[2]`: ideal of equisingularity with fixed position of the singularity;
 `_[3]`: ideal of all `g` such that the deformation defined by `f+eg` (`e^2=0`) is isomorphic to an equisingular deformation of `V(f)` with all equimultiple sections being trivial.

Note: if some of the above condition is not satisfied then return value is `list(0,0)`.

Example:

```

LIB "equising.lib";
ring r=0,(x,y),ds;
poly f=x7+y7+(x-y)^2*x2y2;
list K=esIdeal(f);
↳ polynomial is Newton degenerate !
↳
↳ //
↳ // versal deformation with triv. section
↳ // =====
↳ //
↳ //
↳ // Compute equisingularity Stratum over Spec(C[t]/t^2)
↳ // =====
↳ //
↳ // finished
↳ //
option(redSB);
// Wahl's equisingularity ideal:
std(K[1]);
↳ _[1]=4x4y-10x2y3+6xy4+21x6+14y6
↳ _[2]=4x3y2-6x2y3+2xy4+7x6
↳ _[3]=x2y4-xy5
↳ _[4]=x7
↳ _[5]=xy6
↳ _[6]=y7
ring rr=0,(x,y),ds;
poly f=x4+4x3y+6x2y2+4xy3+y4+2x2y15+4xy16+2y17+xy23+y24+y30+y31;
list K=esIdeal(f);
↳ polynomial is Newton degenerate !
↳
↳ //
↳ // versal deformation with triv. section

↳ //
↳ //
↳ // Compute equisingularity Stratum over Spec(C[t]/t^2)
↳ // =====
↳ //
↳ // finished
↳ //
vdim(std(K[1]));
↳ 68
// the latter should be equal to:
tau_es(f);
↳ 68

```

See also: [Section D.6.12.3 \[esStratum\]](#), page 1703; [Section D.6.12.1 \[tau-es\]](#), page 1702.

D.6.12.3 esStratum

Procedure from library `equising.lib` (see [Section D.6.12 \[equising-lib\]](#), page 1701).

Usage: `esStratum(F[,m,L]);` F poly, m int, L list

- Assume:** F defines a deformation of a reduced bivariate polynomial f and the characteristic of the basering does not divide $\text{mult}(f)$.
 If nv is the number of variables of the basering, then the first $\text{nv}-2$ variables are the deformation parameters.
 If the basering is a qring, $\text{ideal}(\text{basing})$ must only depend on the deformation parameters.
- Compute:** equations for the stratum of equisingular deformations with fixed (trivial) section.
- Return:** list l : either consisting of a list and an integer, where
 $l[1][1]=\text{ideal}$ defining the equisingularity stratum
 $l[1][2]=\text{ideal}$ defining the part of the equisingularity stratum where all equimultiple sections through the non-nodes of the reduced total transform are trivial sections
 $l[2]=1$ if some error has occurred, $l[2]=0$ otherwise;
 or consisting of a ring and an integer, where
 $l[1]=\text{ESSring}$ is a ring extension of basering containing the ideal ES (describing the ES-stratum), the ideal ES_all_triv (describing the part with trivial equimultiple sections) and the polynomial $p_F=F$,
 $l[2]=1$ if some error has occurred, $l[2]=0$ otherwise.
- Note:** L is supposed to be the output of hnexpansion (with the given ordering of the variables appearing in f).
 If m is given, the ES Stratum over $A/\text{maxideal}(m)$ is computed.
 This procedure uses `execute` or calls a procedure using `execute`. `printlevel>=2` displays additional information.

Example:

```
LIB "equising.lib";
int p=printlevel;
printlevel=1;
ring r = 0,(a,b,c,d,e,f,g,x,y),ds;
poly F = (x2+2xy+y2+x5)+ax+by+cx2+dxy+ey2+fx3+gx4;
list M = esStratum(F);
M[1][1];
  ↳ _[1]=g
  ↳ _[2]=f
  ↳ _[3]=b
  ↳ _[4]=a
  ↳ _[5]=-4c+4d-4e+d2-4ce
printlevel=3;      // displays additional information
esStratum(F,2) ; // ES-stratum over Q[a,b,c,d,e,f,g] / <a,b,c,d,e,f,g>^2
  ↳ //

See also: [Section D.6.12.2 \[esIdeal\]](#), page 1702; [Section D.6.12.4 \[isEquisising\]](#), page 1706.

D.6.12.4 isEquisising

Procedure from library `equisising.lib` (see [Section D.6.12 \[equisising_lib\]](#), page 1701).

Usage: `isEquisising(F[,m,L]);` F poly, m int, L list

Assume: F defines a deformation of a reduced bivariate polynomial f and the characteristic of the basering does not divide `mult(f)`.

If `nv` is the number of variables of the basering, then the first `nv-2` variables are the deformation parameters.

If the basering is a qring, `ideal(basing)` must only depend on the deformation parameters.

Compute: tests if the given family is equisingular along the trivial section.

Return: int: 1 if the family is equisingular, 0 otherwise.

Note: L is supposed to be the output of `hnexpansion` (with the given ordering of the variables appearing in f).

If m is given, the family is considered over $A/\text{maxideal}(m)$.

This procedure uses `execute` or calls a procedure using `execute`. `printlevel>=2` displays additional information.

Example:

```

LIB "equisising.lib";
ring r = 0,(a,b,x,y),ds;
poly F = (x2+2xy+y2+x5)+ay3+bx5;
isEquisising(F);
⇒ 0
ideal I = ideal(a);
qring q = std(I);
poly F = imap(r,F);
isEquisising(F);
⇒ 1
ring rr=0,(A,B,C,x,y),ls;
poly f=x7+y7+(x-y)^2*x2y2;
poly F=f+A*y*diff(f,x)+B*x*diff(f,x);
isEquisising(F);
⇒ 0

```

```
isEquisising(F,2);    // computation over  $\mathbb{Q}[a,b] / \langle a,b \rangle^2$ 
 $\mapsto 1$ 
```

D.6.12.5 control_Matrix

Procedure from library `equisising.lib` (see [Section D.6.12 \[equisising_lib\]](#), page 1701).

Assume: `L` is the output of `multsequence(hnexpansion(f))`.

Return: list `M` of 4 `intmat`'s:

- `M[1]` contains the multiplicities at the respective infinitely near points `p[i,j]` (`i=step of blowup+1`, `j=branch`) – if branches `j=k,...,k+m` pass through the same `p[i,j]` then the multiplicity is stored in `M[1][k,j]`, while `M[1][k+1]=...=M[1][k+m]=0`.
- `M[2]` contains the number of branches meeting at `p[i,j]` (again, the information is stored according to the above rule)
- `M[3]` contains the information about the splitting of `M[1][i,j]` with respect to different tangents of branches at `p[i,j]` (information is stored only for minimal `j>=k` corresponding to a new tangent direction). The entries are the sum of multiplicities of all branches with the respective tangent.
- `M[4]` contains the maximal sum of higher multiplicities for a branch passing through `p[i,j]` (= degree Bound for blowing up)

Note: the branches are ordered in such a way that only consecutive branches can meet at an infinitely near point.
the final rows of the matrices `M[1],...,M[3]` is `(1,1,1,...,1)`, and correspond to infinitely near points such that the strict transforms of the branches are smooth and intersect the exceptional divisor transversally.

See also: [Section D.6.15.8 \[multsequence\]](#), page 1732.

D.6.13 gmssing_lib

Library: `gmssing.lib`

Purpose: Gauss-Manin System of Isolated Singularities

Author: Mathias Schulze, `mschulze at mathematik.uni-kl.de`

Overview: A library for computing invariants related to the Gauss-Manin system of an isolated hypersurface singularity.

References:

Procedures: See also: [Section 7.5.4 \[dmod_lib\]](#), page 401; [Section D.6.14 \[gmsspoly_lib\]](#), page 1722; [Section D.6.17 \[monodromy_lib\]](#), page 1742; [Section D.6.22 \[spectrum_lib\]](#), page 1777.

D.6.13.1 gmsring

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing-lib\]](#), page 1707).

Usage: `gmsring(t,s);` poly `t`, string `s`

Assume: characteristic 0; local degree ordering;
isolated critical point 0 of `t`

Return:

```
ring G; Gauss-Manin system of t with variable s
poly gmspoly=t;
ideal gmsjacob; Jacobian ideal of t
ideal gmsstd; standard basis of Jacobian ideal
matrix gmsmatrix; matrix(gmsjacob)*gmsmatrix==matrix(gmsstd)
ideal gmsbasis; monomial vector space basis of Jacobian algebra
int Gmssing::gmsmaxdeg; maximal weight of variables
```

Note: `gmsbasis` is a $C[[s]]$ -basis of H^* and $[t,s]=s^2$

Example:

```
LIB "gmssing.lib";
ring @R=0,(x,y),ds;
poly t=x5+x2y2+y5;
def G=gmsring(t,"s");
setring(G);
gmspoly;
  ↳ x2y2+x5+y5
print(gmsjacob);
  ↳ 2xy2+5x4,
  ↳ 2x2y+5y4
print(gmsstd);
  ↳ 2x2y+5y4,
  ↳ 5x5-5y5,
  ↳ 2xy2+5x4,
  ↳ 10y6+25x3y4
print(gmsmatrix);
  ↳ 0,x, 1,-2xy,
  ↳ 1,-y,0,2y2+5x3
print(gmsbasis);
  ↳ y5,
  ↳ y4,
  ↳ y3,
  ↳ y2,
  ↳ xy,
  ↳ y,
  ↳ x4,
  ↳ x3,
  ↳ x2,
  ↳ x,
  ↳ 1
Gmssing::gmsmaxdeg;
  ↳ 1
```

D.6.13.2 gmsnf

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing.lib\]](#), page 1707).

Usage: `gmsnf(p,K);` poly p , int K

Assume: basering returned by `gmsring`

Return: list nf ;
ideal $nf[1]$; projection of p to $\langle gmsbasis \rangle C[[s]] \bmod s^{(K+1)}$ ideal $nf[2]$; $p == nf[1] + nf[2]$

Note: computation can be continued by setting $p = nf[2]$

Example:

```
LIB "gmssing.lib";
ring R=0,(x,y),ds;
poly t=x5+x2y2+y5;
def G=gmsring(t,"s");
setring(G);
list l0=gmsnf(gmspoly,0);
print(l0[1]);
 $\mapsto -1/2y^5$ 
list l1=gmsnf(gmspoly,1);
print(l1[1]);
 $\mapsto -1/2y^5 + 1/2s$ 
list l=gmsnf(l0[2],1);
print(l[1]);
 $\mapsto 1/2s$ 
```

D.6.13.3 gmscoeffs

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing.lib\]](#), page 1707).

Usage: `gmscoeffs(p,K);` poly p , int K

Assume: basering constructed by `gmsring`

Return: list l ;
matrix $l[1]$; $C[[s]]$ -basis representation of $p \bmod s^{(K+1)}$
ideal $l[2]$; $p == \text{matrix}(gmsbasis) * l[1] + l[2]$

Note: computation can be continued by setting $p = l[2]$

Example:

```
LIB "gmssing.lib";
ring R=0,(x,y),ds;
poly t=x5+x2y2+y5;
def G=gmsring(t,"s");
setring(G);
list l0=gmscoeffs(gmspoly,0);
print(l0[1]);
 $\mapsto -1/2,$ 
 $\mapsto 0,$ 
 $\mapsto 0,$ 
 $\mapsto 0,$ 
 $\mapsto 0,$ 
```

```

↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 0
list l1=gmscoeffs(gmspoly,1);
print(l1[1]);
↳ -1/2,
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 1/2s
list l=gmscoeffs(l0[2],1);
print(l[1]);
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 0,
↳ 1/2s

```

D.6.13.4 bernstein

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing.lib\]](#), page 1707).

Usage: `bernstein(t); poly t`

Assume: `characteristic 0; local degree ordering;`
 `isolated critical point 0 of t`

Return:

```

list bs; Bernstein-Sato polynomial b(s) of t
ideal bs[1];
number bs[1][i]; i-th root of b(s)
intvec bs[2];
int bs[2][i]; multiplicity of i-th root of b(s)

```

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
poly t=x5+x2y2+y5;
bernstein(t);
↳ [1]:

```

```

⇒  _[1] = -13/10
⇒  _[2] = -11/10
⇒  _[3] = -1
⇒  _[4] = -9/10
⇒  _[5] = -7/10
⇒  _[6] = -1/2
⇒  [2] :
⇒      1, 1, 2, 1, 1, 2

```

D.6.13.5 monodromy

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing_lib\]](#), page 1707).

Usage: `monodromy(t);` poly t

Assume: characteristic 0; local degree ordering;
isolated critical point 0 of t

Return:

```

list l; Jordan data jordan(M) of monodromy matrix  $\exp(-2\pi i M)$ 
ideal l[1];
number l[1][i]; eigenvalue of i-th Jordan block of M
intvec l[2];
int l[2][i]; size of i-th Jordan block of M
intvec l[3];
int l[3][i]; multiplicity of i-th Jordan block of M

```

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
poly t=x5+x2y2+y5;
monodromy(t);
⇒ [1] :
⇒  _[1] = 1/2
⇒  _[2] = 7/10
⇒  _[3] = 9/10
⇒  _[4] = 1
⇒  _[5] = 11/10
⇒  _[6] = 13/10
⇒ [2] :
⇒  2, 1, 1, 1, 1, 1
⇒ [3] :
⇒  1, 2, 2, 1, 2, 2

```

See also: [Section D.3.2 \[linalg_lib\]](#), page 988; [Section D.6.17 \[monodromy_lib\]](#), page 1742.

D.6.13.6 spectrum

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing_lib\]](#), page 1707).

Usage: `spectrum(t);` poly t

Assume: characteristic 0; local degree ordering;
isolated critical point 0 of t

Return:

```

list sp; singularity spectrum of t
ideal sp[1];
number sp[1][i]; i-th spectral number
intvec sp[2];
int sp[2][i]; multiplicity of i-th spectral number

```

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
poly t=x5+x2y2+y5;
spprint(spectrum(t));
↦ (-1/2,1),(-3/10,2),(-1/10,2),(0,1),(1/10,2),(3/10,2),(1/2,1)

```

See also: [Section D.6.22 \[spectrum_lib\]](#), page 1777.

D.6.13.7 sppairs

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing_lib\]](#), page 1707).

Usage: sppairs(t); poly t

Assume: characteristic 0; local degree ordering;
isolated critical point 0 of t

Return:

```

list spp; spectral pairs of t
ideal spp[1];
number spp[1][i]; V-filtration index of i-th spectral pair
intvec spp[2];
int spp[2][i]; weight filtration index of i-th spectral pair
intvec spp[3];
int spp[3][i]; multiplicity of i-th spectral pair

```

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
poly t=x5+x2y2+y5;
sppprint(sppairs(t));
↦ ((-1/2,2),1),((-3/10,1),2),((-1/10,1),2),((0,1),1),((1/10,1),2),((3/10,1)\
,2),((1/2,0),1)

```

See also: [Section D.6.22 \[spectrum_lib\]](#), page 1777.

D.6.13.8 vfilt

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing_lib\]](#), page 1707).

Usage: vfilt(t); poly t

Assume: characteristic 0; local degree ordering;
isolated critical point 0 of t

Return:

```

list v; V-filtration on  $H''/s^*H''$ 
ideal v[1];
number v[1][i]; V-filtration index of i-th spectral number
intvec v[2];

```

`int v[2][i];` multiplicity of i -th spectral number
`list v[3];`
`module v[3][i];` vector space of i -th graded part in terms of $v[4]$
`ideal v[4];` monomial vector space basis of H''/s^*H''
`ideal v[5];` standard basis of Jacobian ideal

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
poly t=x5+x2y2+y5;
vfilt(t);
↳ [1]:
↳   _[1]=-1/2
↳   _[2]=-3/10
↳   _[3]=-1/10
↳   _[4]=0
↳   _[5]=1/10
↳   _[6]=3/10
↳   _[7]=1/2
↳ [2]:
↳   1,2,2,1,2,2,1
↳ [3]:

⇒  _[1]=2x2y+5y4
⇒  _[2]=5x5-5y5
⇒  _[3]=2xy2+5x4
⇒  _[4]=10y6+25x3y4

```

See also: [Section D.6.22 \[spectrum.lib\]](#), page 1777.

D.6.13.9 vwfilt

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing.lib\]](#), page 1707).

Usage: `vwfilt(t); poly t`

Assume: characteristic 0; local degree ordering;
isolated critical point 0 of `t`

Return:

```

list vw; weighted V-filtration on  $H''/s^*H''$ 
ideal vw[1];
number vw[1][i]; V-filtration index of i-th spectral pair
intvec vw[2];
int vw[2][i]; weight filtration index of i-th spectral pair
intvec vw[3];
int vw[3][i]; multiplicity of i-th spectral pair
list vw[4];
module vw[4][i]; vector space of i-th graded part in terms of vw[5]
ideal vw[5]; monomial vector space basis of  $H''/s^*H''$ 
ideal vw[6]; standard basis of Jacobian ideal

```

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
poly t=x5+x2y2+y5;
vwfilt(t);
⇒ [1]:

D.6.13.10 tmatrix

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing_lib\], page 1707](#)).

Usage: `tmatrix(t);` poly t

Assume: characteristic 0; local degree ordering;
isolated critical point 0 of t

Return:

list $l=A0,A1,T,M$;
matrix $A0,A1$; $t=A0+s*A1+s^2*(d/ds)$ on H'' w.r.t. $C[[s]]$ -basis $M*T$
module T ; C -basis of C^μ
ideal M ; monomial C -basis of H''/sH''

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
poly t=x5+x2y2+y5;
list l=tmatrix(t);
print(l[1]);

D.6.13.11 endvfilt

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing_lib\]](#), page 1707).

Usage: `endvfilt(v);` list `v`

Assume: `v` returned by `vfilt`

Return:

list `ev`; V-filtration on Jacobian algebra

```

ideal ev[1];
  number ev[1][i]; i-th V-filtration index
intvec ev[2];
  int ev[2][i]; i-th multiplicity
list ev[3];
  module ev[3][i]; vector space of i-th graded part in terms of ev[4]
ideal ev[4]; monomial vector space basis of Jacobian algebra
ideal ev[5]; standard basis of Jacobian ideal

```

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
poly t=x5+x2y2+y5;
endvfilt(vfilt(t));
↳ [1]:
↳   _[1]=0

```

D.6.13.12 sppnf

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing.lib\]](#), page 1707).

Usage: `sppnf(list(a,w[m]));` ideal `a`, intvec `w`, intvec `m`

Assume: `ncols(a)==size(w)==size(m)`

Return: order $(a[i][,w[i]])$ with multiplicity $m[i]$ lexicographically

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
list sp=list(ideal(-1/2,-3/10,-3/10,-1/10,-1/10,0,1/10,1/10,3/10,3/10,1/2),
intvec(2,1,1,1,1,1,1,1,1,1,0));
sppprint(sppnf(sp));
↳ ((-1/2,2),1),((-3/10,1),2),((-1/10,1),2),((0,1),1),((1/10,1),2),((3/10,1)\
,2),((1/2,0),1)

```

D.6.13.13 sppprint

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing.lib\]](#), page 1707).

Usage: `sppprint(spp);` list `spp`

Return: string `s`; spectral pairs `spp`

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
list spp=list(ideal(-1/2,-3/10,-1/10,0,1/10,3/10,1/2),intvec(2,1,1,1,1,1,0),
intvec(1,2,2,1,2,2,1));
sppprint(spp);
↳ ((-1/2,2),1),((-3/10,1),2),((-1/10,1),2),((0,1),1),((1/10,1),2),((3/10,1)\
,2),((1/2,0),1)

```

D.6.13.14 spadd

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing.lib\]](#), page 1707).

Usage: `spadd(sp1,sp2);` list `sp1`, list `sp2`

Return: list `sp`; sum of spectra `sp1` and `sp2`

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
list sp1=list(ideal(-1/2,-3/10,-1/10,0,1/10,3/10,1/2),intvec(1,2,2,1,2,2,1));
spprint(sp1);

```

```

⇒ (-1/2,1), (-3/10,2), (-1/10,2), (0,1), (1/10,2), (3/10,2), (1/2,1)
list sp2=list(ideal(-1/6,1/6),intvec(1,1));
spprint(sp2);
⇒ (-1/6,1), (1/6,1)
spprint(spadd(sp1,sp2));
⇒ (-1/2,1), (-3/10,2), (-1/6,1), (-1/10,2), (0,1), (1/10,2), (1/6,1), (3/10,2), (1/2,1)

```

D.6.13.15 spsub

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing.lib\]](#), page 1707).

Usage: `spsub(sp1,sp2);` list sp1, list sp2

Return: list sp; difference of spectra sp1 and sp2

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
list sp1=list(ideal(-1/2,-3/10,-1/10,0,1/10,3/10,1/2),intvec(1,2,2,1,2,2,1));
spprint(sp1);
⇒ (-1/2,1), (-3/10,2), (-1/10,2), (0,1), (1/10,2), (3/10,2), (1/2,1)
list sp2=list(ideal(-1/6,1/6),intvec(1,1));
spprint(sp2);
⇒ (-1/6,1), (1/6,1)
spprint(spsub(sp1,sp2));
⇒ (-1/2,1), (-3/10,2), (-1/6,-1), (-1/10,2), (0,1), (1/10,2), (1/6,-1), (3/10,2), (1/2,1)

```

D.6.13.16 spmul

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing.lib\]](#), page 1707).

Usage: `spmul(sp0,k);` list sp0, int[vec] k

Return: list sp; linear combination of spectra sp0 with coefficients k

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
list sp=list(ideal(-1/2,-3/10,-1/10,0,1/10,3/10,1/2),intvec(1,2,2,1,2,2,1));
spprint(sp);
⇒ (-1/2,1), (-3/10,2), (-1/10,2), (0,1), (1/10,2), (3/10,2), (1/2,1)
spprint(spmul(sp,2));
⇒ (-1/2,2), (-3/10,4), (-1/10,4), (0,2), (1/10,4), (3/10,4), (1/2,2)
list sp1=list(ideal(-1/6,1/6),intvec(1,1));
spprint(sp1);
⇒ (-1/6,1), (1/6,1)
list sp2=list(ideal(-1/3,0,1/3),intvec(1,2,1));
spprint(sp2);
⇒ (-1/3,1), (0,2), (1/3,1)
spprint(spmul(list(sp1,sp2),intvec(1,2)));
⇒ (-1/3,2), (-1/6,1), (0,4), (1/6,1), (1/3,2)

```

D.6.13.17 spissemicont

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing_lib\]](#), page 1707).

Usage: `spissemicont(sp[1]);` list sp, int opt

Return:

int k=
 1; if sum of sp is positive on all intervals $[a, a+1)$ [and $(a, a+1]$
 0; if sum of sp is negative on some interval $[a, a+1)$ [or $(a, a+1]$

Example:

```
LIB "gmssing.lib";
ring R=0,(x,y),ds;
list sp1=list(ideal(-1/2,-3/10,-1/10,0,1/10,3/10,1/2),intvec(1,2,2,1,2,2,1));
spprint(sp1);
↪ (-1/2,1),(-3/10,2),(-1/10,2),(0,1),(1/10,2),(3/10,2),(1/2,1)
list sp2=list(ideal(-1/6,1/6),intvec(1,1));
spprint(sp2);
↪ (-1/6,1),(1/6,1)
spissemicont(spsub(sp1,spmul(sp2,3)));
↪ 1
spissemicont(spsub(sp1,spmul(sp2,4)));
↪ 0
```

D.6.13.18 spsemicont

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing_lib\]](#), page 1707).

Usage: `spsemicont(sp0,sp,k[1]);` list sp0, list sp

Return:

list l;
 intvec l[i]; if the spectra sp0 occur with multiplicities k
 in a deformation of a [quasihomogeneous] singularity
 with spectrum sp then $k \leq l[i]$

Example:

```
LIB "gmssing.lib";
ring R=0,(x,y),ds;
list sp0=list(ideal(-1/2,-3/10,-1/10,0,1/10,3/10,1/2),intvec(1,2,2,1,2,2,1));
spprint(sp0);
↪ (-1/2,1),(-3/10,2),(-1/10,2),(0,1),(1/10,2),(3/10,2),(1/2,1)
list sp1=list(ideal(-1/6,1/6),intvec(1,1));
spprint(sp1);
↪ (-1/6,1),(1/6,1)
list sp2=list(ideal(-1/3,0,1/3),intvec(1,2,1));
spprint(sp2);
↪ (-1/3,1),(0,2),(1/3,1)
list sp=sp1,sp2;
list l=spsemicont(sp0,sp);
l;
↪ [1]:
↪ 3
↪ [2]:
```

```

    ↪      2,1
    spissemicont(spsub(sp0,spmul(sp,l[1])));
    ↪      1
    spissemicont(spsub(sp0,spmul(sp,l[1]-1)));
    ↪      1
    spissemicont(spsub(sp0,spmul(sp,l[1]+1)));
    ↪      0

```

D.6.13.19 spmilnor

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing_lib\]](#), page 1707).

Usage: `spmilnor(sp);` list `sp`

Return: `int mu;` Milnor number of spectrum `sp`

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
list sp=list(ideal(-1/2,-3/10,-1/10,0,1/10,3/10,1/2),intvec(1,2,2,1,2,2,1));
spprint(sp);
↪ (-1/2,1),(-3/10,2),(-1/10,2),(0,1),(1/10,2),(3/10,2),(1/2,1)
spmilnor(sp);
↪ 11

```

D.6.13.20 spgeomgenus

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing_lib\]](#), page 1707).

Usage: `spgeomgenus(sp);` list `sp`

Return: `int g;` geometrical genus of spectrum `sp`

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
list sp=list(ideal(-1/2,-3/10,-1/10,0,1/10,3/10,1/2),intvec(1,2,2,1,2,2,1));
spprint(sp);
↪ (-1/2,1),(-3/10,2),(-1/10,2),(0,1),(1/10,2),(3/10,2),(1/2,1)
spgeomgenus(sp);
↪ 6

```

D.6.13.21 spgamma

Procedure from library `gmssing.lib` (see [Section D.6.13 \[gmssing_lib\]](#), page 1707).

Usage: `spgamma(sp);` list `sp`

Return: `number gamma;` gamma invariant of spectrum `sp`

Example:

```

LIB "gmssing.lib";
ring R=0,(x,y),ds;
list sp=list(ideal(-1/2,-3/10,-1/10,0,1/10,3/10,1/2),intvec(1,2,2,1,2,2,1));
spprint(sp);
↪ (-1/2,1),(-3/10,2),(-1/10,2),(0,1),(1/10,2),(3/10,2),(1/2,1)
spgamma(sp);
↪ 1/240

```

D.6.14 gmspoly_lib

Library: gmspoly.lib

Purpose: Gauss-Manin System of Tame Polynomials

Author: Mathias Schulze, mschulze at mathematik.uni-kl.de

Overview: A library for computing the Gauss-Manin system of a cohomologically tame polynomial f . Schulze's algorithm [Sch05], based on Sabbah's theory [Sab98], is used to compute a good basis of (the Brieskorn lattice of) the Gauss-Manin system and the differential operation of f in terms of this basis. In addition, there is a test for tameness in the sense of Broughton. Tame polynomials can be considered as an affine algebraic analogue of local analytic isolated hypersurface singularities. They have only finitely many critical points, and those at infinity do not give rise to atypical values in a sense depending on the precise notion of tameness considered. Well-known notions of tameness like tameness, M-tameness, Malgrange-tameness, and cohomological tameness, and their relations, are reviewed in [Sab98,8]. For ordinary tameness, see Broughton [Bro88,3]. Sabbah [Sab98] showed that the Gauss-Manin system, the D-module direct image of the structure sheaf, of a cohomologically tame polynomial carries a similar structure as in the isolated singularity case, coming from a Mixed Hodge structure on the cohomology of the Milnor (typical) fibre (see gmssing.lib). The data computed by this library encodes the differential structure of the Gauss-Manin system, and the Mixed Hodge structure of the Milnor fibre over the complex numbers. As a consequence, it yields the Hodge numbers, spectral pairs, and monodromy at infinity.

References:

- [Bro88] S. Broughton: Milnor numbers and the topology of polynomial hypersurfaces. Inv. Math. 92 (1988) 217-241.

Procedures: See also: [Section D.6.13 \[gmssing_lib\]](#), page 1707.

D.6.14.1 isTame

Procedure from library gmspoly.lib (see [Section D.6.14 \[gmspoly_lib\]](#), page 1722).

Usage: isTame(f); poly f

Assume: basering has no variables named w(1),w(2),...

Return:

```
int k=
    1; if f is tame in the sense of Broughton [Bro88,3]
    0; if f is not tame
```

Remarks: procedure implements Proposition 3.1 in [Bro88]

Example:

```
LIB "gmspoly.lib";
ring R=0,(x,y),dp;
isTame(x2y+x);
  ↳ 0
isTame(x3+y3+xy);
  ↳ 1
```

D.6.14.2 goodBasis

Procedure from library `gmspoly.lib` (see [Section D.6.14 \[gmspoly_lib\]](#), page 1722).

Usage: `goodBasis(f); poly f`

Assume: `f` is cohomologically tame in the sense of Sabbah [Sab98,8]

Return:

ring `R`; basering with new variable `s`
 ideal `b`; `[matrix(b)]` is a good basis of the Brieskorn lattice
 matrix `A`; $A(s) = A_0 + s \cdot A_1$ and $t[matrix(b)] = [matrix(b)](A(s) + s^2 \cdot (d/ds))$

Remarks: procedure implements Algorithm 6 in [Sch05]

Example:

```
LIB "gmspoly.lib";
ring R=0,(x,y,z),dp;
poly f=x+y+z+x2y2z2;
def Rs=goodBasis(f);
setring(Rs);
b;
⇒ b[1]=1
⇒ b[2]=s2x-3sx2+x3
⇒ b[3]=5/2x
⇒ b[4]=10s2x2-25/2sx3+5/2x4
⇒ b[5]=-25/4sx+25/4x2
print(jet(A,0));
⇒ 0,0,0,-25/8,0,
⇒ 0,0,0,0, 125/8,
⇒ 1,0,0,0, 0,
⇒ 0,1,0,0, 0,
⇒ 0,0,1,0, 0
print(jet(A/var(1),0));
⇒ 1/2,0,0, 0,0,
⇒ 0, 1,0, 0,0,
⇒ 0, 0,3/2,0,0,
⇒ 0, 0,0, 2,0,
⇒ 0, 0,0, 0,5/2
```

See also: [Section D.6.13 \[gmssing_lib\]](#), page 1707.

D.6.15 hnoether_lib

Library: `hnoether.lib`

Purpose: Hamburger-Noether (Puiseux) Expansion

Authors: Martin Lamm, lamm@mathematik.uni-kl.de
 Christoph Lossen, lossen@mathematik.uni-kl.de

Overview: A library for computing the Hamburger-Noether expansion (analogue of Puiseux expansion over fields of arbitrary characteristic) of a reduced plane curve singularity following [Campillo, A.: Algebroid curves in positive characteristic, Springer LNM 813 (1980)].

The library contains also procedures for computing the (topological) numerical invariants of plane curve singularities.

Procedures:

D.6.15.1 hnexpansion

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `hnexpansion(f, "ess");` `f` poly

Assume: `f` is a bivariate polynomial (in the first 2 ring variables)

Return: list `L`, containing Hamburger-Noether data of `f`: If the computation of the HNE required no field extension, `L` is a list of lists `L[i]` (corresponding to the output of `develop`, applied to a branch of `f`, but the last entry being omitted):

`L[i][1]`; matrix:

Each row contains the coefficients of the corresponding line of the Hamburger-Noether expansion (HNE) for the `i`-th branch. The end of the line is marked in the matrix by the first ring variable (usually `x`).

`L[i][2]`; intvec:

indicating the length of lines of the HNE

`L[i][3]`; int:

0 if the 1st ring variable was transversal (with respect to the `i`-th branch),
1 if the variables were changed at the beginning of the computation,
-1 if an error has occurred.

`L[i][4]`; poly:

the transformed equation of the `i`-th branch to make it possible to extend the Hamburger-Noether data a posteriori without having to do all the previous calculation once again (0 if not needed).

If the computation of the HNE required a field extension, the first entry `L[1]` of the list is a ring, in which a list `hne` of lists (the HN data, as above) and a polynomial `f` (image of `f` over the new field) are stored.

If called with an additional input parameter, `hnexpansion` computes only one representative for each class of conjugate branches (over the ground field active when calling the procedure). In this case, the returned list `L` always has only two entries: `L[1]` is either a list of lists (the HN data) or a ring (as above), and `L[2]` is an integer vector (the number of branches in the respective conjugacy classes).

Note: If `f` is known to be irreducible as a power series, `develop(f)` could be chosen instead to avoid a change of basering during the computations.

Increasing `printlevel` leads to more and more comments.

Having defined a variable `HNDebugOn` leads to a maximum number of comments.

Example:

```
LIB "hnoether.lib";
ring r=0,(x,y),dp;
// First, an example which requires no field extension:
list Hne=hnexpansion(x4-y6);
⇒ // No change of ring necessary, return value is HN expansion.
size(Hne);           // number of branches
⇒ 2
displayHNE(Hne);     // HN expansion of branches
⇒ // Hamburger-Noether development of branch nr.1:
⇒ x = z(1)*y
⇒ y = z(1)^2
⇒
```

```

⇒ // Hamburger-Noether development of branch nr.2:
⇒   x = z(1)*y
⇒   y = -z(1)^2
⇒
param(Hne[1]);          // parametrization of 1st branch
⇒   _[1]=x3
⇒   _[2]=x2
param(Hne[2]);          // parametrization of 2nd branch
⇒   _[1]=-x3
⇒   _[2]=-x2
// An example which requires a field extension:
list L=hnexpansion((x4-y6)*(y2+x4));
⇒
⇒ // 'hnexpansion' created a list of one ring.
⇒ // To see the ring and the data stored in the ring, type (if you assigned
⇒ // the name L to the list):
⇒   show(L);
⇒ // To display the computed HN expansion, type
⇒   def HNring = L[1]; setring HNring; displayHNE(hne);
def R=L[1]; setring R; displayHNE(hne);
⇒ // Hamburger-Noether development of branch nr.1:
⇒   y = (a)*x^2
⇒
⇒ // Hamburger-Noether development of branch nr.2:
⇒   y = (-a)*x^2
⇒
⇒ // Hamburger-Noether development of branch nr.3:
⇒   x = z(1)*y
⇒   y = z(1)^2
⇒
⇒ // Hamburger-Noether development of branch nr.4:
⇒   x = z(1)*y
⇒   y = -z(1)^2
⇒
basing;
⇒ // coefficients: QQ[a]/(a2+1)
⇒ // number of vars : 2
⇒ //           block  1: ordering ls
⇒ //           : names  x y
⇒ //           block  2 : ordering C
setring r; kill R;
// Computing only one representative per conjugacy class:
L=hnexpansion((x4-y6)*(y2+x4),"ess");
⇒
⇒ // 'hnexpansion' created a list of one ring.
⇒ // To see the ring and the data stored in the ring, type (if you assigned
⇒ // the name L to the list):
⇒   show(L);
⇒ // To display the computed HN expansion, type
⇒   def HNring = L[1]; setring HNring; displayHNE(hne);
⇒ // As second entry of the returned list L, you obtain an integer vector,
⇒ // indicating the number of conjugates for each of the computed branches.
def R=L[1]; setring R; displayHNE(hne);

```

```

⇒ // Hamburger-Noether development of branch nr.1:
⇒ y = (a)*x^2
⇒
⇒ // Hamburger-Noether development of branch nr.2:
⇒ x = z(1)*y
⇒ y = z(1)^2
⇒
⇒ // Hamburger-Noether development of branch nr.3:
⇒ x = z(1)*y
⇒ y = -z(1)^2
⇒
L[2]; // number of branches in respective conjugacy classes
⇒ 2,1,1

```

See also: [Section D.6.15.2 \[develop\]](#), page 1726; [Section D.6.15.5 \[displayHNE\]](#), page 1730; [Section D.6.15.3 \[extdevelop\]](#), page 1727; [Section D.6.15.4 \[param\]](#), page 1728.

D.6.15.2 develop

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `develop(f [,n]);` f poly, n int

Assume: f is a bivariate polynomial (in the first 2 ring variables) and irreducible as power series (for reducible f use `hnexpansion`).

Return: list L with:

$L[1]$; matrix:

Each row contains the coefficients of the corresponding line of the Hamburger-Noether expansion (HNE). The end of the line is marked in the matrix by the first ring variable (usually x).

$L[2]$; intvec:

indicating the length of lines of the HNE

$L[3]$; int: 0 if the 1st ring variable was transversal (with respect to f),
 1 if the variables were changed at the beginning of the computation,
 -1 if an error has occurred.

$L[4]$; poly:

the transformed polynomial of f to make it possible to extend the Hamburger-Noether development a posteriori without having to do all the previous calculation once again (0 if not needed)

$L[5]$; int: 1 if the curve has exactly one branch (i.e., is irreducible),
 0 else (i.e., the curve has more than one HNE, or f is not valid).

Display: The (non zero) elements of the HNE (if not called by another proc).

Note: The optional parameter n affects only the computation of the LAST line of the HNE. If it is given, the HN-matrix $L[1]$ will have at least n columns.

Otherwise, the number of columns will be chosen minimal such that the matrix contains all necessary information (i.e., all lines of the HNE but the last (which is in general infinite) have place).

If n is negative, the algorithm is stopped as soon as the computed information is sufficient for `invariants(L)`, but the HN-matrix $L[1]$ may still contain undetermined elements, which are marked with the 2nd variable (of the basering).

For time critical computations it is recommended to use `ring ..., (x,y), ls` as basering - it increases the algorithm's speed.

If `printlevel >= 0` comments are displayed (default is `printlevel=0`).

Example:

```
LIB "hnoether.lib";
ring exring = 7, (x,y), ds;
list Hne=develop(4x98+2x49y7+x11y14+2y14);
print(Hne[1]);
⇒ 0,0, 0,0,0,0,3,x,
⇒ 0,x, 0,0,0,0,0,0,
⇒ 0,0, 0,x,0,0,0,0,
⇒ 0,x, 0,0,0,0,0,0,
⇒ 0,-1,0,0,0,0,0,0
// therefore the HNE is:
// z(-1)= 3*z(0)^7 + z(0)^7*z(1),
// z(0) = z(1)*z(2),          (there is 1 zero in the 2nd row before x)
// z(1) = z(2)^3*z(3),        (there are 3 zeroes in the 3rd row)
// z(2) = z(3)*z(4),
// z(3) = -z(4)^2 + 0*z(4)^3 + ... + 0*z(4)^8 + ?*z(4)^9 + ...
// (the missing x in the last line indicates that it is not complete.)
Hne[2];
⇒ 7,1,3,1,-1
param(Hne);
⇒ // ** Warning: result is exact up to order 20 in x and 104 in y !
⇒ _[1]=-x14
⇒ _[2]=-3x98-x109
// parametrization:  x(t)= -t^14+0(t^21),  y(t)= -3t^98+0(t^105)
// (the term -t^109 in y may have a wrong coefficient)
displayHNE(Hne);
⇒ y = 3*x^7+z(1)*x^7
⇒ x = z(1)*z(2)
⇒ z(1) = z(2)^3*z(3)
⇒ z(2) = z(3)*z(4)
⇒ z(3) = -z(4)^2 + ..... (terms of degree >=9)
```

See also: [Section D.6.15.5 \[displayHNE\], page 1730](#); [Section D.6.15.3 \[extdevelop\], page 1727](#); [Section D.6.15.1 \[hnexpansion\], page 1724](#).

D.6.15.3 extdevelop

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\], page 1723](#)).

Usage: `extdevelop(L,N);` list L, int N

Assume: L is the output of `develop(f)`, or of `extdevelop(l,n)`, or one entry in the list `hne` in the ring created by `hnexpansion(f[, "ess"])`.

Return: an extension of the Hamburger-Noether development of `f` as a list in the same format as L has (up to the last entry in the output of `develop(f)`).
Type `help develop;`, resp. `help hnexpansion;` for more details.

Note: The new HN-matrix will have at least N columns (if the HNE is not finite). In particular, if `f` is irreducible then (in most cases) `extdevelop(develop(f),N)` will produce the same result as `develop(f,N)`.
If the matrix M of L has n columns then, compared with `parametrization(L)`,

`parametrize(extdevelop(L,N))` will increase the exactness by at least $(N-n)$ more significant monomials.

Example:

```
LIB "hnoether.lib";
ring exring=0,(x,y),dp;
list Hne=hnexpansion(x14-3y2x11-y3x10-y2x9+3y4x8+y5x7+3y4x6+x5*(-y6+y5)
-3y6x3-y7x2+y8);
⇒ // No change of ring necessary, return value is HN expansion.
displayHNE(Hne);    // HNE of 1st,3rd branch is finite
⇒ // Hamburger-Noether development of branch nr.1:
⇒   y = z(1)*x
⇒   x = z(1)^2
⇒
⇒ // Hamburger-Noether development of branch nr.2:
⇒   y = z(1)*x
⇒   x = z(1)^2+z(1)^2*z(2)
⇒   z(1) = z(2)^2-z(2)^3 + ..... (terms of degree >=4)
⇒
⇒ // Hamburger-Noether development of branch nr.3:
⇒   y = z(1)*x^2
⇒   x = z(1)^2
⇒
print(extdevelop(Hne[1],5)[1]);
⇒ No extension is possible
⇒ 0,x,0,
⇒ 0,1,x
list ehne=extdevelop(Hne[2],5);
displayHNE(ehne);
⇒   y = z(1)*x
⇒   x = z(1)^2+z(1)^2*z(2)
⇒   z(1) = z(2)^2-z(2)^3+z(2)^4-z(2)^5 + ..... (terms of degree >=6)
param(Hne[2]);
⇒ // ** Warning: result is exact up to order 5 in x and 7 in y !
⇒ _[1]=x7-x6-x5+x4
⇒ _[2]=-x10+2x9-2x7+x6
param(ehne);
⇒ // ** Warning: result is exact up to order 7 in x and 9 in y !
⇒ _[1]=x11-x10+x9-x8-x7+x6-x5+x4
⇒ _[2]=-x16+2x15-3x14+4x13-2x12+2x10-4x9+3x8-2x7+x6
```

See also: [Section D.6.15.2 \[develop\]](#), page 1726; [Section D.6.15.1 \[hnexpansion\]](#), page 1724; [Section D.6.15.4 \[param\]](#), page 1728.

D.6.15.4 param

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `param(L [,s]);` L list, s any type (optional)

Assume: L is the output of `develop(f)`, or of `extdevelop(develop(f),n)`, or (one entry in) the list of HN data created by `hnexpansion(f[,"ess"])`.

Return: If L are the HN data of an irreducible plane curve singularity f: a parametrization for f in the following format:

- if only the list L is given, the result is an ideal of two polynomials $p[1], p[2]$: if the HNE was finite then $f(p[1], p[2])=0$; if not, the true parametrization will be given by two power series, and $p[1], p[2]$ are truncations of these series.

- if the optional parameter s is given, the result is a list l : $l[1]=\text{param}(L)$ (ideal) and $l[2]=\text{intvec}$ with two entries indicating the highest degree up to which the coefficients of the monomials in $l[1]$ are exact (entry -1 means that the corresponding parametrization is exact).

If L collects the HN data of a reducible plane curve singularity f , the return value is a list of parametrizations in the respective format.

Note: If the basering has only 2 variables, the first variable is chosen as indefinite. Otherwise, the 3rd variable is chosen.

Example:

```
LIB "hnoether.lib";
ring exring=0,(x,y,t),ds;
poly f=x3+2xy2+y2;
list Hne=develop(f);
list hne_extended=extdevelop(Hne,10);
// compare the HNE matrices ...
print(Hne[1]);
  => 0,x,
  => 0,-1
print(hne_extended[1]);
  => 0,x, 0,0,0,0, 0,0,0,0,
  => 0,-1,0,2,0,-4,0,8,0,-16
// ... and the resulting parametrizations:
param(Hne);
  => // ** Warning: result is exact up to order 2 in x and 3 in y !
  => _[1]=-t2
  => _[2]=-t3
param(hne_extended);
  => // ** Warning: result is exact up to order 10 in x and 11 in y !
  => _[1]=-t2+2t4-4t6+8t8-16t10
  => _[2]=-t3+2t5-4t7+8t9-16t11
param(hne_extended,0);
  => // ** Warning: result is exact up to order 10 in x and 11 in y !
  => [1]:
  =>   _[1]=-t2+2t4-4t6+8t8-16t10
  =>   _[2]=-t3+2t5-4t7+8t9-16t11
  => [2]:
  =>   10,11
// An example with more than one branch:
list L=hnexpansion(f*(x2+y4));
  =>
  => // 'hnexpansion' created a list of one ring.
  => // To see the ring and the data stored in the ring, type (if you assigned
  => // the name L to the list):
  =>   show(L);
  => // To display the computed HN expansion, type
  =>   def HNring = L[1]; setring HNring; displayHNE(hne);
def HNring = L[1]; setring HNring;
param(hne);
```

See also: [Section D.6.15.2 \[develop\]](#), page 1726; [Section D.6.15.3 \[extdevelop\]](#), page 1727.

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether_lib\]](#), page 1723).

See also: [Section D.6.15.2 \[develop\]](#), page 1726; [Section D.6.15.1 \[hnexpansion\]](#), page 1724.

D.6.15.6 invariants

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `invariants(INPUT)`; INPUT list or poly

Assume: INPUT is the output of `develop(f)`, or of `extdevelop(develop(f),n)`, or one entry of the list of HN data computed by `hnexpansion(f[, "ess"])`.

Return: list INV of the following format:

```
INV[1]: intvec    (characteristic exponents)
INV[2]: intvec    (generators of the semigroup)
INV[3]: intvec    (Puisseux pairs, 1st components)
INV[4]: intvec    (Puisseux pairs, 2nd components)
INV[5]: int       (degree of the conductor)
INV[6]: intvec    (sequence of multiplicities)
```

If INPUT contains no valid HN expansion, the empty list is returned.

Assume: INPUT is a bivariate polynomial `f`, or the output of `hnexpansion(f)`, or the list of HN data computed by `hnexpansion(f[, "ess"])`.

Return: list INV, such that `INV[i]` coincides with the output of `invariants(develop(f[i]))`, where `f[i]` is the *i*-th branch of `f`, and the last entry of INV contains further invariants of `f` in the format:

```
INV[last][1] : intmat    (contact matrix of the branches)
INV[last][2] : intmat    (intersection multiplicities of the branches)
INV[last][3] : int       (delta invariant of f)
```

Note: In case the Hamburger-Noether expansion of the curve `f` is needed for other purposes as well it is better to calculate this first with the aid of `hnexpansion` and use it as input instead of the polynomial itself.

Example:

```
LIB "hnoether.lib";
ring exring=0,(x,y),dp;
list Hne=develop(y4+2x3y2+x6+x5y);
list INV=invariants(Hne);
INV[1];                      // the characteristic exponents
⇨ 4,6,7
INV[2];                      // the generators of the semigroup of values
⇨ 4,6,13
INV[3],INV[4];              // the Puisseux pairs in packed form
⇨ 3,7 2,2
INV[5] div 2;              // the delta-invariant
⇨ 8
INV[6];                    // the sequence of multiplicities
⇨ 4,2,2,1,1
// To display the invariants more 'nicely':
displayInvariants(Hne);
⇨ characteristic exponents : 4,6,7
⇨ generators of semigroup : 4,6,13
⇨ Puisseux pairs : (3,2)(7,2)
⇨ degree of the conductor : 16
⇨ delta invariant : 8
⇨ sequence of multiplicities: 4,2,2,1,1
```

```

//////////
INV=invariants((x2-y3)*(x3-y5));
INV[1][1];           // the characteristic exponents of the first branch
↳ 2,3
INV[2][6];           // the sequence of multiplicities of the second branch
↳ 3,2,1,1
print(INV[size(INV)][1]);           // the contact matrix of the branches
↳      0      3
↳      3      0
print(INV[size(INV)][2]);           // the intersection numbers of the branches
↳      0      9
↳      9      0
INV[size(INV)][3];           // the delta invariant of the curve
↳ 14

```

See also: [Section D.6.15.2 \[develop\]](#), page 1726; [Section D.6.15.7 \[displayInvariants\]](#), page 1732; [Section D.6.15.1 \[hnexpansion\]](#), page 1724; [Section D.6.15.10 \[intersection\]](#), page 1735; [Section D.6.15.8 \[multsequence\]](#), page 1732.

D.6.15.7 displayInvariants

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `displayInvariants(INPUT)`; INPUT list or poly

Assume: INPUT is a bivariate polynomial, or the output of `develop(f)`, resp. of `extdevelop(develop(f),n)`, or (one entry of) the list of HN data computed by `hnexpansion(f, "ess")`.

Return: none

Display: invariants of the corresponding branch, resp. of all branches, in a better readable form.

Note: If the Hamburger-Noether expansion of the curve `f` is needed for other purposes as well it is better to calculate this first with the aid of `hnexpansion` and use it as input instead of the polynomial itself.

Example:

```

LIB "hnoether.lib";
ring exring=0,(x,y),dp;
list Hne=develop(y4+2x3y2+x6+x5y);
displayInvariants(Hne);
↳ characteristic exponents : 4,6,7
↳ generators of semigroup : 4,6,13
↳ Puiseux pairs : (3,2)(7,2)
↳ degree of the conductor : 16
↳ delta invariant : 8
↳ sequence of multiplicities: 4,2,2,1,1

```

See also: [Section D.6.15.2 \[develop\]](#), page 1726; [Section D.6.15.1 \[hnexpansion\]](#), page 1724; [Section D.6.15.10 \[intersection\]](#), page 1735; [Section D.6.15.6 \[invariants\]](#), page 1731.

D.6.15.8 multsequence

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `multsequence(INPUT)`; INPUT list or poly

- Assume:** INPUT is the output of `develop(f)`, or of `extdevelop(develop(f),n)`, or one entry of the list of HN data computed by `hnexpansion(f[, "ess"])`.
- Return:** intvec corresponding to the multiplicity sequence of the irreducible plane curve singularity described by the HN data (return value coincides with `invariants(INPUT) [6]`).
- Assume:** INPUT is a bivariate polynomial `f`, or the output of `hnexpansion(f)`, or the list of HN data computed by `hnexpansion(f[, "ess"])`.
- Return:** list of two integer matrices:
- `multsequence(INPUT) [1] [i, *]`
contains the multiplicities of the branches at their infinitely near point of 0 in its (i-1) order neighbourhood (i.e., i=1: multiplicity of the branches themselves, i=2: multiplicity of their 1st quadratic transform, etc.,
Hence, `multsequence(INPUT) [1] [*, j]` is the multiplicity sequence of branch j.
- `multsequence(INPUT) [2] [i, *]:`
contains the information which of these infinitely near points coincide.
- Note:** The order of the elements of the list of HN data obtained from `hnexpansion(f[, "ess"])` must not be changed (because otherwise the coincident infinitely near points couldn't be grouped together, see the meaning of the 2nd intmat in the example).
Hence, it is not wise to compute the HN expansion of polynomial factors separately, put them into a list INPUT and call `multsequence(INPUT)`.
Use `displayMultsequence` to produce a better readable output for reducible curves on the screen.
In case the Hamburger-Noether expansion of the curve `f` is needed for other purposes as well it is better to calculate this first with the aid of `hnexpansion` and use it as input instead of the polynomial itself.

Example:

```
LIB "hnoether.lib";
ring r=0,(x,y),dp;
list Hne=hnexpansion((x6-y10)*(x+y2-y3)*(x+y2+y3));
⇨ // No change of ring necessary, return value is HN expansion.
multsequence(Hne[1])," | ",multsequence(Hne[2])," | ",
multsequence(Hne[3])," | ",multsequence(Hne[4]);
⇨ 3,2,1,1 | 3,2,1,1 | 1 | 1
multsequence(Hne);
⇨ [1]:
⇨ 3,3,1,1,
⇨ 2,2,1,1,
⇨ 1,1,1,1,
⇨ 1,1,1,1,
⇨ 1,1,1,1
⇨ [2]:
⇨ 4,0,0,0,
⇨ 4,0,0,0,
⇨ 2,2,0,0,
⇨ 2,1,1,0,
⇨ 1,1,1,1
// The meaning of the entries of the 2nd matrix is as follows:
displayMultsequence(Hne);
```

```

⇒ [(3,3,1,1)],
⇒ [(2,2,1,1)],
⇒ [(1,1),(1,1)],
⇒ [(1,1),(1),(1)],
⇒ [(1),(1),(1),(1)]

```

See also: [Section D.6.15.2 \[develop\]](#), page 1726; [Section D.6.15.9 \[displayMultsequence\]](#), page 1734; [Section D.6.15.1 \[hnexpansion\]](#), page 1724; [Section D.6.15.17 \[separateHNE\]](#), page 1738.

D.6.15.9 displayMultsequence

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `displayMultsequence(INPUT)`; INPUT list or poly

Assume: INPUT is a bivariate polynomial, or the output of `develop(f)`, resp. of `extdevelop(develop(f),n)`, or (one entry of) the list of HN data computed by `hnexpansion(f[,"ess"])`, or the output of `hnexpansion(f)`.

Return: nothing

Display: the sequence of multiplicities:

```

- if INPUT=develop(f) or INPUT=extdevelop(develop(f),n) or INPUT=hne[i]:
    a , b , c , ..... , 1
- if INPUT=f or INPUT=hnexpansion(f) or INPUT=hne:
    [(a_1, .... , b_1 , .... , c_1)],
    [(a_2, ... ), ... , (... , c_2)],
    ..... ,
    [(a_n),(b_n), ..... , (c_n)]
with:
    a_1 , ... , a_n the sequence of multiplicities of the 1st branch,
    [...] the multiplicities of the j-th transform of all branches,
    (...) indicating branches meeting in an infinitely near point.

```

Note: The Same restrictions as in `multsequence` apply for the input.
In case the Hamburger-Noether expansion of the curve `f` is needed for other purposes as well it is better to calculate this first with the aid of `hnexpansion` and use it as input instead of the polynomial itself.

Example:

```

LIB "hnoether.lib";
ring r=0,(x,y),dp;
// Example 1: Input = output of develop
displayMultsequence(develop(x3-y5));
⇒ The sequence of multiplicities is 3,2,1,1
// Example 2: Input = bivariate polynomial
displayMultsequence((x6-y10)*(x+y2-y3)*(x+y2+y3));
⇒ [(3,3,1,1)],
⇒ [(2,2,1,1)],
⇒ [(1,1),(1,1)],
⇒ [(1,1),(1),(1)],
⇒ [(1),(1),(1),(1)]

```

See also: [Section D.6.15.2 \[develop\]](#), page 1726; [Section D.6.15.1 \[hnexpansion\]](#), page 1724; [Section D.6.15.8 \[multsequence\]](#), page 1732; [Section D.6.15.17 \[separateHNE\]](#), page 1738.

D.6.15.10 intersection

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `intersection(hne1,hne2);` hne1, hne2 lists

Assume: `hne1`, `hne2` represent an HN expansion of an irreducible plane curve singularity (that is, are the output of `develop(f)`, or of `extdevelop(develop(f),n)`, or one entry of the list of HN data computed by `hnexpansion(f[,"ess"])`).

Return: `int`, the intersection multiplicity of the irreducible plane curve singularities corresponding to `hne1` and `hne2`.

Example:

```
LIB "hnoether.lib";
ring r=0,(x,y),dp;
list Hne=hnexpansion((x2-y3)*(x2+y3));
⇒ // No change of ring necessary, return value is HN expansion.
intersection(Hne[1],Hne[2]);
⇒ 6
```

See also: [Section D.6.15.7 \[displayInvariants\]](#), page 1732; [Section D.6.15.1 \[hnexpansion\]](#), page 1724.

D.6.15.11 is_irred

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `is_irred(f);` `f` poly

Assume: `f` is a squarefree bivariate polynomial (in the first 2 ring variables).

Return: `int` (0 or 1):
 - `is_irred(f)=1` if `f` is irreducible as a formal power series over the algebraic closure of its coefficient field (`f` defines an analytically irreducible curve at zero),
 - `is_irred(f)=0` otherwise.

Note: 0 and units in the ring of formal power series are considered to be not irreducible.

Example:

```
LIB "hnoether.lib";
ring exring=0,(x,y),ls;
is_irred(x2+y3);
⇒ 1
is_irred(x2+y2);
⇒ 0
is_irred(x2+y3+1);
⇒ 0
```

D.6.15.12 delta

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `delta(INPUT);` `INPUT` a polynomial defining an isolated plane curve singularity at 0, or the Hamburger-Noether expansion thereof, i.e. the output of `develop(f)`, or the output of `hnexpansion(f)`, or the list of HN data computed by `hnexpansion(f)`.

Return: `int`, the delta invariant of the singularity at 0, that is, the vector space dimension of \tilde{R}/R , (\tilde{R} the normalization of the local ring of the singularity).

Note: In case the Hamburger-Noether expansion of the curve f is needed for other purposes as well it is better to calculate this first with the aid of `hnexpansion` and use it as input instead of the polynomial itself.

Example:

```
LIB "hnoether.lib";
ring r = 32003, (x,y), ds;
poly f = x25+x24-4x23-1x22y+4x22+8x21y-2x21-12x20y-4x19y2+4x20+10x19y
+12x18y2-24x18y-20x17y2-4x16y3+x18+60x16y2+20x15y3-9x16y
-80x14y3-10x13y4+36x14y2+60x12y4+2x11y5-84x12y3-24x10y5
+126x10y4+4x8y6-126x8y5+84x6y6-36x4y7+9x2y8-1y9;
delta(f);
⇒ 96
```

See also: [Section D.4.23.11 \[deltaLoc\]](#), page 1207; [Section D.6.15.6 \[invariants\]](#), page 1731.

D.6.15.13 newtonpoly

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `newtonpoly(f); f poly`

Assume: basering has exactly two variables;
 f is convenient, that is, $f(x,0) \neq 0 \neq f(0,y)$.

Return: list of intvecs (= coordinates x,y of the Newton polygon of f).

Note: Procedure uses `execute`; this can be avoided by calling `newtonpoly(f,1)` if the ordering of the basering is `ls`.

Example:

```
LIB "hnoether.lib";
ring r=0, (x,y), ls;
poly f=x5+2x3y-x2y2+3xy5+y6-y7;
newtonpoly(f);
⇒ [1]:
⇒ 0,6
⇒ [2]:
⇒ 2,2
⇒ [3]:
⇒ 3,1
⇒ [4]:
⇒ 5,0
```

D.6.15.14 is_NND

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `is_NND(f[,mu,NP]); f poly, mu int, NP list of intvecs`

Assume: f is convenient, that is, $f(x,0) \neq 0 \neq f(0,y)$;
 μ (optional) is Milnor number of f .
 NP (optional) is output of `newtonpoly(f)`.

Return: int: 1 if f is Newton non-degenerate, 0 otherwise.

Example:

```

LIB "hnoether.lib";
ring r=0,(x,y),ls;
poly f=x5+y3;
is_NND(f);
↳ 1
poly g=(x-y)^5+3xy5+y6-y7;
is_NND(g);
↳ 0
// if already computed, one should give the Minor number and Newton polygon
// as second and third input:
int mu=milnor(g);
list NP=newtonpoly(g);
is_NND(g,mu,NP);
↳ 0

```

See also: [Section D.6.15.13 \[newtonpoly\]](#), page 1736.

D.6.15.15 stripHNE

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: stripHNE(L); L list

Assume: L is the output of `develop(f)`, or of `extdevelop(develop(f),n)`, or (one entry of) the list `hne` in the ring created by `hnexpansion(f, "ess")`.

Return: list in the same format as L, but all polynomials `L[4]`, resp. `L[i][4]`, are set to zero.

Note: The purpose of this procedure is to remove huge amounts of data no longer needed. It is useful, if one or more of the polynomials in L consume much memory. It is still possible to compute invariants, parametrizations etc. with the stripped HNE(s), but it is not possible to use `extdevelop` with them.

Example:

```

LIB "hnoether.lib";
ring r=0,(x,y),dp;
list Hne=develop(x2+y3+y4);
Hne;
↳ [1]:
↳   _[1,1]=0
↳   _[1,2]=x
↳   _[2,1]=0
↳   _[2,2]=-1
↳ [2]:
↳   1,-1
↳ [3]:
↳   1
↳ [4]:
↳   x4-2x2y+y2+y
↳ [5]:
↳   1
stripHNE(Hne);
↳ [1]:
↳   _[1,1]=0
↳   _[1,2]=x
↳   _[2,1]=0

```

```

↳      _[2,2]==-1
↳ [2]:
↳      1,-1
↳ [3]:
↳      1
↳ [4]:
↳      0
↳ [5]:
↳      1

```

See also: [Section D.6.15.2 \[develop\]](#), page 1726; [Section D.6.15.3 \[extdevelop\]](#), page 1727; [Section D.6.15.1 \[hnexpansion\]](#), page 1724.

D.6.15.16 `puiseux2generators`

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `puiseux2generators(m,n)`; `m,n` intvec

Assume: `m`, resp. `n`, represent the 1st, resp. 2nd, components of Puiseux pairs (e.g., `m=invariants(L)[3]`, `n=invariants(L)[4]`).

Return: intvec of the generators of the semigroup of values.

Example:

```

LIB "hnoether.lib";
// take (3,2),(7,2),(15,2),(31,2),(63,2),(127,2) as Puiseux pairs:
puiseux2generators(intvec(3,7,15,31,63,127),intvec(2,2,2,2,2,2));
↳ 64,96,208,424,852,1706,3413

```

See also: [Section D.6.15.6 \[invariants\]](#), page 1731.

D.6.15.17 `separateHNE`

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `separateHNE(hne1,hne2)`; `hne1`, `hne2` lists

Assume: `hne1`, `hne2` are HNEs (=output of `develop(f)`, `extdevelop(develop(f),n)`, or one entry in the list `hne` in the ring created by `hnexpansion(f[,"ess"])`).

Return: number of quadratic transformations needed to separate both curves (branches).

Example:

```

LIB "hnoether.lib";
int p=printlevel; printlevel=-1;
ring r=0,(x,y),dp;
list hne1=develop(x);
list hne2=develop(x+y);
list hne3=develop(x+y^2);
separateHNE(hne1,hne2); // two transversal lines
↳ 1
separateHNE(hne1,hne3); // one quadratic transform. gives 1st example
↳ 2
printlevel=p;

```

See also: [Section D.6.15.2 \[develop\]](#), page 1726; [Section D.6.15.9 \[displayMultsequence\]](#), page 1734; [Section D.6.15.1 \[hnexpansion\]](#), page 1724; [Section D.6.15.8 \[multsequence\]](#), page 1732.

D.6.15.18 squarefree

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `squarefree(f); f poly`

Assume: `f` is a bivariate polynomial (in the first 2 ring variables).

Return: `poly`, a squarefree divisor of `f`.

Note: Usually, the return value is the greatest squarefree divisor, but there is one exception: factors with a p -th root, p the characteristic of the basering, are lost.

Example:

```
LIB "hnoether.lib";
ring exring=3,(x,y),dp;
squarefree((x3+y)^2);
  ↳ x3+y
squarefree((x+y)^3*(x-y)^2); // Warning: (x+y)^3 is lost
  ↳ x-y
squarefree((x+y)^4*(x-y)^2); // result is (x+y)*(x-y)
  ↳ x2-y2
```

See also: [Section D.6.15.19 \[allsquarefree\]](#), page 1739.

D.6.15.19 allsquarefree

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage : `allsquarefree(f,g); f,g poly`

Assume: `g` is the output of `squarefree(f)`.

Return: the greatest squarefree divisor of `f`.

Note : This proc uses `factorize` to get the missing factors of `f` not in `g` and, therefore, may be slow.

Example:

```
LIB "hnoether.lib";
ring exring=7,(x,y),dp;
poly f=(x+y)^7*(x-y)^8;
poly g=squarefree(f);
g; // factor x+y lost, since characteristic=7
  ↳ x-y
allsquarefree(f,g); // all factors (x+y)*(x-y) found
  ↳ x2-y2
```

See also: [Section D.6.15.18 \[squarefree\]](#), page 1739.

D.6.15.20 further_hn_proc

Procedure from library `hnoether.lib` (see [Section D.6.15 \[hnoether.lib\]](#), page 1723).

Usage: `further_hn_proc();`

Note: The library `hnoether.lib` contains some more procedures which are not shown when typing `help hnoether.lib;`. They may be useful for interactive use (e.g. if you want to do the calculation of an HN development "by hand" to see the intermediate results), and they can be enumerated by calling `further_hn_proc()`.
Use `help <procedure>;` for detailed information about each of them.

Example:

```

LIB "hnoether.lib";
further_hn_proc();
⇒
⇒ The following procedures are also part of 'hnoether.lib':
⇒
⇒ getnm(f);           intersection pts. of Newton polygon with axes
⇒ T_Transform(f,Q,N); returns f(y,xy^Q)/y^NQ (f: poly, Q,N: int)
⇒ T1_Transform(f,d,M); returns f(x,y+d*x^M) (f: poly,d:number,M:int)
⇒ T2_Transform(f,d,M,N,ref); a composition of T1 & T
⇒ koeff(f,I,J);       gets coefficient of indicated monomial of polynomial\
f
⇒ redleit(f,S,E);     restriction of monomials of f to line (S-E)
⇒ leit(f,n,m);        special case of redleit (for irred. polynomials)
⇒ testreducible(f,n,m); tests whether f is reducible
⇒ charPoly(f,M,N);    characteristic polynomial of f
⇒ find_in_list(L,p);  find int p in list L
⇒ get_last_divisor(M,N); last divisor in Euclid's algorithm
⇒ factorfirst(f,M,N); try to factor f without 'factorize'
⇒ factorlist(L);      factorize a list L of polynomials
⇒ referencepoly(D);   a polynomial f s.t. D is the Newton diagram of f

```

D.6.16 kskernel.lib**Library:** kskernel.lib**Purpose:** procedures for computing the kernel of the kodaira-spencer map**Author:** Tetyana Povalyaeva, povalya@mathematik.uni-kl.de**Procedures:****D.6.16.1 KSkker**Procedure from library kskernel.lib (see [Section D.6.16 \[kskernel.lib\]](#), page 1740).**Usage:** KSkker(int p,q); p,q relatively prime integers

Return: nothing; exports ring KSring, matrix KSkkernel and list 'weights'; KSkkernel is a matrix of coefficients of the generators of the kernel of Kodaira-Spencer map, 'weights' is a list of degrees for variables T

Example:

```

LIB "kskernel.lib";
int p=6;
int q=7;
KSkker(p,q);
setring Kskkernel::KSring;
print(KSkkernel);
⇒ 0,      0,      0,      0,      0,      2*T(1),
⇒ 0,      0,      0,      0,      0,      3*T(2),
⇒ 0,      0,      0,      0,      0,      4*T(3),
⇒ 0,      0,      0,      2*T(1),  3*T(2),  9*T(4),
⇒ 0,      0,      0,      3*T(2),  KSkkernel[5,5],10*T(5),
⇒ 2*T(1),3*T(2),KSkkernel[6,3],KSkkernel[6,4],KSkkernel[6,5],16*T(6)

```

D.6.16.2 KSconvert

Procedure from library `kskernel.lib` (see [Section D.6.16 \[kskernel.lib\]](#), page 1740).

Usage: `KSconvert(matrix M);`
 M is a matrix of coefficients of the generators of the kernel of Kodaira-Spencer map in variables $T(i)$ from the basering. To be called after the procedure `KSkker(p,q)`

Return: nothing; exports ring `KSring2` and matrix `KSkkernel2` within it, such that `KSring2` resp. `KSkkernel2` are in variables $T(w)$ with weights $-w$. These weights are computed in the procedure `KSkker(p,q)`

Example:

```
LIB "kskernel.lib";
int p=6;
int q=7;
KSkker(p,q);
setring Kskkernel::KSring;
KSconvert(KSkkernel);
⇒ // ** 'KSring2' is already global
setring Kskkernel::KSring2;
print(KSkkernel2);
⇒ 0,      0,      0,      0,      0,      2*T(2),
⇒ 0,      0,      0,      0,      0,      3*T(3),
⇒ 0,      0,      0,      0,      0,      4*T(4),
⇒ 0,      0,      0,      2*T(2),  3*T(3),  9*T(9),
⇒ 0,      0,      0,      3*T(3),  KSkernel2[5,5], 10*T(10),
⇒ 2*T(2), 3*T(3), KSkernel2[6,3], KSkernel2[6,4], KSkernel2[6,5], 16*T(16)
```

D.6.16.3 KSlinear

Procedure from library `kskernel.lib` (see [Section D.6.16 \[kskernel.lib\]](#), page 1740).

Usage: `KSlinear(matrix M);`
computes matrix of linear terms of the kernel of the Kodaira-Spencer map. To be called after the procedure `KSkker(p,q)`

Return: nothing; but replaces elements of the matrix `KSkkernel` in the ring `KSring` with their leading monomials w.r.t. the local ordering (ls)

Example:

```
LIB "kskernel.lib";
int p=6;
int q=7;
KSkker(p,q);
setring Kskkernel::KSring;
KSlinear(KSkkernel);
print(KSkkernel);
⇒ 0,      0,      0,      0,      0,      2*T(1),
⇒ 0,      0,      0,      0,      0,      3*T(2),
```

```

⇒ 0,      0,      0,      0,      0,      4*T(3),
⇒ 0,      0,      0,      2*T(1),3*T(2), 9*T(4),
⇒ 0,      0,      0,      3*T(2),4*T(3), 10*T(5),
⇒ 2*T(1),3*T(2),4*T(3),9*T(4),10*T(5),16*T(6)

```

D.6.16.4 KScoef

Procedure from library `kskernel.lib` (see [Section D.6.16 \[kskernel.lib\]](#), page 1740).

Return: exports ring `RC` and number `C` within it. `C` is the coefficient of the word defined in the list `qq`, being a part of $C[i,j]$ for x^p+y^q

Example:

```

LIB "kskernel.lib";
int p=5; int q=14;
int i=2; int j=9;
list L;
ring r=0,x,dp;
number c;
L[1]=3; L[2]=1; L[3]=3; L[4]=2;
KScoef(i,j,p,q,L);
c=imap(RC,C);
c;
⇒ 27/8575
L[1]=3; L[2]=1; L[3]=2; L[4]=3;
KScoef(i,j,p,q,L);
⇒ // ** redefining S ( export S;)
⇒ // ** redefining u ( export u;)
⇒ // ** redefining l ( export l;)
⇒ // ** redefining RC ( export RC;exportto(Top,RC);)
c=c+imap(RC,C);
c; // it is a coefficient of T1*T2*T3^2 in C[2,9] for x^5+y^14
⇒ 99/8575

```

D.6.16.5 StringF

Procedure from library `kskernel.lib` (see [Section D.6.16 \[kskernel.lib\]](#), page 1740).

Usage: `StringF(int i,j,p,q);`

Return: nothing; exports string `F` which contains an expression in variables $T(i)$ with non-resolved brackets

Example:

```

LIB "kskernel.lib";
int p=5; int q=14;
int i=2; int j=9;
StringF(i,j,p,q);
F;
⇒ T(7)+T(3)*(T(4)*(T(1))+T(1)*(T(4)+T(3)*(T(2))+T(2)*(T(3)+T(1)*(T(1))))))

```

D.6.17 mondromy_lib

Library: `mondromy.lib`

Purpose: Monodromy of an Isolated Hypersurface Singularity

Author: Mathias Schulze, email: mschulze@mathematik.uni-kl.de

Overview: A library to compute the monodromy of an isolated hypersurface singularity. It uses an algorithm by Brieskorn (manuscripta math. 2 (1970), 103-161) to compute a connection matrix of the meromorphic Gauss-Manin connection up to arbitrarily high order, and an algorithm of Gerard and Levelt (Ann. Inst. Fourier, Grenoble 23,1 (1973), pp. 157-195) to transform it to a simple pole.

Procedures: See also: [Section D.6.14 \[gmspoly_lib\], page 1722](#); [Section D.6.13 \[gmssing_lib\], page 1707](#).

D.6.17.1 detadj

Procedure from library `mondromy.lib` (see [Section D.6.17 \[mondromy_lib\], page 1742](#)).

Usage: `detadj(U)`; U matrix

Assume: U is a square matrix with non zero determinant.

Return: The procedure returns a list with at most 2 entries.
If U is not a square matrix, the list is empty.
If U is a square matrix, then the first entry is the determinant of U. If U is a square matrix and the determinant of U not zero, then the second entry is the adjoint matrix of U.

Display: The procedure displays comments if `printlevel` ≥ 1 .

Example:

```
LIB "mondromy.lib";
ring R=0,x,dp;
matrix U[2][2]=1,1+x,1+x2,1+x3;
list daU=detadj(U);
daU[1];
 $\mapsto -x^2-x$ 
print(daU[2]);
 $\mapsto x^3+1, -x-1,$ 
 $\mapsto -x^2-1, 1$ 
```

D.6.17.2 invunit

Procedure from library `mondromy.lib` (see [Section D.6.17 \[mondromy_lib\], page 1742](#)).

Usage: `invunit(u,n)`; u poly, n int

Assume: The polynomial u is a series unit.

Return: The procedure returns the series inverse of u up to order n or a zero polynomial if u is no series unit.

Display: The procedure displays comments if `printlevel` ≥ 1 .

Example:

```
LIB "mondromy.lib";
ring R=0,(x,y),dp;
invunit(2+x3+xy4,10);
 $\mapsto 1/8x^2y^8-1/16x^9+1/4x^4y^4+1/8x^6-1/4xy^4-1/4x^3+1/2$ 
```

D.6.17.3 jacoblift

Procedure from library `mondromy.lib` (see [Section D.6.17 \[mondromy.lib\]](#), page 1742).

Usage: `jacoblift(f); f poly`

Assume: The polynomial f in a series ring (local ordering) defines an isolated hypersurface singularity.

Return: The procedure returns a list with entries κ , ξ , u of type `int`, `vector`, `poly` such that κ is minimal with f^κ in `jacob(f)`, u is a unit, and $u \cdot f^\kappa = (\text{matrix}(\text{jacob}(f)) \cdot \xi)[1,1]$.

Display: The procedure displays comments if `printlevel` ≥ 1 .

Example:

```
LIB "mondromy.lib";
ring R=0,(x,y),ds;
poly f=x2y2+x6+y6;
jacoblift(f);
⇒ [1]:
⇒ 2
⇒ [2]:
⇒ 1/2x2y3*gen(2)+1/6x7*gen(1)+5/6x6y*gen(2)-2/3xy6*gen(1)+1/6y7*gen(2)-4\
x4y5*gen(2)-3/2x9y2*gen(1)-15/2x8y3*gen(2)+9/2x3y8*gen(1)-3/2x2y9*gen(2)
⇒ [3]:
⇒ 1-9x2y2
```

D.6.17.4 monodromyB

Procedure from library `mondromy.lib` (see [Section D.6.17 \[mondromy.lib\]](#), page 1742).

Usage: `monodromyB(f[,opt]); f poly, opt int`

Assume: The polynomial f in a series ring (local ordering) defines an isolated hypersurface singularity.

Return: The procedure returns a residue matrix M of the meromorphic Gauss-Manin connection of the singularity defined by f or an empty matrix if the assumptions are not fulfilled. If `opt`=0 (default), $\exp(-2\pi i M)$ is a monodromy matrix of f , else, only the characteristic polynomial of $\exp(-2\pi i M)$ coincides with the characteristic polynomial of the monodromy of f .

Display: The procedure displays more comments for higher `printlevel`.

Example:

```
LIB "mondromy.lib";
ring R=0,(x,y),ds;
poly f=x2y2+x6+y6;
matrix M=monodromyB(f);
print(M);
⇒ 7/6,0, 0,0, 0, 0,0, 0,-1/2,0, 0, 0, 0,
⇒ 0, 7/6,0,0, 0, 0,-1/2,0,0, 0, 0, 0, 0,
⇒ 0, 0, 1,0, 0, 0,0, 0,0, 0, 0, 0, 0,

D.6.17.5 H2basis

Procedure from library `mondromy.lib` (see [Section D.6.17 \[mondromy.lib\]](#), page 1742).

Usage: H2basis(f); f poly

Assume: The polynomial f in a series ring (local ordering) defines an isolated hypersurface singularity.

Return: The procedure returns a list of representatives of a $C\{f}$ -basis of the Brieskorn lattice $H'' = \Omega^{n+1}/df \wedge d\Omega^{n-1}$.

Theory: H'' is a free $C\{f}$ -module of rank $\text{milnor}(f)$.

Display: The procedure displays more comments for higher `printlevel`.

Example:

```

LIB "mondromy.lib";
ring R=0,(x,y),ds;
poly f=x2y2+x6+y6;
H2basis(f);
⇒ [1]:
⇒ x4
⇒ [2]:
⇒ x2y2
⇒ [3]:

⇒ 1

```

D.6.18 qhmoduli.lib

Library: qhmoduli.lib

Purpose: Moduli Spaces of Semi-Quasihomogeneous Singularities

Author: Thomas Bayer, email: bayert@in.tum.de

Procedures:

D.6.18.1 ArnoldAction

Procedure from library `qhmoduli.lib` (see [Section D.6.18 \[qhmoduli.lib\], page 1746](#)).

Usage: `ArnoldAction(f, [Gf, B]);` poly `f`; list `Gf, B`;
'`Gf`' is a list of two rings (coming from '`StabEqn`')

Purpose: compute the induced action of the stabilizer `G` of `f` on `T_`, where `T_` is given by the upper monomials `B` of the Milnor algebra of `f`.

Assume: `f` is quasihomogeneous

Return: polynomial ring over the same ground field, containing the ideals '`actionid`' and '`stabid`'.
- '`actionid`' is the ideal defining the induced action of `Gf` on `T_`
- '`stabid`' is the ideal of the stabilizer `Gf` in the new ring

Example:

```
LIB "qhmoduli.lib";
ring B = 0,(x,y,z), ls;
poly f = -z5+y5+x2z+x2y;
def R = ArnoldAction(f);
⇒ // ** redefining zz (int zz = 1;) qhmoduli.lib::StabEqnId:629
setring R;
actionid;
⇒ actionid[1]=-s(2)*t(1)+s(3)*t(1)
⇒ actionid[2]=-s(2)^2*t(2)+2*s(2)^2*t(3)^2+s(3)^2*t(2)
⇒ actionid[3]=s(2)*t(3)+s(3)*t(3)
stabid;
⇒ stabid[1]=s(2)*s(3)
⇒ stabid[2]=s(1)^2*s(2)+s(1)^2*s(3)-1
⇒ stabid[3]=s(1)^2*s(3)^2-s(3)
⇒ stabid[4]=s(1)^2+s(2)^4-s(3)^4
⇒ stabid[5]=s(1)^4+s(2)^3-s(3)^3
⇒ stabid[6]=-s(1)^2*s(3)+s(3)^5
```

D.6.18.2 ModEqn

Procedure from library `qhmoduli.lib` (see [Section D.6.18 \[qhmoduli.lib\], page 1746](#)).

Usage: `ModEqn(f [, opt]);` poly `f`; int `opt`;

Purpose: compute equations of the moduli space of semiquasihomogenous hypersurface singularity with principal part `f` w.r.t. right equivalence

Assume: `f` quasihomogeneous polynomial with an isolated singularity at 0

- Return:** polynomial ring, possibly a simple extension of the ground field of the basering, containing the ideal 'modid'
 - 'modid' is the ideal of the moduli space if opt is even (> 0). otherwise it contains generators of the coordinate ring R of the moduli space (note : $\text{Spec}(R)$ is the moduli space)
- Options:** 1 compute equations of the mod. space,
 2 use a primary decomposition,
 4 compute E_{f0} , i.e., the image of G_{f0} ,
 to combine options, add their value, default: opt =7

Example:

```
LIB "qhmoduli.lib";
ring B = 0,(x,y), ls;
poly f = -x4 + xy5;
def R = ModEqn(f);
↪ // ** redefining zz (int zz = 1;) qhmoduli.lib::StabEqnId:629
setring R;
modid;
↪ modid[1]=Y(5)^2-Y(4)*Y(6)
↪ modid[2]=Y(4)*Y(5)-Y(3)*Y(6)
↪ modid[3]=Y(3)*Y(5)-Y(2)*Y(6)
↪ modid[4]=Y(2)*Y(5)-Y(1)*Y(6)
↪ modid[5]=Y(4)^2-Y(3)*Y(5)
↪ modid[6]=Y(3)*Y(4)-Y(2)*Y(5)
↪ modid[7]=Y(2)*Y(4)-Y(1)*Y(5)
↪ modid[8]=Y(3)^2-Y(2)*Y(4)
↪ modid[9]=Y(2)*Y(3)-Y(1)*Y(4)
↪ modid[10]=Y(2)^2-Y(1)*Y(3)
```

D.6.18.3 QuotientEquations

Procedure from library `qhmoduli.lib` (see [Section D.6.18 \[qhmoduli.lib\]](#), page 1746).

- Usage:** QuotientEquations(G,action,emb [, opt]); ideal G,action,emb;int opt
- Purpose:** compute the quotient of the variety given by the parameterization 'emb' by the linear action 'action' of the algebraic group G.
- Assume:** 'action' is linear, G must be finite if the Reynolds operator is needed (i.e., $\text{NullCone}(G,\text{action})$ returns some non-invariant polys)
- Return:** polynomial ring over a simple extension of the ground field of the basering, containing the ideals 'id' and 'embedid'.
 - 'id' contains the equations of the quotient, if opt = 1; if opt = 0, 2, 'id' contains generators of the coordinate ring R of the quotient ($\text{Spec}(R)$ is the quotient)
 - 'embedid' = 0, if opt = 1;
 if opt = 0, 2, it is the ideal defining the equivariant embedding
- Options:** 1 compute equations of the quotient,
 2 use a primary decomposition when computing the Reynolds operator,
 to combine options, add their value, default: opt =3.

D.6.18.4 StabEqn

Procedure from library `qhmoduli.lib` (see [Section D.6.18 \[qhmoduli.lib\]](#), page 1746).

Usage: `StabEqn(f); f polynomial`

Purpose: compute the equations of the isometry group of f .

Assume: f semiquasihomogeneous polynomial with an isolated singularity at 0

Return: list of two rings 'S1', 'S2'
 - 'S1' contains the equations of the stabilizer (ideal 'stabid')
 - 'S2' contains the action of the stabilizer (ideal 'actionid')

Global: `varSubsList`, contains the index j s.t. $x(i) \rightarrow x(i)t(j) \dots$

Example:

```
LIB "qhmoduli.lib";
ring B = 0,(x,y,z), ls;
poly f = -z5+y5+x2z+x2y;
list stab = StabEqn(f);
⇒ // ** redefining zz (int zz = 1;) qhmoduli.lib::StabEqnId:629
def S1 = stab[1]; setring S1; stabid;
⇒ stabid[1]=s(2)*s(3)
⇒ stabid[2]=s(1)^2*s(2)+s(1)^2*s(3)-1
⇒ stabid[3]=s(1)^2*s(3)^2-s(3)
⇒ stabid[4]=s(2)^4-s(3)^4+s(1)^2
⇒ stabid[5]=s(1)^4+s(2)^3-s(3)^3
⇒ stabid[6]=s(3)^5-s(1)^2*s(3)
def S2 = stab[2]; setring S2; actionid;
⇒ actionid[1]=s(1)*x
⇒ actionid[2]=s(3)*y+s(2)*z
⇒ actionid[3]=s(2)*y+s(3)*z
```

D.6.18.5 StabEqnId

Procedure from library `qhmoduli.lib` (see [Section D.6.18 \[qhmoduli.lib\]](#), page 1746).

Usage: `StabEqnId(I, w); I ideal, w intvec`

Purpose: compute the equations of the isometry group of the ideal I , each generator of I is fixed by the stabilizer.

Assume: I semiquasihomogeneous ideal w.r.t. 'w' with an isolated singularity at 0

Return: list of two rings 'S1', 'S2'
 - 'S1' contains the equations of the stabilizer (ideal 'stabid')
 - 'S2' contains the action of the stabilizer (ideal 'actionid')

Global: `varSubsList`, contains the index j s.t. $t(i) \rightarrow t(i)t(j) \dots$

Example:

```
LIB "qhmoduli.lib";
ring B = 0,(x,y,z), ls;
ideal I = x2,y3,z6;
intvec w = 3,2,1;
list stab = StabEqnId(I, w);
⇒ // ** redefining zz (int zz = 1;) qhmoduli.lib::StabEqnId:629
def S1 = stab[1]; setring S1; stabid;
⇒ stabid[1]=s(1)^2-1
⇒ stabid[2]=s(2)^3-1
⇒ stabid[3]=s(3)^6-1
```

```

def S2 = stab[2]; setring S2; actionid;
  ↪ actionid[1]=s(1)*x
  ↪ actionid[2]=s(2)*y
  ↪ actionid[3]=s(3)*z

```

D.6.18.6 StabOrder

Procedure from library `qhmoduli.lib` (see [Section D.6.18 \[qhmoduli.lib\]](#), page 1746).

Usage: `StabOrder(f); poly f`

Purpose: compute the order of the stabilizer group of `f`.

Assume: `f` quasihomogeneous polynomial with an isolated singularity at 0

Return: `int`

Global: `varSubsList`

D.6.18.7 UpperMonomials

Procedure from library `qhmoduli.lib` (see [Section D.6.18 \[qhmoduli.lib\]](#), page 1746).

Usage: `UpperMonomials(poly f, [intvec w])`

Purpose: compute the upper monomials of the milnor algebra of `f`.

Assume: `f` is quasihomogeneous (w.r.t. `w`)

Return: `ideal`

Example:

```

LIB "qhmoduli.lib";
ring B = 0,(x,y,z), ls;
poly f = -z5+y5+x2z+x2y;
UpperMonomials(f);
  ↪ _[1]=y3z3
  ↪ _[2]=x2y3
  ↪ _[3]=x2y2

```

D.6.18.8 Max

Procedure from library `qhmoduli.lib` (see [Section D.6.18 \[qhmoduli.lib\]](#), page 1746).

Usage: `Max(data); intvec/list of integers`

Purpose: find the maximal integer contained in 'data'

Return: `list`

Assume: ' data ' contains only integers and is not empty

Example:

```

LIB "qhmoduli.lib";
Max(list(1,2,3));
  ↪ 3

```

D.6.18.9 Min

Procedure from library `qhmoduli.lib` (see [Section D.6.18 \[qhmoduli.lib\]](#), page 1746).

Usage: `Min(data);` intvec/list of integers

Purpose: find the minimal integer contained in 'data'

Return: list

Assume: 'data' contains only integers and is not empty

Example:

```
LIB "qhmoduli.lib";
Min(intvec(1,2,3));
↦ 1
```

D.6.19 realclassify.lib

Library: `realclassify.lib`

Purpose: Classification of real singularities

Author: Janko Boehm, boehm@mathematik.uni-kl.de
 Magdaleen Marais, magdaleen@aims.ac.za
 Andreas Steenpass, steenpass@mathematik.uni-kl.de

Overview: A library for classifying isolated hypersurface singularities over the reals w.r.t. right equivalence, based on the determinant of singularities by V.I. Arnold. This library is based on `classify2.lib` by the first and second author and G. Pfister, but handles the real case, while `classify2.lib` does the complex classification.

Procedures:

D.6.19.1 realclassify

Procedure from library `realclassify.lib` (see [Section D.6.19 \[realclassify.lib\]](#), page 1750).

Usage: `realclassify(f); f poly`

Return: A list of elements NF of type NormalFormEquation with the following keys:
 NF.singularityType = the type of the singularity as a string
 NF.normalFormEquation = an element F of type Poly with the normal form equation (a representative of the stable equivalence class of f, as chosen by Arnold)
 NF.modality = the modality of f
 NF.parameters = a list where each entry is a list consisting out of the parameter term in the normalform equation and an interval
 NF.corank = the corank of f (of type int)
 NF.inertiaIndex = the inertia index of f (of type int)
 NF.milnorNumber = the milnor number of f (of type int)
 NF.determinacy = an lower bound for the determinacy of f (of type int)

Note: The classification is done over the real numbers, so in contrast to `classify.lib`, the signs of coefficients of monomials where even exponents occur matter.
 The ground field must be \mathbb{Q} (the rational numbers). No field extensions of any kind nor floating point numbers are allowed.
 The monomial order must be local.
 The input polynomial must be contained in `maxideal(2)` and must be an isolated singularity of modality 0 or 1. The Milnor number is checked for being finite.
 In case of `NF.modality=1`, the parameter values are given as an element of a number field $\mathbb{Q}\mathbb{Q}[a]/(\text{minpoly})$, the coefficient ring of F in terms of the unique root of `minpoly` of the ring F.in in the interval specified in `NF.parameters` in conjunction with the parameter term.

Example:

```
LIB "realclassify.lib";
ring r = 0, (x,y,z), ds;
poly f = (x^2+3y-2z)^2+xyz-(x-y^3+x^2z^3)^3;
realclassify(f);

```

See also: [Section D.6.4.2 \[classify\]](#), page 1651.

D.6.19.2 realmorsesplit

Procedure from library `realclassify.lib` (see [Section D.6.19 \[realclassify.lib\]](#), page 1750).

Usage: `realmorsesplit(f[, mu]);` f poly, mu int

Return: a list consisting of the corank of f, the inertia index, an upper bound for the determinacy, and the residual form of f

Note: The characteristic of the basering must be zero, the monomial order must be local, f must be contained in `maxideal(2)` and the Milnor number of f must be finite.
The Milnor number of f can be provided as an optional parameter in order to avoid that it is computed again.

Example:

```

LIB "realclassify.lib";
ring r = 0, (x,y,z), ds;
poly f = (x2+3y-2z)^2+xyz-(x-y3+x2z3)^3;
realmorsesplit(f);
⇒ [1]:
⇒ 2
⇒ [2]:
⇒ 0

```

```

    ↦ [3] :
    ↦      3
    ↦ [4] :
    ↦      -x3+2/3xy2

```

See also: [Section D.6.4.8 \[morsesplit\]](#), page 1655.

D.6.19.3 milnornumber

Procedure from library `realclassify.lib` (see [Section D.6.19 \[realclassify_lib\]](#), page 1750).

Usage: `milnornumber(f); f poly`

Return: Milnor number of `f`, or -1 if the Milnor number is not finite

Note: The monomial order must be local.

Example:

```

LIB "realclassify.lib";
ring r = 0, (x,y), ds;
poly f = x3+y4;
milnornumber(f);
↦ 6

```

D.6.19.4 determinacy

Procedure from library `realclassify.lib` (see [Section D.6.19 \[realclassify_lib\]](#), page 1750).

Usage: `determinacy(f[, mu]); f poly, mu int`

Return: an upper bound for the determinacy of `f`

Note: The characteristic of the basering must be zero, the monomial order must be local, `f` must be contained in `maxideal(1)` and the Milnor number of `f` must be finite.
The Milnor number of `f` can be provided as an optional parameter in order to avoid that it is computed again.

Example:

```

LIB "realclassify.lib";
ring r = 0, (x,y), ds;
poly f = x3+xy3;
determinacy(f);
↦ 5

```

See also: [Section 5.1.55 \[highcorner\]](#), page 194; [Section D.6.19.3 \[milnornumber\]](#), page 1759.

D.6.19.5 addnondegeneratevariables

Procedure from library `realclassify.lib` (see [Section D.6.19 \[realclassify_lib\]](#), page 1750).

Usage: `addnondegeneratevariables(NFR); NFR NormalFormEquation`

Return: Adds squares of the non-degenerate variables (i.e. `var(cr+1)`, ..., `var(nvars(basering))` for corank `cr`) to the normalform `nf`, with signs according to the inertia index.

Example:

```

LIB "realclassify.lib";
ring r = 0, (x,y,z), ds;
poly f = (x2+3y-2z)^2+xyz-(x-y3+x2z3)^3;
list NFR = realclassify(f);
NFR[1];
  ↳ Corank = 2
  ↳ Inertia index = 0
  ↳ Normalform equation of type = D[4]-
  ↳ Normalform equation = x2y-y3
  ↳ Milnor number = 4
  ↳ Modality = 0
  ↳ Determinacy <= 3
  ↳
addnondegeneratevariables(NFR[1]);
  ↳ Corank = 2
  ↳ Inertia index = 0
  ↳ Normalform equation of type = D[4]-
  ↳ Normalform equation = z2+x2y-y3
  ↳ Milnor number = 4
  ↳ Modality = 0
  ↳ Determinacy <= 3
  ↳

```

See also: [Section D.6.19.2 \[realmorsesplit\]](#), page 1758.

D.6.19.6 HilbertClassPoly

Procedure from library `realclassify.lib` (see [Section D.6.19 \[realclassify.lib\]](#), page 1750).

Return: the monic polynomial of degree $h(D)$ in $\mathbb{Z}[X]$ of which $jOft((D+\text{sqr}(D))/2)$ is a root

Assume: D is a negative discriminant

Note: k is input for the procedure "jOft",
 $5*k$ is input for the procedure "sqr",
 $10*k$ describes the number of decimals being calculated in the complex numbers

Example:

```

LIB "realclassify.lib";
ring r = 0,x,dp;
bigint D=-23;
HilbertClassPoly(D,50);
  ↳ x3+3491750x2-5151296875x+12771880859375

```

D.6.20 sing.lib

Library: `sing.lib`

Purpose: Invariants of Singularities

Authors: Gert-Martin Greuel, email: greuel@mathematik.uni-kl.de
 Bernd Martin, email: martin@math.tu-cottbus.de

Procedures:

D.6.20.1 codim

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\], page 1760](#)).

Usage: `codim(id1,id2)`; `id1,id2` ideal or module, both must be standard bases

Return: int, which is:

1. the vectorspace dimension of `id1/id2` if `id2` is contained in `id1` and if this number is finite
2. -1 if the dimension of `id1/id2` is infinite
3. -2 if `id2` is not contained in `id1`

Compute: consider the Hilbert series $iv1(t)$ of `id1` and $iv2(t)$ of `id2`. If $\text{codim}(\text{id1},\text{id2})$ is finite, $q(t)=(iv2(t)-iv1(t))/(1-t)^n$ is rational, and the codimension is the sum of the coefficients of $q(t)$ (n = dimension of basering).

Example:

```
LIB "sing.lib";
ring r = 0,(x,y),dp;
ideal j = y6,x4;
ideal m = x,y;
attrib(m,"isSB",1); //let Singular know that ideals are a standard basis
attrib(j,"isSB",1);
codim(m,j);          // should be 23 (Milnor number -1 of y7-x5)
↦ 23
```

D.6.20.2 deform

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\], page 1760](#)).

Usage: `deform(id)`; `id`=ideal or poly

Return: matrix, columns are kbase of infinitesimal deformations

Example:

```
LIB "sing.lib";
ring r = 32003,(x,y,z),ds;
ideal i = xy,xz,yz;
matrix T = deform(i);
print(T);
↦ x,0,0,
↦ 0,0,z,
↦ 0,y,0
print(deform(x3+y5+z2));
↦ xy3,y3,xy2,y2,xy,y,x,1
```

D.6.20.3 dim_slocus

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\], page 1760](#)).

Usage: `dim_slocus(i)`; `i` ideal or poly

Return: dimension of singular locus of `i`

Example:

```
LIB "sing.lib";
ring r = 32003,(x,y,z),ds;
ideal i = x5+y6+z6,x2+2y2+3z2;
dim_slocus(i);
↪ 0
```

D.6.20.4 is_active

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\]](#), page 1760).

Usage: `is_active(f,id)`; `f` poly, `id` ideal or module

Return: 1 if `f` is an active element modulo `id` (i.e. $\dim(id) = \dim(id + f \cdot R^n) + 1$, if `id` is a submodule of R^n) resp. 0 if `f` is not active. The basering may be a quotient ring

Note: regular parameters are active but not vice versa (`id` may have embedded components).
`proc is_reg` tests whether `f` is a regular parameter

Example:

```
LIB "sing.lib";
ring r = 32003,(x,y,z),ds;
ideal i = yx3+y,yz3+y3z;
poly f = x;
is_active(f,i);
↪ 1
qring q = std(x4y5);
poly f = x;
module m = [yx3+x,yx3+y3x];
is_active(f,m);
↪ 0
```

D.6.20.5 is_ci

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\]](#), page 1760).

Usage: `is_ci(i)`; `i` ideal

Return: `intvec` = sequence of dimensions of ideals (`j[1],...,j[k]`), for $k=1,...,\text{size}(j)$, where `j` is minimal base of `i`. `i` is a complete intersection if last number equals `nvars-size(i)`

Note: $\dim(0\text{-ideal}) = -1$. You may first apply `simplify(i,10)`; in order to delete zeroes and multiples from set of generators
`printlevel >= 0`: display comments (default)

Example:

```
LIB "sing.lib";
int p = printlevel;
printlevel = 1; // display comments
ring r = 32003,(x,y,z),ds;
ideal i = x4+y5+z6,xyz,yx2+xz2+zy7;
is_ci(i);
↪ // complete intersection of dim 0
↪ // dim-sequence:
↪ 2,1,0
i = xy,yz;
is_ci(i);
```

```

⇒ // no complete intersection
⇒ // dim-sequence:
⇒ 2,2
printlevel = p;

```

D.6.20.6 is_is

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\]](#), page 1760).

Usage: `is_is(id)`; `id` ideal or poly

Return: `intvec` = sequence of dimensions of singular loci of ideals generated by `id[1]..id[i]`, $k = 1..size(id)$;
`dim(0-ideal) = -1`;
`id` defines an isolated singularity if last number is 0

Note: `printlevel >= 0`: display comments (default)

Example:

```

LIB "sing.lib";
int p      = printlevel;
printlevel = 1;
ring r      = 32003, (x,y,z), ds;
ideal i     = x2y, x4+y5+z6, yx2+xz2+zy7;
is_is(i);
⇒ // dim of singular locus = 0
⇒ // isolated singularity if last number is 0 in dim-sequence:
⇒ 2,1,0
poly f      = xy+yz;
is_is(f);
⇒ // dim of singular locus = 1
⇒ // isolated singularity if last number is 0 in dim-sequence:
⇒ 1
printlevel = p;

```

D.6.20.7 is_reg

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\]](#), page 1760).

Usage: `is_reg(f,id)`; `f` poly, `id` ideal or module

Return: 1 if multiplication with `f` is injective modulo `id`, 0 otherwise

Note: Let R be the basering and `id` a submodule of R^n . The procedure checks injectivity of multiplication with `f` on R^n/id . The basering may be a quotient ring.

Example:

```

LIB "sing.lib";
ring r = 32003, (x,y), ds;
ideal i = x8,y8;
ideal j = (x+y)^4;
i       = intersect(i,j);
poly f  = xy;
is_reg(f,i);
⇒ 0

```

D.6.20.8 is_regs

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\], page 1760](#)).

Usage: `is_regs(i[,id]);` `i` poly, `id` ideal or module (default: `id=0`)

Return: 1 if generators of `i` are a regular sequence modulo `id`, 0 otherwise

Note: Let R be the basering and `id` a submodule of R^n . The procedure checks injectivity of multiplication with `i[k]` on $R^n/\text{id}+i[1..k-1]$. The basering may be a quotient ring.
`printlevel >=0`: display comments (default)
`printlevel >=1`: display comments during computation

Example:

```
LIB "sing.lib";
int p      = printlevel;
printlevel = 1;
ring r1     = 32003,(x,y,z),ds;
ideal i     = x8,y8,(x+y)^4;
is_regs(i);
⇒ // checking whether element 1 is regular mod 1 .. 0
⇒ // checking whether element 2 is regular mod 1 .. 1
⇒ // checking whether element 3 is regular mod 1 .. 2
⇒ // elements 1..2 are regular, 3 is not regular mod 1..2
⇒ 0
module m    = [x,0,y];
i           = x8,(x+z)^4;;
is_regs(i,m);
⇒ // checking whether element 1 is regular mod 1 .. 0
⇒ // checking whether element 2 is regular mod 1 .. 1
⇒ // elements are a regular sequence of length 2
⇒ 1
printlevel = p;
```

D.6.20.9 locstd

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\], page 1760](#)).

Usage: `locstd (id);` `id` = ideal

Return: a standard basis for a local degree ordering

Note: the procedure homogenizes `id` w.r.t. a new 1st variable `@t@`, computes a SB w.r.t. $(dp(1), dp)$ and substitutes `@t@` by 1.
Hence the result is a SB with respect to an ordering which sorts first w.r.t. the order and then refines it with `dp`. This is a local degree ordering.
This is done in order to avoid cancellation of units and thus be able to use `option(contentSB);`

Example:

```
LIB "sing.lib";
ring R = 0,(x,y,z),ds;
ideal i = xyz+z5,2x2+y3+z7,3z5+y5;
locstd(i);
⇒ _[1]=y5+3z5
⇒ _[2]=3x4y3z8-4x3y3z9+6x2y4z9+3y5z10
```

```

⇒ _[3]=3x4z13-4x3z14+6x2yz14+3y2z15
⇒ _[4]=3x4yz12-4x3yz13+6x2y2z13+3y3z14
⇒ _[5]=2x2z9+x2y2z8+y3z9
⇒ _[6]=2x2y4z5+y7z5-3x2yz9
⇒ _[7]=6y2z10-3x2y3z8+4xy3z9-3y4z9
⇒ _[8]=3x2y2z8+3y3z9+2xy4z8
⇒ _[9]=18z14-4xy6z8+3y7z8-9x2yz12
⇒ _[10]=xyz+z5
⇒ _[11]=3xz6-y4z5
⇒ _[12]=3y3z6+2xy4z5-3xyz9
⇒ _[13]=y4z5-2xz9-xy2z8
⇒ _[14]=3z10+2xyz9+xy3z8
⇒ _[15]=2x2z5+y3z5-xyz8
⇒ _[16]=y4z-2xz5+yz8
⇒ _[17]=3z6+2xyz5-y2z8
⇒ _[18]=2x2+y3+z7

```

D.6.20.10 milnor

Procedure from library `sing.lib` (see [Section D.6.20 \[sing.lib\], page 1760](#)).

Usage: `milnor(i)`; *i* ideal or poly

Return: Milnor number of *i*, if *i* is ICIS (isolated complete intersection singularity) in generic form, resp. -1 if not

Note: use `proc nf_icis` to put generators in generic form
 `printlevel >=1`: display comments

Example:

```

LIB "sing.lib";
int p      = printlevel;
printlevel = 2;
ring r     = 32003,(x,y,z),ds;
ideal j    = x5+y6+z6,x2+2y2+3z2,xyz+yx;
milnor(j);
⇒ //sequence of discriminant numbers: 100,149,70
⇒ 21
poly f     = x7+y7+(x-y)^2*x2y2+z2;
milnor(f);
⇒ 28
printlevel = p;

```

D.6.20.11 nf_icis

Procedure from library `sing.lib` (see [Section D.6.20 \[sing.lib\], page 1760](#)).

Usage: `nf_icis(i)`; *i* ideal

Return: ideal = generic linear combination of generators of *i* if *i* is an ICIS (isolated complete intersection singularity), return *i* if not

Note: this proc is useful in connection with `proc milnor`
 `printlevel >=0`: display comments (default)

Example:

```

LIB "sing.lib";
int p      = printlevel;
printlevel = 1;
ring r      = 32003,(x,y,z),ds;
ideal i     = x3+y4,z4+yx;
nf_icis(i);
⇨ // complete intersection of dim 1
⇨ // dim-sequence:
⇨ // dim of singular locus = 0
⇨ // isolated singularity if last number is 0 in dim-sequence:
⇨ // dim of singular locus = 0
⇨ // isolated singularity if last number is 0 in dim-sequence:
⇨ // ICIS in generic form after 1 genericity loop(s)
⇨ _[1]=2xy+x3+y4+2z4
⇨ _[2]=xy+z4
ideal j     = x3+y4,xy,yz;
nf_icis(j);
⇨ // no complete intersection
⇨ // dim-sequence:
⇨ // no complete intersection
⇨ _[1]=x3+y4
⇨ _[2]=xy
⇨ _[3]=yz
printlevel = p;

```

D.6.20.12 slocus

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\], page 1760](#)).

Usage: `slocus(i); i ideal`

Return: ideal of singular locus of `i`. Quotient rings and rings with integer coefficients are currently not supported.

Example:

```

LIB "sing.lib";
ring r = 0,(u,v,w,x,y,z),dp;
ideal i = wx,wy,wz,vx,vy,vz,ux,uy,uz,y3-x2;;
slocus(i);
⇨ _[1]=x
⇨ _[2]=w
⇨ _[3]=v
⇨ _[4]=u
⇨ _[5]=y2

```

D.6.20.13 qhspectrum

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\], page 1760](#)).

Usage: `qhspectrum(f,w); f=poly, w=intvec`

Assume: `f` is a weighted homogeneous isolated singularity w.r.t. the weights given by `w`; `w` must consist of as many positive integers as there are variables of the basering

Compute: the spectral numbers of the `w`-homogeneous polynomial `f`, computed in a ring of characteristic 0

Return: intvec d, s_1, \dots, s_u where:
 $d = w\text{-degree}(f)$ and $s_i/d = i\text{-th spectral-number}(f)$
 No return value if basering has parameters or if f is no isolated singularity, displays a warning in this case.

Example:

```
LIB "sing.lib";
ring r;
poly f=x3+y5+z2;
intvec w=10,6,15;
qhspectrum(f,w);
↪ 30,1,7,11,13,17,19,23,29
// the spectrum numbers are:
// 1/30,7/30,11/30,13/30,17/30,19/30,23/30,29/30
```

D.6.20.14 Tjurina

Procedure from library `sing.lib` (see [Section D.6.20 \[sing.lib\]](#), page 1760).

Usage: Tjurina(id[,<any>]); id=ideal or poly

Assume: id=ICIS (isolated complete intersection singularity)

Return: standard basis of Tjurina-module of id,
 of type module if id=ideal, resp. of type ideal if id=poly. If a second argument is present (of any type) return a list:
 [1] = Tjurina number,
 [2] = k-basis of miniversal deformation,
 [3] = SB of Tjurina module,
 [4] = Tjurina module

Display: Tjurina number if printlevel ≥ 0 (default)

Note: Tjurina number = -1 implies that id is not an ICIS

Example:

```
LIB "sing.lib";
int p      = printlevel;
printlevel = 1;
ring r      = 0,(x,y,z),ds;
poly f      = x5+y6+z7+xyz;           // singularity T[5,6,7]
list T      = Tjurina(f,"");
↪ // Tjurina number = 16
show(T[1]);                             // Tjurina number, should be 16
↪ // int, size 1
↪ 16
show(T[2]);                             // basis of miniversal deformation
↪ // ideal, 16 generator(s)
↪ z6,
↪ z5,
↪ z4,
↪ z3,
↪ z2,
↪ z,
↪ y5,
↪ y4,
```

```

    ↪ y3,
    ↪ y2,
    ↪ y,
    ↪ x4,
    ↪ x3,
    ↪ x2,
    ↪ x,
    ↪ 1
    show(T[3]);                // SB of Tjurina ideal
    ↪ // ideal, 6 generator(s)
    ↪ xy+7z6,
    ↪ xz+6y5,
    ↪ yz+5x4,
    ↪ 5x5-6y6,
    ↪ y6,
    ↪ z7
    show(T[4]); "";           // Tjurina ideal
    ↪ // ideal, 4 generator(s)
    ↪ yz+5x4,
    ↪ xz+6y5,
    ↪ xy+7z6,
    ↪ xyz+x5+y6+z7
    ↪
    ideal j      = x2+y2+z2,x2+2y2+3z2;
    show(kbase(Tjurina(j)));  // basis of miniversal deformation
    ↪ // Tjurina number = 5
    ↪ // module, 5 generator(s)
    ↪ [z]
    ↪ [y]
    ↪ [x]
    ↪ [1]
    ↪ [0,1]
    hilb(Tjurina(j));         // Hilbert series of Tjurina module
    ↪ // Tjurina number = 5
    ↪ (-3t4+7t3-3t2-3t+2) / (1-t)^3
    ↪ (3t+2) / (1-t)^0
    ↪ // dimension (local)   = 0
    ↪ // multiplicity = 5
    printlevel = p;

```

D.6.20.15 tjurina

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\]](#), page 1760).

Usage: `tjurina(id);` `id`=ideal or poly

Assume: `id`=ICIS (isolated complete intersection singularity)

Return: `int` = Tjurina number of `id`

Note: Tjurina number = -1 implies that `id` is not an ICIS

Example:

```

LIB "sing.lib";
ring r=32003,(x,y,z),(c,ds);

```

```
ideal j=x2+y2+z2,x2+2y2+3z2;
tjurina(j);
↪ 5
```

D.6.20.16 T_1

Procedure from library `sing.lib` (see [Section D.6.20 \[sing.lib\], page 1760](#)).

Usage: `T_1(id[,<any>]);` `id` = ideal or poly

Return: `T_1(id)`: of type module/ideal if `id` is of type ideal/poly. We call `T_1(id)` the `T_1`-module of `id`. It is a std basis of the presentation of 1st order deformations of `P/id`, if `P` is the basering. If a second argument is present (of any type) return a list of 3 modules:

`[1]` = `T_1(id)`

`[2]` = generators of normal bundle of `id`, lifted to `P`

`[3]` = module of relations of `[2]`, lifted to `P`

(note: `transpose[3]*[2]=0 mod id`)

The list contains all non-easy objects which must be computed to get `T_1(id)`.

Display: `k`-dimension of `T_1(id)` if `printlevel >= 0` (default)

Note: `T_1(id)` itself is usually of minor importance. Nevertheless, from it all relevant information can be obtained. The most important are probably `vdim(T_1(id))`; (which computes the Tjurina number), `hilb(T_1(id))`; and `kbase(T_1(id))`.

If `T_1` is called with two arguments, then `matrix([2])*(kbase([1]))` represents a basis of 1st order semiuniversal deformation of `id` (use `proc 'deform'`, to get this in a direct way).

For a complete intersection the `proc Tjurina` is faster.

Example:

```
LIB "sing.lib";
int p      = printlevel;
printlevel = 1;
ring r      = 32003,(x,y,z),(c,ds);
ideal i     = xy,xz,yz;
module T    = T_1(i);
↪ // dim T_1 = 3
vdim(T);
↪ 3
list L=T_1(i,"");
↪ // dim T_1 = 3
module kB   = kbase(L[1]);
print(matrix(L[2])*matrix(kB)); // basis of 1st order miniversal deformation
↪ 0,0,0,
↪ z,0,0,
↪ 0,y,z
show(L[2]); // presentation of normal bundle
↪ // module, 6 generator(s)
↪ [x]
↪ [y,z]
↪ [0,x,y]
↪ [0,z]
↪ [0,0,y]
↪ [0,0,z]
```

```

print(L[3]);                // relations of i
⇨ z, 0,
⇨ -y,y,
⇨ 0, -x
print(transpose(matrix(L[3]))*matrix(L[2])); // should be 0 (mod i)
⇨ xz,0, -xy,-yz,0, 0,
⇨ 0, yz,0, yz, -xy,-xz
printlevel = p;

```

D.6.20.17 T_2

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\]](#), page 1760).

Usage: `T_2(id[,<any>]);` `id` = ideal

Return: `T_2(id)`: `T_2`-module of `id`. This is a std basis of a presentation of the module of obstructions of $R=P/id$, if P is the basering. If a second argument is present (of any type) return a list of 4 modules and 1 ideal:

```

[1]= T_2(id)
[2]= standard basis of id (ideal)
[3]= module of relations of id (=1st syzygy module of id)
[4]= presentation of syz/kos
[5]= relations of Hom_P([3]/kos,R), lifted to P

```

The list contains all non-easy objects which must be computed to get `T_2(id)`.

Display: `k`-dimension of `T_2(id)` if `printlevel` ≥ 0 (default)

Note: The most important information is probably `vdim(T_2(id))`. Use `proc miniversal` to get equations of the miniversal deformation.

Example:

```

LIB "sing.lib";
int p      = printlevel;
printlevel = 1;
ring r     = 32003,(x,y),(c,dp);
ideal j    = x6-y4,x6y6,x2y4-x5y2;
module T   = T_2(j);
⇨ // dim T_2 = 6
vdim(T);
⇨ 6
hilb(T);"";
⇨ (t5-t3-t2+1) / (1-t)^2
⇨ (t3+2t2+2t+1) / (1-t)^0
⇨ // dimension (affine) = 0
⇨ // degree (affine) = 6
⇨
ring r1    = 0,(x,y,z),dp;
ideal id   = xy,xz,yz;
list L     = T_2(id,"");
⇨ // dim T_2 = 0
vdim(L[1]);                // vdim of T_2
⇨ 0
print(L[3]);                // syzygy module of id
⇨ -z,-z,
⇨ y, 0,

```

```

    ↦ 0, x
    printlevel = p;

```

D.6.20.18 T_12

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\]](#), page 1760).

Usage: `T_12(i[,any]); i = ideal`

Return: `T_12(i)`: list of 2 modules:
 * standard basis of `T_1`-module = `T_1(i)`, 1st order deformations
 * standard basis of `T_2`-module = `T_2(i)`, obstructions of $R=P/i$
 If a second argument is present (of any type) return a list of 9 modules, matrices, integers:
 [1]= standard basis of `T_1`-module
 [2]= standard basis of `T_2`-module
 [3]= `vdim` of `T_1`
 [4]= `vdim` of `T_2`
 [5]= matrix, whose cols present infinitesimal deformations
 [6]= matrix, whose cols are generators of relations of $i(=syz(i))$
 [7]= matrix, presenting $\text{Hom}_P(syz/kos, R)$, lifted to P
 [8]= presentation of `T_1`-module, no std basis
 [9]= presentation of `T_2`-module, no std basis

Display: `k`-dimension of `T_1` and `T_2` if `printlevel` ≥ 0 (default)

Note: Use proc `miniversal` from `deform.lib` to get miniversal deformation of i , the list contains all objects used by proc `miniversal`.

Example:

```

LIB "sing.lib";
int p      = printlevel;
printlevel = 1;
ring r      = 199, (x,y,z,u,v), (c, ws(4,3,2,3,4));
ideal i     = xz-y2, yz2-xu, xv-yzu, yu-z3, z2u-yv, zv-u2;
//a cyclic quotient singularity
list L      = T_12(i,1);
↦ // dim T_1 = 5
↦ // dim T_2 = 3
print(L[5]);           //matrix of infin. deformations
↦ 0, 0, 0, 0, 0,
↦ yz, y, z2, 0, 0,
↦ -z3, -z2, -zu, yz, yu,
↦ -z2, -z, -u, 0, 0,
↦ zu, u, v, -z2, -zu,
↦ 0, 0, 0, u, v
printlevel = p;

```

D.6.20.19 tangentcone

Procedure from library `sing.lib` (see [Section D.6.20 \[sing_lib\]](#), page 1760).

Usage: `tangentcone(id [,n]); id = ideal, n = int`

Return: the tangent cone of id

Note: The procedure works for any monomial ordering.
If $n=0$ use `std` w.r.t. local ordering `ds`, if $n=1$ use `locstd`.

Example:

```
LIB "sing.lib";
ring R = 0,(x,y,z),ds;
ideal i = 7xyz+z5,x2+y3+z7,5z5+y5;
tangentcone(i);
↪ _[1]=x2
↪ _[2]=7xyz
↪ _[3]=y5+5z5
↪ _[4]=7y4z
↪ _[5]=35z6
```

D.6.21 spcurve_lib

Library: spcurve.lib

Purpose: Deformations and Invariants of CM-codim 2 Singularities

Author: Anne Fruehbis-Krueger, anne@mathematik.uni-kl.de

Procedures:

D.6.21.1 isCMcod2

Procedure from library `spcurve.lib` (see [Section D.6.21 \[spcurve.lib\]](#), page 1772).

Usage: isCMcod2(i); i an ideal

Return: presentation matrix of i , if i is Cohen-Macaulay of codimension 2
a zero matrix otherwise

Example:

```
LIB "spcurve.lib";
ring r=32003,(x,y,z),ds;
ideal i=xz,yz,x^3-y^4;
print(isCMcod2(i));
↪ -y, -x2,
↪ x, y3,
↪ 0, z
```

D.6.21.2 CMtype

Procedure from library `spcurve.lib` (see [Section D.6.21 \[spcurve.lib\]](#), page 1772).

Usage: CMtype(i); i an ideal, CM of codimension 2

Return: Cohen-Macaulay type of i (integer)
(-1, if i is not Cohen-Macaulay of codimension 2)

Example:

```
LIB "spcurve.lib";
ring r=32003,(x,y,z),ds;
ideal i=xy,xz,yz;
CMtype(i);
↪ 2
```

D.6.21.3 matrixT1

Procedure from library `spcurve.lib` (see [Section D.6.21 \[spcurve.lib\]](#), page 1772).

Usage: `matrixT1(M,n)`; M matrix, n integer

Assume: M is a presentation matrix of an ideal i , CM of codimension 2; consider i as a family of ideals in a ring in the first n variables where the remaining variables are considered as parameters

Return: list consisting of the $k \times (k+1)$ matrix M and a module K_M such that $T1 = \text{Mat}(k, k+1; R)/K_M$ is the space of first order deformations of i

Example:

```
LIB "spcurve.lib";
ring r=32003,(x(1),x(2),x(3)),ds;
ideal curve=x(1)*x(2),x(1)*x(3),x(2)*x(3);
matrix M=isCMcod2(curve);
matrixT1(M,3);
⇒ [1]:
⇒  _[1,1]=0
⇒  _[1,2]=-x(3)
⇒  _[2,1]=-x(2)
⇒  _[2,2]=x(2)
⇒  _[3,1]=x(1)
⇒  _[3,2]=0
⇒ [2]:
⇒  _[1]=gen(5)
⇒  _[2]=gen(4)-gen(3)
⇒  _[3]=-gen(2)
⇒  _[4]=x(1)*gen(5)-x(2)*gen(3)
⇒  _[5]=x(1)*gen(6)-x(2)*gen(4)
⇒  _[6]=x(2)*gen(3)-x(3)*gen(1)
⇒  _[7]=x(2)*gen(4)-x(3)*gen(2)
⇒  _[8]=-x(3)*gen(2)
⇒  _[9]=x(2)*gen(2)-x(2)*gen(1)
⇒  _[10]=x(1)*gen(1)
⇒  _[11]=-x(3)*gen(4)
⇒  _[12]=x(2)*gen(4)-x(2)*gen(3)
⇒  _[13]=x(1)*gen(3)
⇒  _[14]=-x(3)*gen(6)
⇒  _[15]=x(2)*gen(6)-x(2)*gen(5)
⇒  _[16]=x(1)*gen(5)
```

D.6.21.4 semiCMcod2

Procedure from library `spcurve.lib` (see [Section D.6.21 \[spcurve.lib\]](#), page 1772).

Usage: `semiCMcod2(M,t1[,s])`; M matrix, $t1$ module, s any

Assume: M is a presentation matrix of an ideal i , CM of codimension 2, and $t1$ is a presentation of the space of first order deformations of i ($(M,t1)$ as returned by the procedure `matrixT1`)

Return: new ring in which the ideal `semi` describing the semiuniversal deformation of i ; if the optional third argument is given, the perturbation matrix of the semiuniversal deformation is returned instead of the ideal.

Note: The current basering should not contain any variables named $A(j)$ where j is some integer!

Example:

```
LIB "spcurve.lib";
ring r=32003,(x(1),x(2),x(3)),ds;
ideal curve=x(1)*x(2),x(1)*x(3),x(2)*x(3);
matrix M=isCMcod2(curve);
list l=matrixT1(M,3);
def rneu=semiCMcod2(l[1],std(l[2]));
setring rneu;
semi;
⇒ semi[1]=A(2)*A(3)-x(2)*A(3)-x(1)*x(2)
⇒ semi[2]=A(1)*A(3)+x(1)*x(3)
⇒ semi[3]=-x(2)*A(1)-x(3)*A(2)+x(2)*x(3)
```

D.6.21.5 discr

Procedure from library `spcurve.lib` (see [Section D.6.21 \[spcurve.lib\]](#), page 1772).

Usage: `discr(sem,n)`; `sem` ideal, `n` integer

Assume: `sem` is the versal deformation of an ideal of codimension 2.
The first `n` variables of the ring are treated as variables all the others as parameters.

Return: ideal describing the discriminant

Note: This is not a powerful algorithm!

Example:

```
LIB "spcurve.lib";
ring r=32003,(x(1),x(2),x(3)),ds;
ideal curve=x(1)*x(2),x(1)*x(3),x(2)*x(3);
matrix M=isCMcod2(curve);
list l=matrixT1(M,3);
def rneu=semiCMcod2(l[1],std(l[2]));
setring rneu;
discr(semi,3);
⇒ _[1]=A(1)*A(2)*A(3)
```

D.6.21.6 qhmatrix

Procedure from library `spcurve.lib` (see [Section D.6.21 \[spcurve.lib\]](#), page 1772).

Usage: `qhmatrix(M)`; `M` a $k \times (k+1)$ matrix

Return: list, consisting of an integer vector containing the weights of the variables of the basering and an integer matrix giving the weights of the entries of `M`, if `M` is quasihomogeneous; zero integer vector and zero integer matrix, if `M` is not quasihomogeneous, i.e. does not allow row and column weights

Example:

```
LIB "spcurve.lib";
ring r=0,(x,y,z),ds;
matrix M[3][2]=z,0,y,x,x^3,y;
qhmatrix(M);
```

```

↳ [1]:
↳   1,2,1
↳ [2]:
↳   1,0,
↳   2,1,
↳   3,2
pmat(M);
↳ z,  0,
↳ y,  x,
↳ x3, y

```

D.6.21.7 relweight

Procedure from library `spcurve.lib` (see [Section D.6.21 \[spcurve.lib\]](#), page 1772).

Usage: `relweight(N,W,a)`; N matrix, W intmat, a intvec

Assume: N is a non-zero matrix
W is an integer matrix of the same size as N
a is an integer vector giving the weights of the variables

Return: integer, $\max(a\text{-weighted order}(N_{ij}) - W_{ij} \mid \text{all entries } ij)$
string "ERROR" if sizes do not match

Example:

```

LIB "spcurve.lib";
ring r=32003,(x,y,z),ds;
matrix N[2][3]=z,0,y,x,x^3,y;
intmat W[2][3]=1,1,1,1,1,1;
intvec a=1,1,1;
relweight(N,W,a);
↳ 2

```

D.6.21.8 posweight

Procedure from library `spcurve.lib` (see [Section D.6.21 \[spcurve.lib\]](#), page 1772).

Usage: `posweight(M,t1,n[,s])`; M matrix, t1 module, n int, s string
n=0 : all deformations of non-negative weight
n=1 : only non-constant deformations of non-negative weight
n=2 : all deformations of positive weight

Assume: M is a presentation matrix of a Cohen-Macaulay codimension 2 ideal and t1 is its T1 space in matrix notation

Return: new ring containing a list posw, consisting of a presentation matrix describing the deformation given by the generators of T1 of non-negative/positive weight and the weight vector for the new variables

Note: The current basering should not contain any variables named T(i) where i is some integer!

Example:

```

LIB "spcurve.lib";
ring r=32003,(x(1),x(2),x(3)),ds;

```

```

ideal curve=(x(3)-x(1)^2)*x(3),(x(3)-x(1)^2)*x(2),x(2)^2-x(1)^7*x(3);
matrix M=isCMcod2(curve);
list l=matrixT1(M,3);
def rneu=posweight(l[1],std(l[2]),0);
setring rneu;
pmat(posw[1]);
↪ T(2)+x(1)*T(1), -x(3)+x(1)^2,
↪ -x(3),          x(2),
↪ x(2),          -x(1)^7
posw[2];
↪ 3,1

```

D.6.21.9 KSpencerKernel

Procedure from library `spcurve.lib` (see [Section D.6.21 \[spcurve.lib\]](#), page 1772).

- Usage:** KSpencerKernel(M[,s][,v]); M matrix, s string, v intvec
optional parameters (please specify in this order, if both are present):
* s = first of the names of the new rings
e.g. "R" leads to ring names R and R1
* v of size n(n+1) leads to the following module ordering
gen(v[1]) > gen(v[2]) > ... > gen(v[n(n+1)]) where the matrix entry ij corresponds to
gen((i-1)*n+j)
- Assume:** M is a quasihomogeneous n x (n+1) matrix where the n minors define an isolated space curve singularity
- Return:** new ring containing the coefficient matrix KS representing the kernel of the Kodaira-Spencer map of the family of non-negative deformations having the given singularity as special fibre
- Note:** * the initial basering should not contain variables with name e(i) or T(i), since those variable names will internally be used by the script
* setting an intvec with 5 entries and name watchProgress shows the progress of the computations:
watchProgress[1]>0 => option(prot) in groebner commands
watchProgress[2]>0 => trace output for highcorner
watchProgress[3]>0 => output of deformed matrix
watchProgress[4]>0 => result of elimination step
watchProgress[4]>1 => trace output of multiplications with xyz and subsequent reductions
watchProgress[5]>0 => matrix representing the kernel using print

Example:

```

LIB "spcurve.lib";
ring r=0,(x,y,z),ds;
matrix M[3][2]=z-x^7,0,y^2,z,x^9,y;
def rneu=KSpencerKernel(M,"ar");
setring rneu;
basing;
↪ // coefficients: QQ
↪ // number of vars : 17
↪ //          block 1 : ordering Ws
↪ //          : names   e(1) e(2) e(3) e(4) e(5) e(6) x y z

```

```

⇒ //          : weights  -21 -10 -32 -21 -27 -16 3 16 21
⇒ //          block  2 : ordering wp
⇒ //          : names    T(1) T(2) T(3) T(4) T(5) T(6) T(7) T(8)
⇒ //          : weights   8   5   2  10   7   4   1   2
⇒ //          block  3 : ordering C
print(KS);
⇒ T(7), 0, 0, 0, 0, 0, 0, 0,
⇒ KS[2,1],6*T(3), 3*T(7), 0, 0, 0, 0, 0,
⇒ KS[3,1],KS[3,2],KS[3,3],6*T(3),3*T(7),0, 0, 0,
⇒ 10*T(4),8*T(1), 7*T(5), 5*T(2),4*T(6),2*T(8),2*T(3),T(7)

```

D.6.22 spectrum_lib

Library: spectrum.lib

Purpose: Singularity Spectrum for Nondegenerate Singularities

Author: S. Endrass

Procedures:

D.6.22.1 spectrumnd

Procedure from library `spectrum.lib` (see [Section D.6.22 \[spectrum_lib\]](#), page 1777).

Usage: spectrumnd(f[,1]); poly f

Assume: basering has characteristic 0 and local ordering,
f has isolated singularity at 0 and nondegenerate principal part

Return:

list S:
ideal S[1]: spectral numbers in increasing order
intvec S[2]:
int S[2][i]: multiplicity of spectral number S[1][i]

Note: if a second argument 1 is given,
no test for a degenerate principal part will be done
SEE_ALSO: gmssing_lib

Example:

```

LIB "spectrum.lib";
ring R=0,(x,y),ds;
poly f=x^31+x^6*y^7+x^2*y^12+x^13*y^2+y^29;
list s=spectrumnd(f);
size(s[1]);
⇒ 174
s[1][22];
⇒ -27/58
s[2][22];
⇒ 2

```

D.6.23 surfacesignature_lib

Library: surfacesignature.lib

Purpose: signature of surface singularity

Authors: Gerhard Pfister pfister@mathematik.uni-kl.de
 Muhammad Ahsan Banyamin ahsanbanyamin@gmail.com
 Stefan Steidel steidel@mathematik.uni-kl.de

Overview: A library for computing the signature of irreducible surface singularity. The signature of a surface singularity is defined in [3]. The algorithm we use has been proposed in [9].

Let g in $C[x,y]$ define an isolated curve singularity at 0 in C^2 and $f:=z^N+g(x,y)$. The zero-set $V:=V(f)$ in C^3 of f has an isolated singularity at 0. For a small $\epsilon>0$ let $V_\epsilon:=V(f-\epsilon)$ in C^3 be the Milnor fibre of $(V,0)$ and $s: H_2(V_\epsilon, R) \times H_2(V_\epsilon, R) \rightarrow R$ be the intersection form (cf. [1],[7]). $H_2(V_\epsilon, R)$ is an m -dimensional R -vector space, m the Milnor number of $(V,0)$ (cf. [1],[4],[5],[6]), and s is a symmetric bilinear form. Let $\text{sigma}(f)$ be the signature of s , called the signature of the surface singularity $(V,0)$. Formulae to compute the signature are given by Nemethi (cf. [8],[9]) and van Doorn, Steenbrink (cf. [2]).

We have implemented three approaches using Puiseux expansions, the resolution of singularities resp. the spectral pairs of the singularity.

Procedures:

D.6.23.1 signatureBrieskorn

Procedure from library `surfacesignature.lib` (see [Section D.6.23 \[surfacesignature.lib\]](#), [page 1777](#)).

Usage: `signatureBrieskorn(a1,a2,a3);` $a1,a2,a3 = \text{integers}$

Return: signature of Brieskorn singularity $x^{a1}+y^{a2}+z^{a3}$

Example:

```
LIB "surfacesignature.lib";
ring R = 0,x,dp;
signatureBrieskorn(11,3,5);
--> -48
```

D.6.23.2 signaturePuisseux

Procedure from library `surfacesignature.lib` (see [Section D.6.23 \[surfacesignature.lib\]](#), [page 1777](#)).

Usage: `signaturePuisseux(N,f)`; $N = \text{int}$, $f = \text{irreducible poly in 2 variables}$

Return: signature of surface singularity defined by $z^N + f(x,y) = 0$

Example:

```
LIB "surfacesignature.lib";
ring r = 0,(x,y),dp;
int N = 3;
poly f = x15-21x14+8x13y-6x13-16x12y+20x11y2-x12+8x11y-36x10y2
+24x9y3+4x9y2-16x8y3+26x7y4-6x6y4+8x5y5+4x3y6-y8;
signaturePuisseux(N,f);
↪ -92
```

D.6.23.3 signatureNemethi

Procedure from library `surfacesignature.lib` (see [Section D.6.23 \[surfacesignature.lib\]](#), [page 1777](#)).

Usage: `signatureNemethi(N,f)`; $N = \text{integer}$, $f = \text{reduced poly in 2 variables}$, $\#$ empty or 1,2,3
 - if $\#[1] = 1$ then resolution of singularity is used
 - if $\#[1] = 2$ then spectral pairs are used
 - if $\#$ is empty then both upper variants are used in parallel and the fastest returns the result

Return: signature of surface singularity defined by $z^N + f(x,y) = 0$

Remark: computes the signature of some special surface singularities

Example:

```
LIB "surfacesignature.lib";
ring r = 0,(x,y),dp;
int N = 3;
poly f = x15-21x14+8x13y-6x13-16x12y+20x11y2-x12+8x11y-36x10y2
+24x9y3+4x9y2-16x8y3+26x7y4-6x6y4+8x5y5+4x3y6-y8;
signatureNemethi(N,f,1);
↪ -92
printlevel = 1;
signatureNemethi(N,f);
↪ Resolution of singularity has been used.
↪ -92
```

D.7 Invariant theory

D.7.1 finvar.lib

Library: `finvar.lib`

Purpose: Invariant Rings of Finite Groups

Author: Agnes E. Heydtmann, contact via Wolfram Decker: decker@mathematik.uni-kl.de Simon A. King, email: simon.king@nuigalway.ie

Overview: A library for computing polynomial invariants of finite matrix groups and generators of related varieties. The algorithms are based on B. Sturmfels, G. Kemper, S. King and W. Decker et al..

Procedures:

D.7.1.1 invariant_ring

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\]](#), page 1779).

Usage: `invariant_ring(G1,G2,...[,flags]);`
`G1,G2,...:` <matrices> generating a finite matrix group, `flags:` an optional <intvec> with three entries: if the first one equals 0, the program attempts to compute the Molien series and Reynolds operator, if it equals 1, the program is told that the Molien series should not be computed, if it equals -1 characteristic 0 is simulated, i.e. the Molien series is computed as if the base field were characteristic 0 (the user must choose a field of large prime characteristic, e.g. 32003) and if the first one is anything else, it means that the characteristic of the base field divides the group order (i.e. it will not even be attempted to compute the Reynolds operator or Molien series), the second component should give the size of intervals between canceling common factors in the expansion of Molien series, 0 (the default) means only once after generating all terms, in prime characteristic also a negative number can be given to indicate that common factors should always be canceled when the expansion is simple (the root of the extension field occurs not among the coefficients)

Return: primary and secondary invariants for any matrix representation of a finite group

Display: information about the various stages of the program if the third flag does not equal 0

Theory: Bases of homogeneous invariants are generated successively and those are chosen as primary invariants that lower the dimension of the ideal generated by the previously found invariants (see "Generating a Noetherian Normalization of the Invariant Ring of a Finite Group" by Decker, Heydtmann, Schreyer (1998)). In the non-modular case secondary invariants are calculated by finding a basis (in terms of monomials) of the basering modulo the primary invariants, mapping to invariants with the Reynolds operator and using those or their power products such that they are linearly independent modulo the primary invariants (see "Some Algorithms in Invariant Theory of Finite Groups" by Kemper and Steel (1997)). In the modular case they are generated according to "Generating Invariant Rings of Finite Groups over Arbitrary Fields" by Kemper (1996).

Example:

```
LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
matrix P,S,IS=invariant_ring(A);
print(P);
  ↳ z2,x2+y2,x2y2
print(S);
  ↳ 1,xyz,x2z-y2z,x3y-xy3
print(IS);
  ↳ xyz,x2z-y2z,x3y-xy3
```

D.7.1.2 invariant_ring_random

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `invariant_ring_random(G1,G2,...,r[,flags]);`
`G1,G2,...:` <matrices> generating a finite matrix group, `r:` an <int> where $-|r|$ to $|r|$ is the range of coefficients of random combinations of bases elements that serve as primary invariants, `flags:` an optional <intvec> with three entries: if the first equals 0, the program attempts to compute the Molien series and Reynolds operator, if it equals 1, the program is told that the Molien series should not be computed, if it equals -1 characteristic 0 is simulated, i.e. the Molien series is computed as if the base field were characteristic 0 (the user must choose a field of large prime characteristic, e.g. 32003) and if the first one is anything else, then the characteristic of the base field divides the group order (i.e. we will not even attempt to compute the Reynolds operator or Molien series), the second component should give the size of intervals between canceling common factors in the expansion of the Molien series, 0 (the default) means only once after generating all terms, in prime characteristic also a negative number can be given to indicate that common factors should always be canceled when the expansion is simple (the root of the extension field does not occur among the coefficients)
- Return:** primary and secondary invariants for any matrix representation of a finite group
- Display:** information about the various stages of the program if the third flag does not equal 0
- Theory:** is the same as for `invariant_ring` except that random combinations of basis elements are chosen as candidates for primary invariants and hopefully they lower the dimension of the previously found primary invariants by the right amount.

Example:

```
LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
matrix P,S,IS=invariant_ring_random(A,1);
print(P);
  ↪ z2,x2+y2,x4+y4-z4
print(S);
  ↪ 1,xyz,x2z-y2z,x3y-xy3
print(IS);
  ↪ xyz,x2z-y2z,x3y-xy3
```

D.7.1.3 primary_invariants

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `primary_invariants(G1,G2,...[,flags]);`
`G1,G2,...:` <matrices> generating a finite matrix group, `flags:` an optional <intvec> with three entries, if the first one equals 0 (also the default), the programme attempts to compute the Molien series and Reynolds operator, if it equals 1, the programme is told that the Molien series should not be computed, if it equals -1 characteristic 0 is simulated, i.e. the Molien series is computed as if the base field were characteristic 0 (the user must choose a field of large prime characteristic, e.g. 32003) and if the first one is anything else, it means that the characteristic of the base field divides the group order, the second component should give the size of intervals between canceling common factors in the expansion of the Molien series, 0 (the default) means only once after generating all terms, in prime characteristic also a negative number can be given

to indicate that common factors should always be canceled when the expansion is simple (the root of the extension field occurs not among the coefficients)

Display: information about the various stages of the programme if the third flag does not equal 0

Return: primary invariants (type <matrix>) of the invariant ring and if computable Reynolds operator (type <matrix>) and Molien series (type <matrix>) or ring name (type string) where the Molien series can be found in the char p case; if the first flag is 1 and we are in the non-modular case then an <intvec> is returned giving some of the degrees where no non-trivial homogeneous invariants can be found

Theory: Bases of homogeneous invariants are generated successively and those are chosen as primary invariants that lower the dimension of the ideal generated by the previously found invariants (see paper "Generating a Noetherian Normalization of the Invariant Ring of a Finite Group" by Decker, Heydtmann, Schreyer (1998)).

Example:

```
LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=primary_invariants(A);
print(L[1]);
↪ z2,x2+y2,x2y2
```

D.7.1.4 primary_invariants_random

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\]](#), page 1779).

Usage: `primary_invariants_random(G1,G2,...,r[,flags]);`
`G1,G2,...:` <matrices> generating a finite matrix group, `r:` an <int> where $-|r|$ to $|r|$ is the range of coefficients of the random combinations of bases elements, `flags:` an optional <intvec> with three entries, if the first one equals 0 (also the default), the programme attempts to compute the Molien series and Reynolds operator, if it equals 1, the programme is told that the Molien series should not be computed, if it equals -1 characteristic 0 is simulated, i.e. the Molien series is computed as if the base field were characteristic 0 (the user must choose a field of large prime characteristic, e.g. 32003) and if the first one is anything else, it means that the characteristic of the base field divides the group order, the second component should give the size of intervals between canceling common factors in the expansion of the Molien series, 0 (the default) means only once after generating all terms, in prime characteristic also a negative number can be given to indicate that common factors should always be canceled when the expansion is simple (the root of the extension field does not occur among the coefficients)

Display: information about the various stages of the programme if the third flag does not equal 0

Return: primary invariants (type <matrix>) of the invariant ring and if computable Reynolds operator (type <matrix>) and Molien series (type <matrix>), if the first flag is 1 and we are in the non-modular case then an <intvec> is returned giving some of the degrees where no non-trivial homogeneous invariants can be found

Theory: Bases of homogeneous invariants are generated successively and random linear combinations are chosen as primary invariants that lower the dimension of the ideal generated by the previously found invariants (see "Generating a Noetherian Normalization of the Invariant Ring of a Finite Group" by Decker, Heydtmann, Schreyer (1998)).

Example:

```
LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=primary_invariants_random(A,1);
print(L[1]);
↪ z2,x2+y2,x4+y4-z4
```

D.7.1.5 invariant_algebra_reynolds

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\]](#), page 1779).

- Usage:** `invariant_algebra_reynolds(REY[,v]);`
 REY: a $g \times n$ <matrix> representing the Reynolds operator of a finite matrix group, where g is the group order and n is the number of variables of the basering;
 v: an optional <int>
- Return:** A minimal homogeneous generating set of the invariant ring, type <matrix>
- Assume:** We are in the non-modular case, i.e., the characteristic of the basering does not divide the group order;
 REY is the 1st return value of `group_reynolds()`, `reynolds_molien()` or the second one of `primary_invariants()`
- Display:** Information on the progress of computations if v does not equal 0
- Theory:** We do an incremental search in increasing degree d . Generators of the invariant ring are found among the Reynolds images of monomials of degree d . The generators are chosen by Groebner basis techniques (see S. King: Minimal generating sets of non-modular invariant rings of finite groups).
- Note:** `invariant_algebra_reynolds` should not be used in rings with weighted orders.

Example:

```
LIB "finvar.lib";
ring R=0,(a,b,c,d),dp;
matrix A[4][4]=
0,0,1,0,
0,0,0,1,
1,0,0,0,
0,1,0,0;
list L = group_reynolds(A);
matrix G = invariant_algebra_reynolds(L[1],1);
↪ We have 4 relevant monomials in degree 1
↪ We found generator number 1 in degree 1
↪ We found generator number 2 in degree 1
↪ Computing Groebner basis up to the new degree 2
↪ We have 3 relevant monomials in degree 2
↪ We found generator number 3 in degree 2
↪ We found generator number 4 in degree 2
↪ We found generator number 5 in degree 2
↪ Computing Groebner basis up to the new degree 3
↪ We found the degree bound 2
↪ We went beyond the degree bound, so, we are done!
G;
↪ G[1,1]=b+d
```

```

⇒ G[1,2]=a+c
⇒ G[1,3]=b2+d2
⇒ G[1,4]=ab+cd
⇒ G[1,5]=a2+c2

```

See also: [Section D.7.1.6 \[invariant_algebra_perm\]](#), page 1784.

D.7.1.6 invariant_algebra_perm

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar_lib\]](#), page 1779).

- Usage:** `invariant_algebra_perm(GEN[v]);`
 GEN: a list of generators of a permutation group. It is given in disjoint cycle form, where trivial cycles can be omitted; e.g., the generator $(1,2)(3,4)(5)$ is given by `<list(list(1,2),list(3,4))>`.
 v: an optional `<int>`
- Return:** A minimal homogeneous generating set of the invariant ring of the group presented by GEN, type `<matrix>`
- Assume:** We are in the non-modular case, i.e., the characteristic of the basering does not divide the group order. Note that the function does not verify whether this assumption holds or not
- Display:** Information on the progress of computations if v does not equal 0
- Theory:** We do an incremental search in increasing degree d. Generators of the invariant ring are found among the orbit sums of degree d. The generators are chosen by Groebner basis techniques (see S. King: Minimal generating sets of non-modular invariant rings of finite groups).
- Note:** `invariant_algebra_perm` should not be used in rings with weighted orders.

Example:

```

LIB "finvar.lib";
ring R=0,(a,b,c,d),dp;
def GEN=list(list(list(1,3),list(2,4)));
matrix G = invariant_algebra_perm(GEN,1);
⇒ Searching generators in degree 1
⇒ We have 2 orbit sums of degree 1
⇒ We found generator number 1 in degree 1
⇒ We found generator number 2 in degree 1
⇒ Computing Groebner basis up to the new degree 2
⇒ Searching generators in degree 2
⇒ We have 3 orbit sums of degree 2
⇒ We found generator number 3 in degree 2
⇒ We found generator number 4 in degree 2
⇒ We found generator number 5 in degree 2
⇒ Computing Groebner basis up to the new degree 3
⇒ We found the degree bound 2
⇒ We went beyond the degree bound, so, we are done!
G;
⇒ G[1,1]=b+d
⇒ G[1,2]=a+c
⇒ G[1,3]=b2+d2
⇒ G[1,4]=ab+cd

```

$\mapsto G[1,5]=a2+c2$

See also: [Section D.7.1.5 \[invariant_algebra_reynolds\]](#), page 1783.

D.7.1.7 cyclotomic

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\]](#), page 1779).

Usage: `cyclotomic(i); i integer > 0`

Returns: the i -th cyclotomic polynomial (type `<poly>`) as one in the first ring variable

Theory: x^{i-1} is divided by the j -th cyclotomic polynomial where j takes on the value of proper divisors of i

Example:

```
LIB "finvar.lib";
ring R=0,(x,y,z),dp;
print(cyclotomic(25));
 $\mapsto x^{20}+x^{15}+x^{10}+x^5+1$ 
```

D.7.1.8 group_reynolds

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\]](#), page 1779).

Usage: `group_reynolds(G1,G2,...[,v]);`
 $G1, G2, \dots$: $n \times n$ `<matrices>` generating a finite matrix group, v : an optional `<int>`

Assume: n is the number of variables of the basering, g the number of group elements

Return: a `<list>`, the first list element will be a $g \times n$ `<matrix>` representing the Reynolds operator if we are in the non-modular case; if the characteristic is >0 , `minpoly==0` and the finite group non-cyclic the second list element is an `<int>` giving the lowest common multiple of the matrix group elements' order (used in `molien`); in general all other list elements are $n \times n$ `<matrices>` listing all elements of the finite group

Display: information if v does not equal 0

Theory: The entire matrix group is generated by getting all left products of generators with the new elements from the last run through the loop (or the generators themselves during the first run). All the ones that have been generated before are thrown out and the program terminates when no new elements found in one run. Additionally each time a new group element is found the corresponding ring mapping of which the Reynolds operator is made up is generated. They are stored in the rows of the first return value.

Example:

```
LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=group_reynolds(A);
print(L[1]);
 $\mapsto y, -x, -z,$ 
 $\mapsto -x, -y, z,$ 
 $\mapsto -y, x, -z,$ 
 $\mapsto x, y, z$ 
print(L[2..size(L)]);
 $\mapsto 0, 1, 0,$ 
```

```

⇒ -1,0,0,
⇒ 0, 0,-1
⇒ -1,0, 0,
⇒ 0, -1,0,
⇒ 0, 0, 1
⇒ 0,-1,0,
⇒ 1,0, 0,
⇒ 0,0, -1
⇒ 1,0,0,
⇒ 0,1,0,
⇒ 0,0,1

```

D.7.1.9 molien

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\]](#), page 1779).

- Usage:** `molien(G1,G2,...[,ringname,lcm,flags]);`
`G1,G2,...:` `nxn <matrices>`, all elements of a finite matrix group, `Finvar::newring:` a new ring of characteristic 0 for the Molien series in case of prime characteristic, `lcm:` an `<int>` giving the lowest common multiple of the elements' orders in case of prime characteristic, `minpoly==0` and a non-cyclic group, `flags:` an optional `<intvec>` with three components: if the first element is not equal to 0 characteristic 0 is simulated, i.e. the Molien series is computed as if the base field were characteristic 0 (the user must choose a field of large prime characteristic, e.g. 32003), the second component should give the size of intervals between canceling common factors in the expansion of the Molien series, 0 (the default) means only once after generating all terms, in prime characteristic also a negative number can be given to indicate that common factors should always be canceled when the expansion is simple (the root of the extension field does not occur among the coefficients)
- Assume:** `n` is the number of variables of the basering, `G1,G2...` are the group elements generated by `group_reynolds()`, `lcm` is the second return value of `group_reynolds()`
- Return:** in case of characteristic 0 a `1x2 <matrix>` giving enumerator and denominator of Molien series; in case of prime characteristic a ring with the name `newring` of characteristic 0 is created where the same Molien series (named `M`) is stored
- Display:** information if the third component of `flags` does not equal 0
- Theory:** In characteristic 0 the terms $1/\det(1-xE)$ for all group elements of the Molien series are computed in a straight forward way. In prime characteristic a Brauer lift is involved. The returned matrix gives enumerator and denominator of the expanded version where common factors have been canceled.

Example:

```

LIB "finvar.lib";
"      note the case of prime characteristic";
⇒      note the case of prime characteristic
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=group_reynolds(A);
matrix M=molien(L[2..size(L)]);
print(M);
⇒ x3+x2-x+1,-x7+x6+x5-x4+x3-x2-x+1

```

```

ring S=3,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=group_reynolds(A);
molien(L[2..size(L)],"");
setring Finvar::newring;
print(M);
↪ x3+x2-x+1,-x7+x6+x5-x4+x3-x2-x+1
setring S;
kill Finvar::newring;

```

D.7.1.10 reynolds_molien

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\]](#), page 1779).

- Usage:** `reynolds_molien(G1,G2,...[,ringname,flags]);`
`G1,G2,...: nxn <matrix>` generating a finite matrix group, `Finvar::newring:` a new ring of characteristic 0 for the Molien series in case of prime characteristic, `flags:` an optional `<intvec>` with three components: if the first element is not equal to 0 characteristic 0 is simulated, i.e. the Molien series is computed as if the base field were characteristic 0 (the user must choose a field of large prime characteristic, e.g. 32003) the second component should give the size of intervals between canceling common factors in the expansion of the Molien series, 0 (the default) means only once after generating all terms, in prime characteristic also a negative number can be given to indicate that common factors should always be canceled when the expansion is simple (the root of the extension field does not occur among the coefficients)
- Assume:** `n` is the number of variables of the basering, `G1,G2...` are the group elements generated by `group_reynolds()`, `g` is the size of the group
- Return:** a `gxn <matrix>` representing the Reynolds operator is the first return value and in case of characteristic 0 a `1x2 <matrix>` giving enumerator and denominator of Molien series is the second one; in case of prime characteristic a ring with the name `newring` of characteristic 0 is created where the same Molien series (named `M`) is stored
- Display:** information if the third component of `flags` does not equal 0
- Theory:** The entire matrix group is generated by getting all left products of the generators with new elements from the last run through the loop (or the generators themselves during the first run). All the ones that have been generated before are thrown out and the program terminates when are no new elements found in one run. Additionally each time a new group element is found the corresponding ring mapping of which the Reynolds operator is made up is generated. They are stored in the rows of the first return value. In characteristic 0 the terms $1/\det(1-xE)$ is computed whenever a new element `E` is found. In prime characteristic a Brauer lift is involved and the terms are only computed after the entire matrix group is generated (to avoid the modular case). The returned matrix gives enumerator and denominator of the expanded version where common factors have been canceled.

Example:

```

LIB "finvar.lib";
"      note the case of prime characteristic";
↪      note the case of prime characteristic
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;

```

```

matrix REY,M=reynolds_molien(A);
print(REY);
↪ y, -x,-z,
↪ -x,-y,z,
↪ -y,x, -z,
↪ x, y, z
print(M);
↪ x3+x2-x+1,-x7+x6+x5-x4+x3-x2-x+1
ring S=3,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
matrix REY=reynolds_molien(A,"");
print(REY);
↪ y, -x,-z,
↪ -x,-y,z,
↪ -y,x, -z,
↪ x, y, z
setring Finvar::newring;
print(M);
↪ x3+x2-x+1,-x7+x6+x5-x4+x3-x2-x+1
setring S;
kill Finvar::newring;

```

D.7.1.11 partial_molien

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\]](#), page 1779).

- Usage:** `partial_molien(M,n[p]);`
M: a 1x2 <matrix>, n: an <int> indicating number of terms in the expansion, p: an optional <poly>
- Assume:** M is the return value of `molien` or the second return value of `reynolds_molien`, p ought to be the second return value of a previous run of `partial_molien` and avoids recalculating known terms
- Return:** n terms (type <poly>) of the partial expansion of the Molien series (first n if there is no third parameter given, otherwise the next n terms depending on a previous calculation) and an intermediate result (type <poly>) of the calculation to be used as third parameter in a next run of `partial_molien`
- Theory:** The following calculation is implemented:

$$\frac{(1+a_1x+a_2x^2+\dots+anx^n)/(1+b_1x+b_2x^2+\dots+bm x^m)}{(1+b_1x+b_2x^2+\dots+bm x^m)} = (1+(a_1-b_1)x+\dots$$

$$(a_1-b_1)x+(a_2-b_2)x^2+\dots$$

$$(a_1-b_1)x+b_1(a_1-b_1)x^2+\dots$$

Example:

```

LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
matrix REY,M=reynolds_molien(A);
poly p(1..2);
p(1..2)=partial_molien(M,5);
p(1);
↪ 4x5+5x4+2x3+2x2+1

```

```

p(1..2)=partial_molien(M,5,p(2));
p(1);
↦ 18x10+12x9+13x8+8x7+8x6

```

D.7.1.12 evaluate_reynolds

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `evaluate_reynolds(REY,I);`
 REY: a <matrix> representing the Reynolds operator, I: an arbitrary <ideal>
- Assume:** REY is the first return value of `group_reynolds()` or `reynolds_molien()`
- Returns:** image of the polynomials defining I under the Reynolds operator (type <ideal>)
- Note:** the characteristic of the coefficient field of the polynomial ring should not divide the order of the finite matrix group
- Theory:** REY has been constructed in such a way that each row serves as a ring mapping of which the Reynolds operator is made up.

Example:

```

LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=group_reynolds(A);
ideal I=x2,y2,z2;
print(evaluate_reynolds(L[1],I));
↦ 1/2x2+1/2y2,
↦ 1/2x2+1/2y2,
↦ z2

```

D.7.1.13 invariant_basis

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `invariant_basis(g,G1,G2,...);`
 g: an <int> indicating of which degree (>0) the homogeneous basis should be, G1,G2,...: <matrices> generating a finite matrix group
- Returns:** the basis (type <ideal>) of the space of invariants of degree g
- Theory:** A general polynomial of degree g is generated and the generators of the matrix group applied. The difference ought to be 0 and this way a system of linear equations is created. It is solved by computing syzygies.

Example:

```

LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
print(invariant_basis(2,A));
↦ x2+y2,
↦ z2

```

D.7.1.14 invariant_basis_reynolds

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `invariant_basis_reynolds(REY,d[,flags]);`
 REY: a <matrix> representing the Reynolds operator, d: an <int> indicating of which degree (>0) the homogeneous basis should be, flags: an optional <intvec> with two entries: its first component gives the dimension of the space (default <0 meaning unknown) and its second component is used as the number of polynomials that should be mapped to invariants during one call of `evaluate_reynolds` if the dimension of the space is unknown or the number such that number x dimension polynomials are mapped to invariants during one call of `evaluate_reynolds`
- Assume:** REY is the first return value of `group_reynolds()` or `reynolds_molien()` and flags[1] given by `partial_molien`
- Return:** the basis (type <ideal>) of the space of invariants of degree d
- Theory:** Monomials of degree d are mapped to invariants with the Reynolds operator. A linearly independent set is generated with the help of `minbase`.

Example:

```
LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
intvec flags=0,1,0;
matrix REY,M=reynolds_molien(A,flags);
flags=8,6;
print(invariant_basis_reynolds(REY,6,flags));
⇒ z6,
⇒ x2z4+y2z4,
⇒ x2y2z2,
⇒ x3yz2-xy3z2,
⇒ x4z2+y4z2,
⇒ x4y2+x2y4,
⇒ x5y-xy5,
⇒ x6+y6
```

D.7.1.15 primary_char0

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `primary_char0(REY,M[,v]);`
 REY: a <matrix> representing the Reynolds operator, M: a 1x2 <matrix> representing the Molien series, v: an optional <int>
- Assume:** REY is the first return value of `group_reynolds` or `reynolds_molien` and M the one of `molien` or the second one of `reynolds_molien`
- Display:** information about the various stages of the programme if v does not equal 0
- Return:** primary invariants (type <matrix>) of the invariant ring
- Theory:** Bases of homogeneous invariants are generated successively and those are chosen as primary invariants that lower the dimension of the ideal generated by the previously found invariants (see paper "Generating a Noetherian Normalization of the Invariant Ring of a Finite Group" by Decker, Heydtmann, Schreyer (1998)).

Example:

```
LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
matrix REY,M=reynolds_molien(A);
matrix P=primary_char0(REY,M);
print(P);
↦ z2,x2+y2,x2y2
```

D.7.1.16 primary_charp

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `primary_charp(REY,ringname[,v]);`
 REY: a <matrix> representing the Reynolds operator,
 Finvar::newring: the ring where the Molien series is stored, v: an optional <int>
- Assume:** REY is the first return value of `group_reynolds` or `reynolds_molien` and `ringname` gives the name of a ring of characteristic 0 that has been created by `molien` or `reynolds_molien`
- Display:** information about the various stages of the programme if v does not equal 0
- Return:** primary invariants (type <matrix>) of the invariant ring
- Theory:** Bases of homogeneous invariants are generated successively and those are chosen as primary invariants that lower the dimension of the ideal generated by the previously found invariants (see paper "Generating a Noetherian Normalization of the Invariant Ring of a Finite Group" by Decker, Heydtmann, Schreyer (1998)).

Example:

```
LIB "finvar.lib";
ring R=3,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=group_reynolds(A);
molien(L[2..size(L)], "");
matrix P=primary_charp(L[1], "");
kill Finvar::newring;
print(P);
↦ z2,x2+y2,x2y2
```

D.7.1.17 primary_char0_no_molien

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `primary_char0_no_molien(REY[,v]);`
 REY: a <matrix> representing the Reynolds operator, v: an optional <int>
- Assume:** REY is the first return value of `group_reynolds` or `reynolds_molien`
- Display:** information about the various stages of the programme if v does not equal 0
- Return:** primary invariants (type <matrix>) of the invariant ring and an <intvec> listing some of the degrees where no non-trivial homogeneous invariants are to be found
- Theory:** Bases of homogeneous invariants are generated successively and those are chosen as primary invariants that lower the dimension of the ideal generated by the previously found invariants (see paper "Generating a Noetherian Normalization of the Invariant Ring of a Finite Group" by Decker, Heydtmann, Schreyer (1998)).

Example:

```
LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=group_reynolds(A);
list l=primary_char0_no_molien(L[1]);
print(l[1]);
↦ z2,x2+y2,x2y2
```

D.7.1.18 primary_charp_no_molien

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `primary_charp_no_molien(REY[,v]);`
 REY: a <matrix> representing the Reynolds operator, v: an optional <int>
- Assume:** REY is the first return value of `group_reynolds` or `reynolds_molien`
- Display:** information about the various stages of the programme if v does not equal 0
- Return:** primary invariants (type <matrix>) of the invariant ring and an <intvec> listing some of the degrees where no non-trivial homogeneous invariants are to be found
- Theory:** Bases of homogeneous invariants are generated successively and those are chosen as primary invariants that lower the dimension of the ideal generated by the previously found invariants (see paper "Generating a Noetherian Normalization of the Invariant Ring of a Finite Group" by Decker, Heydtmann, Schreyer (1998)).

Example:

```
LIB "finvar.lib";
ring R=3,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=group_reynolds(A);
list l=primary_charp_no_molien(L[1]);
print(l[1]);
↦ z2,x2+y2,x2y2
```

D.7.1.19 primary_charp_without

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `primary_charp_without(G1,G2,...[,v]);`
 G1,G2,...: <matrices> generating a finite matrix group, v: an optional <int>
- Display:** information about the various stages of the programme if v does not equal 0
- Return:** primary invariants (type <matrix>) of the invariant ring
- Theory:** Bases of homogeneous invariants are generated successively and those are chosen as primary invariants that lower the dimension of the ideal generated by the previously found invariants (see paper "Generating a Noetherian Normalization of the Invariant Ring of a Finite Group" by Decker, Heydtmann, Schreyer (1998)). No Reynolds operator or Molien series is used.

Example:

```
LIB "finvar.lib";
ring R=2,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
matrix P=primary_charp_without(A);
print(P);
↦ x+y,z,xy
```

D.7.1.20 primary_char0_random

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `primary_char0_random(REY,M,r[v]);`
 REY: a <matrix> representing the Reynolds operator, M: a 1x2 <matrix> representing the Molien series, r: an <int> where $-|r|$ to $|r|$ is the range of coefficients of the random combinations of bases elements, v: an optional <int>
- Assume:** REY is the first return value of `group_reynolds` or `reynolds_molien` and M the one of `molien` or the second one of `reynolds_molien`
- Display:** information about the various stages of the programme if v does not equal 0
- Return:** primary invariants (type <matrix>) of the invariant ring
- Theory:** Bases of homogeneous invariants are generated successively and random linear combinations are chosen as primary invariants that lower the dimension of the ideal generated by the previously found invariants (see "Generating a Noetherian Normalization of the Invariant Ring of a Finite Group" by Decker, Heydtmann, Schreyer (1998)).

Example:

```
LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
matrix REY,M=reynolds_molien(A);
matrix P=primary_char0_random(REY,M,1);
print(P);
↦ z2,x2+y2,x4+y4-z4
```

D.7.1.21 primary_charp_random

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `primary_charp_random(REY,ringname,r[v]);`
 REY: a <matrix> representing the Reynolds operator,
 Finvar::newring: the ring where the Molien series is stored, r: an <int> where $-|r|$ to $|r|$ is the range of coefficients of the random combinations of bases elements, v: an optional <int>
- Assume:** REY is the first return value of `group_reynolds` or `reynolds_molien` and ringname gives the name of a ring of characteristic 0 that has been created by `molien` or `reynolds_molien`
- Display:** information about the various stages of the programme if v does not equal 0
- Return:** primary invariants (type <matrix>) of the invariant ring
- Theory:** Bases of homogeneous invariants are generated successively and random linear combinations are chosen as primary invariants that lower the dimension of the ideal generated by the previously found invariants (see "Generating a Noetherian Normalization of the Invariant Ring of a Finite Group" by Decker, Heydtmann, Schreyer (1998)).

Example:

```

LIB "finvar.lib";
ring R=3,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=group_reynolds(A);
molien(L[2..size(L)], "");
matrix P=primary_charp_random(L[1], "", 1);
kill Finvar::newring;
print(P);
↦ z2,x2+y2,x4+y4-z4

```

D.7.1.22 primary_char0_no_molien_random

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `primary_char0_no_molien_random(REY,r[,v]);`
 REY: a <matrix> representing the Reynolds operator, r: an <int> where $-|r|$ to $|r|$ is the range of coefficients of the random combinations of bases elements, v: an optional <int>
- Assume:** REY is the first return value of `group_reynolds` or `reynolds_molien`
- Display:** information about the various stages of the programme if v does not equal 0
- Return:** primary invariants (type <matrix>) of the invariant ring and an <intvec> listing some of the degrees where no non-trivial homogeneous invariants are to be found
- Theory:** Bases of homogeneous invariants are generated successively and random linear combinations are chosen as primary invariants that lower the dimension of the ideal generated by the previously found invariants (see "Generating a Noetherian Normalization of the Invariant Ring of a Finite Group" by Decker, Heydtmann, Schreyer (1998)).

Example:

```

LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=group_reynolds(A);
list l=primary_char0_no_molien_random(L[1],1);
print(l[1]);
↦ z2,x2+y2,x4+y4-z4

```

D.7.1.23 primary_charp_no_molien_random

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `primary_charp_no_molien_random(REY,r[,v]);`
 REY: a <matrix> representing the Reynolds operator, r: an <int> where $-|r|$ to $|r|$ is the range of coefficients of the random combinations of bases elements, v: an optional <int>
- Assume:** REY is the first return value of `group_reynolds` or `reynolds_molien`
- Display:** information about the various stages of the programme if v does not equal 0
- Return:** primary invariants (type <matrix>) of the invariant ring and an <intvec> listing some of the degrees where no non-trivial homogeneous invariants are to be found

Theory: Bases of homogeneous invariants are generated successively and random linear combinations are chosen as primary invariants that lower the dimension of the ideal generated by the previously found invariants (see "Generating a Noetherian Normalization of the Invariant Ring of a Finite Group" by Decker, Heydtmann, Schreyer (1998)).

Example:

```
LIB "finvar.lib";
ring R=3,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=group_reynolds(A);
list l=primary_charp_no_molien_random(L[1],1);
print(l[1]);
↦ z2,x2+y2,x4+y4-z4
```

D.7.1.24 primary_charp_without_random

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

Usage: `primary_charp_without_random(G1,G2,...,r[v]);`
`G1,G2,...:` <matrices> generating a finite matrix group, `r:` an <int> where $-|r|$ to $|r|$ is the range of coefficients of the random combinations of bases elements, `v:` an optional <int>

Display: information about the various stages of the programme if `v` does not equal 0

Return: primary invariants (type <matrix>) of the invariant ring

Theory: Bases of homogeneous invariants are generated successively and random linear combinations are chosen as primary invariants that lower the dimension of the ideal generated by the previously found invariants (see "Generating a Noetherian Normalization of the Invariant Ring of a Finite Group" by Decker, Heydtmann, Schreyer (1998)). No Reynolds operator or Molien series is used.

Example:

```
LIB "finvar.lib";
ring R=2,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
matrix P=primary_charp_without_random(A,1);
print(P);
↦ x+y,z,xy
```

D.7.1.25 power_products

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

Usage: `power_products(dv,d);`
`dv:` an <intvec> giving the degrees of homogeneous polynomials, `d:` the degree of the desired power products

Return: a $\text{size}(dv)*m$ <intmat> where each column ought to be interpreted as containing the exponents of the corresponding polynomials. The product of the powers is then homogeneous of degree `d`.

Example:

```

LIB "finvar.lib";
intvec dv=5,5,5,10,10;
print(power_products(dv,10));
↳      2      1      1      0      0      0      0      0
↳      0      1      0      2      1      0      0      0
↳      0      0      1      0      1      2      0      0
↳      0      0      0      0      0      0      1      0
↳      0      0      0      0      0      0      0      1
print(power_products(dv,7));
↳      0
↳      0
↳      0
↳      0
↳      0

```

D.7.1.26 secondary_char0

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\]](#), page 1779).

- Usage:** `secondary_char0(P,REY,M[,v][,"old"]);`
P: a $1 \times n$ <matrix> with homogeneous primary invariants, where n is the number of variables of the basering;
REY: a $g \times n$ <matrix> representing the Reynolds operator, where g the size of the corresponding group;
M: a 1×2 <matrix> giving numerator and denominator of the Molien series;
v: an optional <int>;
"old": if this string occurs as (optional) parameter, then an old version of `secondary_char0` is used (for downward compatibility)
- Assume:** The characteristic of basering is zero;
REY is the 1st return value of `group_reynolds()`, `reynolds_molien()` or the second one of `primary_invariants()`;
M is the return value of `molien()` or the second one of `reynolds_molien()` or the third one of `primary_invariants()`
- Return:** Homogeneous secondary invariants and irreducible secondary invariants of the invariant ring (both type <matrix>)
- Display:** Information on the progress of the computations if v is an integer different from 0.
- Theory:** The secondary invariants are calculated by finding a basis (in terms of monomials) of the basering modulo the primary invariants, mapping those to invariants with the Reynolds operator. Among these images or their power products we pick secondary invariants using Groebner basis techniques (see S. King: Fast Computation of Secondary Invariants).
The size of this set can be read off from the Molien series.
- Note:** Secondary invariants are not uniquely determined by the given data. Specifically, the output of `secondary_char0(P,REY,M,"old")` will differ from the output of `secondary_char0(P,REY,M)`. However, the ideal generated by the irreducible homogeneous secondary invariants will be the same in both cases.
There are three internal parameters "pieces", "MonStep" and "IrrSwitch". The default values of the parameters should be fine in most cases. However, in some cases,

different values may provide a better balance of memory consumption (smaller values) and speed (bigger values).

Example:

```
LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=primary_invariants(A);
matrix S,IS=secondary_char0(L[1..3],1);
↳
↳ We need to find
↳ 1 secondary invariant in degree 0
↳ 0 secondary invariants in degree 1
↳ 0 secondary invariants in degree 2
↳ 2 secondary invariants in degree 3
↳ 1 secondary invariant in degree 4
↳ In degree 0 we have: 1
↳
↳ Searching in degree 3 , we need to find 2 invariant(s)...
↳ Looking for Power Products...
↳ There are 2 irreducible secondary invariants in degree 3
↳ We found all 2 irreducibles in degree 3
↳
↳ Searching in degree 4 , we need to find 1 invariant(s)...
↳ Looking for Power Products...
↳ There are 1 irreducible secondary invariants in degree 4
↳ We found all 1 irreducibles in degree 4
↳
↳ We're done!
↳
print(S);
↳ 1,xyz,x2z-y2z,x3y-xy3
print(IS);
↳ xyz,x2z-y2z,x3y-xy3
```

See also: [Section D.7.1.27 \[irred_secondary_char0\]](#), page 1797.

D.7.1.27 irred_secondary_char0

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\]](#), page 1779).

Usage: `irred_secondary_char0(P,REY,M[,v][,"PP"])`;
P: a $1 \times n$ <matrix> with homogeneous primary invariants, where n is the number of variables of the basering;
REY: a $g \times n$ <matrix> representing the Reynolds operator, where g the size of the corresponding group;
M: a 1×2 <matrix> giving numerator and denominator of the Molien series;
v: an optional <int>;
"PP": if this string occurs as (optional) parameter, then in all degrees power products of irr. sec. inv. will be computed.

Return: Irreducible homogeneous secondary invariants of the invariant ring (type <matrix>)

Assume: We are in the non-modular case, i.e., the characteristic of the basering does not divide the group order;

Usage: `secondary_charp(P,REY,ringname[v][,"old"]);`
P: a 1xn <matrix> with homogeneous primary invariants, where n is the number of variables of the basering;
REY: a gxn <matrix> representing the Reynolds operator, where g the size of the corresponding group;
Finvar::newring is the ring of characteristic 0 containing a 1x2 <matrix> M giving numerator and denominator of the Molien series;
v: an optional <int>;

"old": if this string occurs as (optional) parameter, then an old version of secondary_char0 is used (for downward compatibility)

- Assume:** The characteristic of basering is not zero;
 REY is the 1st return value of group_reynolds(), reynolds_molien() or the second one of primary_invariants();
 Finvar::newring is the ring of characteristic 0 that has been created by molien() or reynolds_molien() or primary_invariants()
- Return:** secondary invariants of the invariant ring (type <matrix>) and irreducible secondary invariants (type <matrix>)
- Display:** information if v does not equal 0
- Theory:** The secondary invariants are calculated by finding a basis (in terms of monomials) of the basering modulo the primary invariants, mapping those to invariants with the Reynolds operator. Among these images or their power products we pick secondary invariants using Groebner basis techniques (see S. King: Fast Computation of Secondary Invariants). The size of this set can be read off from the Molien series.

Example:

```
LIB "finvar.lib";
ring R=3,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=primary_invariants(A);
matrix S,IS=secondary_charp(L[1..size(L)],1);
⇒
⇒ We need to find
⇒ 1 secondary invariant in degree 0
⇒ 0 secondary invariants in degree 1
⇒ 0 secondary invariants in degree 2
⇒ 2 secondary invariants in degree 3
⇒ 1 secondary invariant in degree 4
⇒ In degree 0 we have: 1
⇒
⇒ Searching in degree 3 , we need to find 2 invariant(s)...
⇒ Looking for Power Products...
⇒ There are 2 irreducible secondary invariants in degree 3
⇒ We found all 2 irreducibles in degree 3
⇒
⇒ Searching in degree 4 , we need to find 1 invariant(s)...
⇒ Looking for Power Products...
⇒ There are 1 irreducible secondary invariants in degree 4
⇒ We found all 1 irreducibles in degree 4
⇒
⇒ We're done!
⇒
print(S);
⇒ 1,xyz,x2z-y2z,x3y-xy3
print(IS);
⇒ xyz,x2z-y2z,x3y-xy3
```

D.7.1.29 secondary_no_molien

Procedure from library finvar.lib (see [Section D.7.1 \[finvar.lib\]](#), page 1779).

- Usage:** `secondary_no_molien(P,REY[,deg_vec,v]);`
P: a $1 \times n$ <matrix> with primary invariants, REY: a $g \times n$ <matrix> representing the Reynolds operator, deg_vec: an optional <intvec> listing some degrees where no non-trivial homogeneous invariants can be found, v: an optional <int>
- Assume:** n is the number of variables of the basering, g the size of the group, REY is the 1st return value of `group_reynolds()`, `reynolds_molien()` or the second one of `primary_invariants()`, deg_vec is the second return value of `primary_char0_no_molien()`, `primary_charp_no_molien()`, `primary_char0_no_molien_random()` or `primary_charp_no_molien_random()`
- Return:** secondary invariants of the invariant ring (type <matrix>)
- Display:** information if v does not equal 0
- Theory:** Secondary invariants are calculated by finding a basis (in terms of monomials) of the basering modulo primary invariants, mapping those to invariants with the Reynolds operator and using these images as candidates for secondary invariants. We have the Reynolds operator, hence, we are in the non-modular case. Therefore, the invariant ring is Cohen-Macaulay, hence the number of secondary invariants is the product of the degrees of primary invariants divided by the group order.
- Note:** <secondary_and_irreducibles_no_molien> should usually be faster and of more useful functionality.

Example:

```
LIB "finvar.lib";
ring R=3,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=primary_invariants(A,intvec(1,1,0));
// In that example, there are no secondary invariants
// in degree 1 or 2.
matrix S=secondary_no_molien(L[1..2],intvec(1,2),1);
⇒ We need to find 4 secondary invariants.
⇒
⇒ In degree 0 we have: 1
⇒
⇒ Searching in degree 3 ...
⇒ We found sec. inv. number 2 in degree 3
⇒ We found sec. inv. number 3 in degree 3
⇒ Searching in degree 4 ...
⇒ We found sec. inv. number 4 in degree 4
⇒
⇒ We're done!
⇒
print(S);
⇒ 1,xyz,x2z-y2z,x3y-xy3
```

See also: [Section D.7.1.31 \[secondary_and_irreducibles_no_molien\]](#), page 1801.

D.7.1.30 irred_secondary_no_molien

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\]](#), page 1779).

- Usage:** `irred_secondary_no_molien(P,REY[,deg_vec,v]);`
P: a $1 \times n$ <matrix> with primary invariants, REY: a $g \times n$ <matrix> representing the

Reynolds operator, deg_vec: an optional <intvec> listing some degrees where no irreducible secondary invariants can be found, v: an optional <int>

Assume: n is the number of variables of the basering, g the size of the group, REY is the 1st return value of group_reynolds(), reynolds_molien() or the second one of primary_invariants()

Return: Irreducible secondary invariants of the invariant ring (type <matrix>)

Display: information if v does not equal 0

Theory: Irred. secondary invariants are calculated by finding a basis (in terms of monomials) of the basering modulo primary and previously found secondary invariants, mapping those to invariants with the Reynolds operator. Among these images we pick secondary invariants, using Groebner basis techniques.

Example:

```
LIB "finvar.lib";
ring R=3,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=primary_invariants(A,intvec(1,1,0));
// In that example, there are no secondary invariants
// in degree 1 or 2.
matrix IS=irred_secondary_no_molien(L[1..2],intvec(1,2),1);
↳
↳ Searching irred. sec. inv. in degree 3
↳ We have 4 candidates for irred. secondaries
↳ We found irr. sec. inv. number 1 in degree 3
↳ We found irr. sec. inv. number 2 in degree 3
↳ Searching irred. sec. inv. in degree 4
↳ We have 1 candidates for irred. secondaries
↳ We found irr. sec. inv. number 3 in degree 4
↳ Searching irred. sec. inv. in degree 5
↳ Searching irred. sec. inv. in degree 6
↳ Searching irred. sec. inv. in degree 7

See also: [Section D.7.1.27 \[irred_secondary_char0\]](#), page 1797.

D.7.1.31 secondary_and_irreducibles_no_molien

Procedure from library finvar.lib (see [Section D.7.1 \[finvar_lib\]](#), page 1779).

Usage: secondary_and_irreducibles_no_molien(P,REY[,deg_vec,v]); P: a 1xn <matrix> with primary invariants, REY: a gxn <matrix> representing the Reynolds operator, deg_vec: an optional <intvec> listing some degrees where no non-trivial homogeneous invariants can be found, v: an optional <int>

Assume: n is the number of variables of the basering, g the size of the group, REY is the 1st return value of group_reynolds(), reynolds_molien() or the second one of primary_invariants()

- Return:** secondary invariants of the invariant ring (type <matrix>) and irreducible secondary invariants (type <matrix>)
- Display:** information if v does not equal 0
- Theory:** Secondary invariants are calculated by finding a basis (in terms of monomials) of the basering modulo primary invariants, mapping those to invariants with the Reynolds operator. Among these images or their power products we pick secondary invariants using Groebner basis techniques (see S. King: Fast Computation of Secondary Invariants). We have the Reynolds operator, hence, we are in the non-modular case. Therefore, the invariant ring is Cohen-Macaulay, hence the number of secondary invariants is the product of the degrees of primary invariants divided by the group order.

Example:

```
LIB "finvar.lib";
ring R=3,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=primary_invariants(A,intvec(1,1,0));
// In that example, there are no secondary invariants
// in degree 1 or 2.
matrix S,IS=secondary_and_irreducibles_no_molien(L[1..2],intvec(1,2),1);
⇒
⇒ We need to find 4 secondary invariants.
⇒
⇒ In degree 0 we have: 1
⇒
⇒ Searching in degree 3
⇒ Looking for Power Products...
⇒ Looking for irreducible secondary invariants in degree 3
⇒ We found irreducible sec. inv. number 1 in degree 3
⇒ We found irreducible sec. inv. number 2 in degree 3
⇒
⇒ Searching in degree 4
⇒ Looking for Power Products...
⇒ Looking for irreducible secondary invariants in degree 4
⇒ We found irreducible sec. inv. number 1 in degree 4
⇒
⇒
⇒ We're done!
⇒
print(S);
⇒ 1,xyz,x2z-y2z,x3y-xy3
print(IS);
⇒ xyz,x2z-y2z,x3y-xy3
```

See also: [Section D.7.1.29 \[secondary_no_molien\]](#), page 1799.

D.7.1.32 secondary_not_cohen_macaulay

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar_lib\]](#), page 1779).

- Usage:** `secondary_not_cohen_macaulay(P,G1,G2,...[,v]);`
P: a 1xn <matrix> with primary invariants, G1,G2,...: nxn <matrices> generating a finite matrix group, v: optional <int>
- Assume:** n is the number of variables of the basering

- Return:** secondary invariants of the invariant ring (type <matrix>)
- Display:** information on the progress of computation if v does not equal 0
- Theory:** Secondary invariants are generated following "Generating Invariant Rings of Finite Groups over Arbitrary Fields" by Kemper (1996).

Example:

```
LIB "finvar.lib";
ring R=2,(x,y,z),dp;
matrix A[3][3]=0,1,0,-1,0,0,0,0,-1;
list L=primary_invariants(A);
matrix S=secondary_not_cohen_macaulay(L[1],A);
print(S);
⇒ 1
```

D.7.1.33 orbit_variety

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `orbit_variety(F,s);`
F: a 1xm <matrix> defining an invariant ring, s: a <string> giving the name for a new ring
- Return:** a Groebner basis (type <ideal>, named G) for the ideal defining the orbit variety (i.e. the syzygy ideal) in the new ring (named newring)
- Theory:** The ideal of algebraic relations of the invariant ring generators is calculated, then the variables of the original ring are eliminated and the polynomials that are left over define the orbit variety

Example:

```
LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix F[1][7]=x2+y2,z2,x4+y4,1,x2z-1y2z,xyz,x3y-1xy3;
orbit_variety(F,"");
print(G);
⇒ y(4)-1,
⇒ y(5)*y(6)-y(2)*y(7),
⇒ y(2)*y(3)-y(5)^2-2*y(6)^2,
⇒ y(1)^2*y(6)-2*y(3)*y(6)+y(5)*y(7),
⇒ y(1)^2*y(5)-y(3)*y(5)-2*y(6)*y(7),
⇒ y(1)^2*y(2)-y(2)*y(3)-2*y(6)^2,
⇒ y(1)^4-3*y(1)^2*y(3)+2*y(3)^2+2*y(7)^2
basing;
⇒ // coefficients: QQ
⇒ // number of vars : 7
⇒ //          block 1 : ordering dp
⇒ //          : names y(1) y(2) y(3) y(4) y(5) y(6) y(7)
⇒ //          block 2 : ordering C
```

D.7.1.34 rel_orbit_variety

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\], page 1779](#)).

- Usage:** `rel_orbit_variety(I,F[,s]);`
 I: an <ideal> invariant under the action of a group,
 F: a 1xm <matrix> defining the invariant ring of this group.
 s: optional <string>; if s is present then (for downward compatibility) the old procedure <relative_orbit_variety> is called, and in this case s gives the name of a new <ring>.
- Return:** Without optional string s, a list L of two rings is returned.
 The ring L[1] carries a weighted degree order with variables $y(1..m)$, the weight of $y(k)$ equal to the degree of the k-th generators $F[1,k]$ of the invariant ring.
 L[1] contains a Groebner basis (type <ideal>, named G) of the ideal defining the relative orbit variety with respect to I.
 The ring L[2] has the variables of the basering together with $y(1..m)$ and carries a block order: The first block is the order of the basering, the second is the weighted degree order occurring in L[1]. L[2] contains G and a Groebner basis (type <ideal>, named Conv) such that if p is any invariant polynomial expressed in the variables of the basering then `reduce(p,Conv)` is a polynomial in the new variables $y(1..m)$ such that evaluation at the generators of the invariant ring yields p. This can be used to avoid the application of <algebra_containment> (see [Section D.4.2.1 \[algebra_containment\]](#), page 1005).
 For the case of optional string s, the function is equivalent to [Section D.7.1.35 \[relative_orbit_variety\]](#), page 1805.
- Theory:** A Groebner basis of the ideal of algebraic relations of the invariant ring generators is calculated, then one of the basis elements plus the ideal generators. The variables of the original ring are eliminated and the polynomials that are left define the relative orbit variety with respect to I. The elimination is done by a weighted blockorder that has the advantage of dealing with quasi-homogeneous ideals.
- Note:** We provide the ring L[1] for the sake of downward compatibility, since it is closer to the ring returned by `relative_orbit_variety` than L[2]. However, L[1] carries a weighted degree order, whereas the ring returned by `relative_orbit_variety` is lexicographically ordered.

Example:

```
LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix F[1][3]=x+y+z,xy+xz+yz,xyz;
ideal I=x2+y2+z2-1,x2y+y2z+z2x-2x-2y-2z,xy2+yz2+zx2-2x-2y-2z;
list L = rel_orbit_variety(I,F);
↳
↳ // 'rel_orbit_variety' created a list of two rings.
↳ // If L is the name of that list, you can access
↳ // the first ring by
↳ //   def R = L[1]; setring R;
↳ // (similarly for the second ring)
def AllR = L[2];
setring(AllR);
print(G);
↳ y(1)^2-2*y(2)-1,
↳ y(1)*y(2)-3*y(3)-4*y(1),
↳ 2*y(2)^2-3*y(1)*y(3)-7*y(2)-4,
↳ 6*y(3)^2-15*y(1)*y(3)+25*y(2)+12
print(Conv);
↳ x+y+z-y(1),
```

```

⇒ y^2+y*z+z^2-y*y(1)-z*y(1)+y(2),
⇒ z^3-z^2*y(1)+z*y(2)-y(3)
basing;
⇒ // coefficients: QQ
⇒ // number of vars : 6
⇒ //      block 1 : ordering dp
⇒ //      : names  x y z
⇒ //      block 2 : ordering wp
⇒ //      : names  y(1) y(2) y(3)
⇒ //      : weights 1 2 3
⇒ //      block 3 : ordering C

```

See also: [Section D.7.1.35 \[relative_orbit_variety\]](#), page 1805.

D.7.1.35 relative_orbit_variety

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\]](#), page 1779).

- Usage:** `relative_orbit_variety(I,F,s);`
 I: an <ideal> invariant under the action of a group,
 F: a 1xm <matrix> defining the invariant ring of this group,
 Finvar::newring: the new ring
- Return:** The procedure ends with a new ring named `newring`.
 It contains a Groebner basis
 (type <ideal>, named G) for the ideal defining the
 relative orbit variety with respect to I in the new ring.
- Theory:** A Groebner basis of the ideal of algebraic relations of the invariant ring generators is calculated, then one of the basis elements plus the ideal generators. The variables of the original ring are eliminated and the polynomials that are left define the relative orbit variety with respect to I.
- Note:** This procedure is now replaced by `rel_orbit_variety` (see [Section D.7.1.34 \[rel_orbit_variety\]](#), page 1803), which uses a different elimination order that should usually allow faster computations.

Example:

```

LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix F[1][3]=x+y+z,xy+xz+yz,xyz;
ideal I=x2+y2+z2-1,x2y+y2z+z2x-2x-2y-2z,xy2+yz2+zx2-2x-2y-2z;
string newring="E";
relative_orbit_variety(I,F,newring);
print(G);
⇒ 27*y(3)^6-513*y(3)^4+33849*y(3)^2-784,
⇒ 1475*y(2)+9*y(3)^4-264*y(3)^2+736,
⇒ 8260*y(1)+9*y(3)^5-87*y(3)^3+5515*y(3)
basing;
⇒ // coefficients: QQ
⇒ // number of vars : 3
⇒ //      block 1 : ordering lp
⇒ //      : names  y(1) y(2) y(3)
⇒ //      block 2 : ordering C

```

See also: [Section D.7.1.34 \[rel_orbit_variety\]](#), page 1803.

D.7.1.36 image_of_variety

Procedure from library `finvar.lib` (see [Section D.7.1 \[finvar.lib\]](#), page 1779).

- Usage:** `image_of_variety(I,F);`
 I: an arbitrary <ideal>,
 F: a 1xm <matrix> defining an invariant ring of some matrix group
- Return:** The <ideal> defining the image under that group of the variety defined by I
- Theory:** `rel_orbit_variety(I,F)` is called and the newly introduced variables in the output are replaced by the generators of the invariant ring. This ideal in the original variables defines the image of the variety defined by I

Example:

```
LIB "finvar.lib";
ring R=0,(x,y,z),dp;
matrix F[1][3]=x+y+z,xy+xz+yz,xyz;
ideal I=xy;
print(image_of_variety(I,F));
↦ xyz
```

D.7.2 ainvar.lib

- Library:** `ainvar.lib`
- Purpose:** Invariant Rings of the Additive Group
- Authors:** Gerhard Pfister (email: pfister@mathematik.uni-kl.de), Gert-Martin Greuel (email: greuel@mathematik.uni-kl.de)

Procedures:

D.7.2.1 invariantRing

Procedure from library `ainvar.lib` (see [Section D.7.2 \[ainvar.lib\]](#), page 1806).

- Usage:** `invariantRing(m,p,q,b[r,pa]);` m matrix, p,q poly, b,r int, pa string
- Assume:** p,q variables with $m(p)=q$ and q invariant under m
 i.e. if $p=x(i)$ and $q=x(j)$ then $m[j,1]=0$ and $m[i,1]=x(j)$
- Return:** ideal, containing generators of the ring of invariants of the additive group $(K,+)$ given by the vector field
- $$m = m[1,1]*d/dx(1) + \dots + m[n,1]*d/dx(n).$$
- If $b>0$ the computation stops after all invariants of degree $\leq b$ (and at least one of higher degree) are found or when all invariants are computed.
 If $b\leq 0$, the computation continues until all generators of the ring of invariants are computed (should be used only if the ring of invariants is known to be finitely generated, otherwise the algorithm might not stop).
 If $r=1$ a different reduction is used which is sometimes faster (default $r=0$).
- Display:** if pa is given (any string as 5th or 6th argument), the computation pauses whenever new invariants are found and displays them

Theory: The algorithm for computing the ring of invariants works in char 0 or sufficiently large characteristic.
 $(K,+)$ acts as the exponential of the vector field defined by the matrix m .
 For background see G.-M. Greuel, G. Pfister,
 Geometric quotients of unipotent group actions, Proc. London Math. Soc. (3) 67,
 75-105 (1993).

Example:

```
LIB "ainvar.lib";
//Winkelmann: free action but Spec(k[x(1),...,x(5)]) --> Spec(invariant ring)
//is not surjective
ring rw=0,(x(1..5)),dp;
matrix m[5][1];
m[3,1]=x(1);
m[4,1]=x(2);
m[5,1]=1+x(1)*x(4)+x(2)*x(3);
ideal in=invariantRing(m,x(3),x(1),0);      //compute full invariant ring
in;
in[1]=x(1)
in[2]=x(2)
in[3]=x(2)*x(3)*x(4)-x(2)*x(5)+x(4)
in[4]=x(1)*x(3)*x(4)-x(1)*x(5)+x(3)
//Deveney/Finston: The ring of invariants is not finitely generated
ring rf=0,(x(1..7)),dp;
matrix m[7][1];
m[4,1]=x(1)^3;
m[5,1]=x(2)^3;
m[6,1]=x(3)^3;
m[7,1]=(x(1)*x(2)*x(3))^2;
ideal in=invariantRing(m,x(4),x(1),6);      //all invariants up to degree 6
in;
in[1]=x(1)
in[2]=x(3)
in[3]=x(2)
in[4]=x(3)^3*x(4)-x(1)^3*x(6)
in[5]=x(2)^3*x(4)-x(1)^3*x(5)
in[6]=x(2)^2*x(3)^2*x(4)-x(1)*x(7)
in[7]=x(1)^2*x(2)^2*x(6)-x(3)*x(7)
in[8]=x(1)^2*x(3)^2*x(5)-x(2)*x(7)
in[9]=x(1)^2*x(2)*x(3)^4*x(4)*x(5)+x(1)^2*x(2)^4*x(3)*x(4)*x(6)-x(1)^5*x(
2)*x(3)*x(5)*x(6)-2*x(2)^2*x(3)^2*x(4)*x(7)+x(1)*x(7)^2
```

D.7.2.2 derivate

Procedure from library `ainvar.lib` (see [Section D.7.2 \[ainvar.lib\]](#), page 1806).

Usage: `derivate(m,id)`; m matrix, id poly/vector/ideal

Assume: m is an $n \times 1$ matrix, where n = number of variables of the basering

Return: poly/vector/ideal (same type as input), result of applying the vector field by the matrix m componentwise to id ;

Note: the vector field is $m[1,1]*d/dx(1) + \dots + m[1,n]*d/dx(n)$

Example:

```

LIB "ainvar.lib";
ring q=0,(x,y,z,u,v,w),dp;
poly f=2xz-y2;
matrix m[6][1] =x,y,0,u,v;
derivate(m,f);
  ↪ -2y2+2xz
vector v = [2xz-y2,u6-3];
derivate(m,v);
  ↪ 6u6*gen(2)-2y2*gen(1)+2xz*gen(1)
derivate(m,ideal(2xz-y2,u6-3));
  ↪ _[1]=-2y2+2xz
  ↪ _[2]=6u6

```

D.7.2.3 actionIsProper

Procedure from library `ainvar.lib` (see [Section D.7.2 \[ainvar.lib\], page 1806](#)).

Usage: `actionIsProper(m)`; `m` matrix

Assume: `m` is a `nx1` matrix, where `n` = number of variables of the basering

Return: `int` = 1, if the action defined by `m` is proper, 0 if not

Note: `m` defines a group action which is the exponential of the vector field $m[1,1]*d/dx(1) + \dots + m[1,n]*d/dx(n)$

Example:

```

LIB "ainvar.lib";
ring rf=0,x(1..7),dp;
matrix m[7][1];
m[4,1]=x(1)^3;
m[5,1]=x(2)^3;
m[6,1]=x(3)^3;
m[7,1]=(x(1)*x(2)*x(3))^2;
actionIsProper(m);
  ↪ 0
ring rd=0,x(1..5),dp;
matrix m[5][1];
m[3,1]=x(1);
m[4,1]=x(2);
m[5,1]=1+x(1)*x(4)^2;
actionIsProper(m);
  ↪ 1

```

D.7.2.4 reduction

Procedure from library `ainvar.lib` (see [Section D.7.2 \[ainvar.lib\], page 1806](#)).

Usage: `reduction(p,I[q,n])`; `p` poly, `I` ideal, [`q` monomial, `n` int (optional)]

Return: a polynomial equal to $p-H(f_1,\dots,f_r)$, in case the leading term $LT(p)$ of p is of the form $H(LT(f_1),\dots,LT(f_r))$ for some polynomial H in r variables over the base field, $I=f_1,\dots,f_r$; if q is given, a maximal power a is computed such that q^a divides $p-H(f_1,\dots,f_r)$, and then $(p-H(f_1,\dots,f_r))/q^a$ is returned; return p if no H is found
if $n=1$, a different algorithm is chosen which is sometimes faster (default: $n=0$; q and n can be given (or not) in any order)

Note: this is a kind of SAGBI reduction in the subalgebra $K[f_1, \dots, f_r]$ of the basering

Example:

```
LIB "ainvar.lib";
ring q=0,(x,y,z,u,v,w),dp;
poly p=x2yz-x2v;
ideal dom =x-w,u2w+1,yz-v;
reduction(p,dom);
  ↦ 2xyzw-yzw2-2xvw+vw2
reduction(p,dom,w);
  ↦ 2xyz-yzw-2xv+vw
```

D.7.2.5 completeReduction

Procedure from library `ainvar.lib` (see [Section D.7.2 \[ainvar.lib\], page 1806](#)).

Usage: `completeReduction(p,I[,q,n]);` p poly, I ideal, [q monomial, n int]

Return: a polynomial, the SAGBI reduction of the polynomial p with respect to I via the procedure 'reduction' as long as possible
if n=1, a different algorithm is chosen which is sometimes faster (default: n=0; q and n can be given (or not) in any order)

Note: `help reduction;` shows an explanation of SAGBI reduction

Example:

```
LIB "ainvar.lib";
ring q=0,(x,y,z,u,v,w),dp;
poly p=x2yz-x2v;
ideal dom =x-w,u2w+1,yz-v;
completeReduction(p,dom);
  ↦ 2xyzw-yzw2-2xvw+vw2
completeReduction(p,dom,w);
  ↦ 0
```

D.7.2.6 localInvar

Procedure from library `ainvar.lib` (see [Section D.7.2 \[ainvar.lib\], page 1806](#)).

Usage: `localInvar(m,p,q,h);` m matrix, p,q,h polynomials

Assume: $m(q)$ and h are invariant under the vector field m , i.e. $m(m(q))=m(h)=0$ h must be a ring variable

Return: a polynomial, the invariant polynomial of the vector field

$$m = m[1,1]*d/dx(1) + \dots + m[n,1]*d/dx(n)$$

with respect to p,q,h . It is defined as follows: set $inv = p$ if p is invariant, and else set $inv = m(q)^N * \sum_{i=1..N-1} \{ (-1)^i * (1/i!) * m^i(p) * (q/m(q))^i \}$ where $m^N(p) = 0$, $m^{(N-1)}(p) \neq 0$; the result is inv divided by h as often as possible

Example:

```
LIB "ainvar.lib";
ring q=0,(x,y,z),dp;
matrix m[3][1];
m[2,1]=x;
m[3,1]=y;
```

```

poly in=localInvar(m,z,y,x);
in;
 $\mapsto -1/2y^2+xz$ 

```

D.7.2.7 furtherInvar

Procedure from library `ainvar.lib` (see [Section D.7.2 \[ainvar.lib\], page 1806](#)).

Usage: `furtherInvar(m,id,karl,q);` m matrix, id,karl ideals, q poly, n int

Assume: karl,id,q are invariant under the vector field m,
moreover, q must be a variable

Return: list of two ideals, the first ideal contains further invariants of the vector field
 $m = \sum m[i,1]*d/dx(i)$ with respect to id,p,q,
 i.e. we compute elements in the (invariant) subring generated by id which are divisible
 by q and divide them by q as often as possible. The second ideal contains all invariants
 given before. If n=1, a different algorithm is chosen which is sometimes faster (default:
 n=0)

Example:

```

LIB "ainvar.lib";
ring r=0,(x,y,z,u),dp;
matrix m[4][1];
m[2,1]=x;
m[3,1]=y;
m[4,1]=z;
ideal id=localInvar(m,z,y,x),localInvar(m,u,y,x);
ideal karl=id,x;
list in=furtherInvar(m,id,karl,x);
in;
 $\mapsto$  [1]:
 $\mapsto$   $_{[1]}=y^2z^2-8/3xz^3-2y^3u+6xyzu-3x^2u^2$ 
 $\mapsto$  [2]:
 $\mapsto$   $_{[1]}=-1/2y^2+xz$ 
 $\mapsto$   $_{[2]}=1/3y^3-xyz+x^2u$ 
 $\mapsto$   $_{[3]}=x$ 

```

D.7.2.8 sortier

Procedure from library `ainvar.lib` (see [Section D.7.2 \[ainvar.lib\], page 1806](#)).

Usage: `sortier(id);` id ideal/module

Return: the same ideal/module but with generators ordered by their leading terms, starting
with the smallest

Example:

```

LIB "ainvar.lib";
ring q=0,(x,y,z,u,v,w),dp;
ideal i=w,x,z,y,v;
sortier(i);
 $\mapsto$   $_{[1]}=w$ 
 $\mapsto$   $_{[2]}=v$ 
 $\mapsto$   $_{[3]}=z$ 
 $\mapsto$   $_{[4]}=y$ 
 $\mapsto$   $_{[5]}=x$ 

```

D.7.3 rinvar.lib

Library: rinvar.lib

Purpose: Invariant Rings of Reductive Groups

Author: Thomas Bayer, tbayer@in.tum.de
<http://wwwmayr.informatik.tu-muenchen.de/personen/bayer/> Current Address: Institut fuer Informatik, TU Muenchen

Overview: Implementation based on Derksen's algorithm. Written in the scope of the diploma thesis (advisor: Prof. Gert-Martin Greuel) 'Computations of moduli spaces of semi-quasihomogenous singularities and an implementation in Singular'

Procedures: See also: [Section D.6.18 \[qhmoduli.lib\]](#), page 1746; [Section D.8.10 \[zeroset.lib\]](#), page 1902.

D.7.3.1 HilbertSeries

Procedure from library `rinvar.lib` (see [Section D.7.3 \[rinvar.lib\]](#), page 1811).

Usage: HilbertSeries(I, w); ideal I, intvec w

Purpose: compute the polynomial p of the Hilbert Series, represented by p/q , of the ring $K[t_1, \dots, t_m, y_1, \dots, y_r]/I$ where 'w' are the weights of the variables, computed, e.g., by 'HilbertWeights', 'I' is of the form $I[1] - y_1, \dots, I[r] - y_r$ and is quasihomogenous w.r.t. 'w'

Return: intvec

Note: the leading 0 of the result does not belong to p , but is needed in the Hilbert driven 'std'.

D.7.3.2 HilbertWeights

Procedure from library `rinvar.lib` (see [Section D.7.3 \[rinvar.lib\]](#), page 1811).

Purpose: compute the weights of the "slack" variables needed for the computation of the algebraic relations of the generators of 'I' s.t. the Hilbert driven 'std' can be used.

Return: intvec

Assume: basering = $K[t_1, \dots, t_m, \dots]$, 'I' is quasihomogenous w.r.t. 'w' and contains only polynomials in t_1, \dots, t_m

D.7.3.3 ImageVariety

Procedure from library `rinvar.lib` (see [Section D.7.3 \[rinvar.lib\]](#), page 1811).

Usage: ImageVariety(ideal I, F [, w]); ideal I; F is a list/ideal, intvec w.

Purpose: compute the Zariski closure of the image of the variety of I under the morphism F.

Note: if 'I' and 'F' are quasihomogenous w.r.t. 'w' then the Hilbert-driven 'std' is used.

Return: polynomial ring over the same ground field, containing the ideal 'imageid'. The variables are $Y(1), \dots, Y(k)$ where $k = \text{size}(F) - \text{'imageid'}$ is the ideal of the Zariski closure of $F(X)$ where X is the variety of I.

Example:

```

LIB "rinvar.lib";
ring B = 0,(x,y),dp;
ideal I = x4 - y4;
ideal F = x2, y2, x*y;
def R = ImageVariety(I, F);
↳
↳ // 'ImageVariety' created a new ring.
↳ // To see the ring, type (if the name 'R' was assigned to the return value):
↳      show(R);
↳ // To access the ideal of the image variety, type
↳      setring R; imageid;
↳
setring R;
imageid;
↳ imageid[1]=Y(1)*Y(2)-Y(3)^2
↳ imageid[2]=Y(1)^2-Y(2)^2
↳ imageid[3]=Y(2)^3-Y(1)*Y(3)^2

```

D.7.3.4 ImageGroup

Procedure from library `rinvar.lib` (see [Section D.7.3 \[rinvar.lib\]](#), page 1811).

Usage: `ImageGroup(G, action);` ideal `G`, action;

Purpose: compute the ideal of the image of `G` in $GL(m, K)$ induced by the linear action 'action', where `G` is an algebraic group and 'action' defines an action of `G` on K^m ($\text{size}(\text{action}) = m$).

Return: ring, a polynomial ring over the same ground field as the basering, containing the ideals 'groupid' and 'actionid'.
 - 'groupid' is the ideal of the image of `G` (order \leq order of `G`) - 'actionid' defines the linear action of 'groupid' on K^m .

Note: 'action' and 'actionid' have the same orbits
 all variables which give only rise to 0's in the $m \times m$ matrices of `G` have been omitted.

Assume: basering $K[s(1..r), t(1..m)]$ has $r + m$ variables, `G` is the ideal of an algebraic group and `F` is an action of `G` on K^m . `G` contains only the variables $s(1) \dots s(r)$. The action 'action' is given by polynomials f_1, \dots, f_m in basering, s.t. on the ring level we have $K[t_1, \dots, t_m] \rightarrow K[s_1, \dots, s_r, t_1, \dots, t_m]/G$
 $t_i \rightarrow f_i(s_1, \dots, s_r, t_1, \dots, t_m)$

Example:

```

LIB "rinvar.lib";
ring B = 0,(s(1..2), t(1..2)),dp;
ideal G = s(1)^3-1, s(2)^10-1;
ideal action = s(1)*s(2)^8*t(1), s(1)*s(2)^7*t(2);
def R = ImageGroup(G, action);
↳
↳ // 'ImageGroup' created a new ring.
↳ // To see the ring, type (if the name 'R' was assigned to the return value):
↳      show(R);
↳ // To access the ideal of the image of the input group and to access the \

```

```

new
⇒ // action of the group, type
⇒      setring R;  groupid; actionid;
⇒
setring R;
groupid;
⇒ groupid[1]=-s(1)+s(2)^4
⇒ groupid[2]=s(1)^8-s(2)^2
⇒ groupid[3]=s(1)^7*s(2)^2-1
actionid;
⇒ actionid[1]=s(1)*t(1)
⇒ actionid[2]=s(2)*t(2)

```

D.7.3.5 InvariantRing

Procedure from library `rinvar.lib` (see [Section D.7.3 \[rinvar.lib\]](#), page 1811).

Usage: InvariantRing(G, Gact [, opt]); ideal G, Gact; int opt

Purpose: compute generators of the invariant ring of G w.r.t. the action 'Gact'

Assume: G is a finite group and 'Gact' is a linear action.

Return: ring R; this ring comes with the ideals 'invars' and 'groupid' and with the poly 'newA':
 - 'invars' contains the algebra generators of the invariant ring - 'groupid' is the ideal of
 G in the new ring
 - 'newA' is the new representation of the primitive root of the minimal polynomial of
 the ring which was active when calling the procedure (if the minpoly did not change,
 'newA' is set to 'a').

Note: the minimal polynomial of the output ring depends on some random choices

Example:

```

LIB "rinvar.lib";
ring B = 0, (s(1..2), t(1..2)), dp;
ideal G = -s(1)+s(2)^3, s(1)^4-1;
ideal action = s(1)*t(1), s(2)*t(2);
def R = InvariantRing(std(G), action);
⇒
⇒ // 'InvariantRing' created a new ring.
⇒ // To see the ring, type (if the name 'R' was assigned to the return valu\
e):
⇒      show(R);
⇒ // To access the generators of the invariant ring type
⇒      setring R; invars;
⇒ // Note that the input group G is stored in R as the ideal 'groupid'; to
⇒ // see it, type
⇒      groupid;
⇒ // Note that 'InvariantRing' might change the minimal polynomial
⇒ // The representation of the algebraic number is given by 'newA'
⇒
setring R;
invars;
⇒ invars[1]=t(1)^4
⇒ invars[2]=t(1)^3*t(2)^3
⇒ invars[3]=t(1)^2*t(2)^6

```

```

↳ invars[4]=t(1)*t(2)^9
↳ invars[5]=t(2)^12

```

D.7.3.6 InvariantQ

Procedure from library `rinvar.lib` (see [Section D.7.3 \[rinvar.lib\], page 1811](#)).

Usage: InvariantQ(f, G, action); poly f; ideal G, action

Purpose: check whether the polynomial f is invariant w.r.t. G, where G acts via 'action' on K^m .

Assume: basering = $K[s_1, \dots, s_m, t_1, \dots, t_m]$ where $K = \mathbb{Q}$ or $K = \mathbb{Q}(a)$ and minpoly $\neq 0$, f contains only t_1, \dots, t_m , G is the ideal of an algebraic group and a standardbasis.

Return: int;
0 if f is not invariant,
1 if f is invariant

Note: G need not be finite

D.7.3.7 LinearizeAction

Procedure from library `rinvar.lib` (see [Section D.7.3 \[rinvar.lib\], page 1811](#)).

Usage: LinearizeAction(G, action, r); ideal G, action; int r

Purpose: linearize the group action 'action' and find an equivariant embedding of K^m where $m = \text{size}(\text{action})$.

Assume: G contains only variables `var(1..r)` ($r = \text{nrs}$)
basing = $K[s(1..r), t(1..m)]$, $K = \mathbb{Q}$ or $K = \mathbb{Q}(a)$ and minpoly $\neq 0$.

Return: polynomial ring containing the ideals 'actionid', 'embedid', 'groupid' - 'actionid' is the ideal defining the linearized action of G - 'embedid' is a parameterization of an equivariant embedding (closed) - 'groupid' is the ideal of G in the new ring

Note: set `printlevel > 0` to see a trace

Example:

```

LIB "rinvar.lib";
ring B = 0, (s(1..5), t(1..3)), dp;
ideal G = s(3)-s(4), s(2)-s(5), s(4)*s(5), s(1)^2*s(4)+s(1)^2*s(5)-1, s(1)^2*s(5)^2-1;
ideal action = -s(4)*t(1)+s(5)*t(1), -s(4)^2*t(2)+2*s(4)^2*t(3)^2+s(5)^2*t(2), s(4)*t(3)-s(5)*t(3);
LinearActionQ(action, 5);
↳ 0
def R = LinearizeAction(G, action, 5);
↳
↳ // 'LinearizeAction' created a new ring.
↳ // To see the ring, type (if the name 'R' was assigned to the return value):
↳ show(R);
↳ // To access the new action and the equivariant embedding, type
↳ setring R; actionid; embedid; groupid
↳
setring R;
R;
↳ // coefficients: QQ
↳ // number of vars : 9

```

```

⇒ //          block   1 : ordering dp
⇒ //          : names   s(1) s(2) s(3) s(4) s(5) t(1) t(2) t(3) t(\
  4)
⇒ //          block   2 : ordering C
actionid;
⇒ actionid[1]=-s(4)*t(1)+s(5)*t(1)
⇒ actionid[2]=-s(4)^2*t(2)+s(5)^2*t(2)+2*s(4)^2*t(4)
⇒ actionid[3]=s(4)*t(3)+s(5)*t(3)
⇒ actionid[4]=s(4)^2*t(4)+s(5)^2*t(4)
embedid;
⇒ embedid[1]=t(1)
⇒ embedid[2]=t(2)
⇒ embedid[3]=t(3)
⇒ embedid[4]=t(3)^2
groupid;
⇒ groupid[1]=s(3)-s(4)
⇒ groupid[2]=s(2)-s(5)
⇒ groupid[3]=s(4)*s(5)
⇒ groupid[4]=s(1)^2*s(4)+s(1)^2*s(5)-1
⇒ groupid[5]=s(1)^2*s(5)^2-s(5)
⇒ groupid[6]=s(4)^4-s(5)^4+s(1)^2
⇒ groupid[7]=s(1)^4+s(4)^3-s(5)^3
⇒ groupid[8]=s(5)^5-s(1)^2*s(5)
LinearActionQ(actionid, 5);
⇒ 1

```

D.7.3.8 LinearActionQ

Procedure from library `rinvar.lib` (see [Section D.7.3 \[rinvar.lib\]](#), page 1811).

Usage: LinearActionQ(action,nrs); ideal action, int nrs

Purpose: check whether the action defined by 'action' is linear w.r.t. the variables `var(nrs + 1...nvars(basering))`.

Return: 0 action not linear
 1 action is linear

Example:

```

LIB "rinvar.lib";
ring R = 0,(s(1..5), t(1..3)),dp;
ideal G = s(3)-s(4), s(2)-s(5), s(4)*s(5), s(1)^2*s(4)+s(1)^2*s(5)-1,
s(1)^2*s(5)^2-s(5), s(4)^4-s(5)^4+s(1)^2, s(1)^4+s(4)^3-s(5)^3,
s(5)^5-s(1)^2*s(5);
ideal Gaction = -s(4)*t(1)+s(5)*t(1),
-s(4)^2*t(2)+2*s(4)^2*t(3)^2+s(5)^2*t(2),
s(4)*t(3)+s(5)*t(3);
LinearActionQ(Gaction, 5);
⇒ 0
LinearActionQ(Gaction, 8);
⇒ 1

```

D.7.3.9 LinearCombinationQ

Procedure from library `rinvar.lib` (see [Section D.7.3 \[rinvar.lib\]](#), page 1811).

Usage: LinearCombination(I, f); ideal I, poly f
Purpose: test whether f can be written as a linear combination of the generators of I.
Return: 0 f is not a linear combination
 1 f is a linear combination

D.7.3.10 MinimalDecomposition

Procedure from library `rinvar.lib` (see [Section D.7.3 \[rinvar.lib\], page 1811](#)).

Usage: MinimalDecomposition(f,a,b); poly f; int a, b.
Purpose: decompose f as a sum $M[1,1]*M[2,1] + \dots + M[1,r]*M[2,r]$ where $M[1,i]$ contains only $s(1..a)$, $M[2,i]$ contains only $t(1..b)$ s.t. r is minimal
Assume: f polynomial in $K[s(1..a), t(1..b)]$, $K = \mathbb{Q}$ or $K = \mathbb{Q}(a)$ and $\text{minpoly} \neq 0$
Return: $2 \times r$ matrix M s.t. $f = M[1,1]*M[2,1] + \dots + M[1,r]*M[2,r]$

Example:

```
LIB "rinvar.lib";
ring R = 0, (s(1..2), t(1..2)), dp;
poly h = s(1)*(t(1) + t(1)^2) + (t(2) + t(2)^2)*(s(1)^2 + s(2));
matrix M = MinimalDecomposition(h, 2, 2);
M;
  ↳ M[1,1]=s(1)^2+s(2)
  ↳ M[1,2]=s(1)
  ↳ M[2,1]=t(2)^2+t(2)
  ↳ M[2,2]=t(1)^2+t(1)
M[1,1]*M[2,1] + M[1,2]*M[2,2] - h;
  ↳ 0
```

D.7.3.11 NullCone

Procedure from library `rinvar.lib` (see [Section D.7.3 \[rinvar.lib\], page 1811](#)).

Usage: NullCone(G, action); ideal G, action
Purpose: compute the ideal of the nullcone of the linear action of G on K^n , given by 'action', by means of Deksen's algorithm
Assume: $\text{basering} = K[s(1..r), t(1..n)]$, $K = \mathbb{Q}$ or $K = \mathbb{Q}(a)$ and $\text{minpoly} \neq 0$, G is an ideal of a reductive algebraic group in $K[s(1..r)]$, 'action' is a linear group action of G on K^n ($n = \text{ncols}(\text{action})$)
Return: ideal of the nullcone of G.
Note: the generators of the nullcone are homogeneous, but in general not invariant

Example:

```
LIB "rinvar.lib";
ring R = 0, (s(1..2), x, y), dp;
ideal G = -s(1)+s(2)^3, s(1)^4-1;
ideal action = s(1)*x, s(2)*y;
ideal inv = NullCone(G, action);
inv;
  ↳ inv[1]=x^4
  ↳ inv[2]=x^3*y^3
```

```

 $\mapsto$  inv[3]=x^2*y^6
 $\mapsto$  inv[4]=x*y^9
 $\mapsto$  inv[5]=y^12

```

D.7.3.12 ReynoldsImage

Procedure from library `rinvar.lib` (see [Section D.7.3 \[rinvar.lib\]](#), page 1811).

Usage: `ReynoldsImage(RO, f);` list RO, poly f

Purpose: compute the Reynolds image of the polynomial f, where RO represents the Reynolds operator

Return: poly

D.7.3.13 ReynoldsOperator

Procedure from library `rinvar.lib` (see [Section D.7.3 \[rinvar.lib\]](#), page 1811).

Usage: `ReynoldsOperator(G, action [, opt]);` ideal G, action; int opt

Purpose: compute the Reynolds operator of the group G which acts via 'action'

Return: polynomial ring R over a simple extension of the ground field of the basering (the extension might be trivial), containing a list 'ROelements', the ideals 'id', 'actionid' and the polynomial 'newA'. $R = K(a)[s(1..r), t(1..n)]$.
 - 'ROelements' is a list of ideals, each ideal represents a substitution map $F : R \rightarrow R$ according to the zero-set of G - 'id' is the ideal of G in the new ring
 - 'newA' is the new representation of a' in terms of a. If the basering does not contain a parameter then 'newA' = 'a'.

Assume: $\text{basing} = K[s(1..r), t(1..n)]$, $K = \mathbb{Q}$ or $K = \mathbb{Q}(a')$ and $\text{minpoly} \neq 0$, G is the ideal of a finite group in $K[s(1..r)]$, 'action' is a linear group action of G

D.7.3.14 SimplifyIdeal

Procedure from library `rinvar.lib` (see [Section D.7.3 \[rinvar.lib\]](#), page 1811).

Purpose: simplify ideal I to the ideal I', do not change the names of the first m variables, new ideal I' might contain less variables. I' contains variables `var(1..m)`

Return: list
 -[1] ideal I'
 -[2] ideal representing a map phi to a ring with probably less vars. s.th. $\text{phi}(I) = I'$
 -[3] list of variables
 -[4] list from 'elimpart'

D.7.4 invar.lib

Library: `invar.lib`

Purpose: Procedures to compute invariant rings of $SL(n)$ and torus groups

Author: Harm Derksen, `hderksen@math.unibas.ch`

Procedures:

D.7.4.1 SL

Procedure from library `invar.lib` (see [Section D.7.4 \[invar.lib\], page 1817](#)).

Usage: `SL(<int>)`

Returns: `SL(n)` sets the current group to `SL_n`. The following global variables will be set:
 group of type `<ring>`
 groupideal of type `<ideal>`
 SLrep of type `<matrix>`
 reynolds of type `<proc>`
 The quotient of `'group'` and `'groupideal'` is the coordinate ring of `SL_n`. The matrix `'SLrep'` will be set to the standard representation of `SL_n`. The basering will be set to `'group'`.

Example:

```
LIB "invar.lib";
SL(3);
Invar::group;
⇨ // coefficients: QQ
⇨ // number of vars : 9
⇨ //          block 1 : ordering dp
⇨ //          : names  g(1) g(2) g(3) g(4) g(5) g(6) g(7) g(8) g(\
9)
⇨ //          block 2 : ordering C
groupideal;
⇨ groupideal[1]=g(3)*g(5)*g(7)-g(2)*g(6)*g(7)-g(3)*g(4)*g(8)+g(1)*g(6)*g(8)\
+g(2)*g(4)*g(9)-g(1)*g(5)*g(9)+1
print(SLrep);
⇨ g(1),g(2),g(3),
⇨ g(4),g(5),g(6),
⇨ g(7),g(8),g(9)
```

D.7.4.2 torus

Procedure from library `invar.lib` (see [Section D.7.4 \[invar.lib\], page 1817](#)).

Usage: `torus(<int>)`

Returns: `torus(n)` sets the current group to an `n`-dimensional torus. The following global variables will be changed:
 group of type `<ring>`
 groupideal of type `<ideal>`
 reynolds of type `<proc>`
 The quotient of `'group'` and `'groupideal'` is the coordinate ring of an `n`-dimensional torus. The basering will be set to `'group'`.

Example:

```
LIB "invar.lib";
torus(3);
Invar::group;
⇨ // coefficients: QQ
⇨ // number of vars : 4
⇨ //          block 1 : ordering dp
⇨ //          : names  g(1) g(2) g(3) g(4)
```

```

⇒ //          block    2 : ordering C
groupideal;
⇒ groupideal[1]=g(1)*g(2)*g(3)*g(4)-1

```

D.7.4.3 torusrep

Procedure from library `invar.lib` (see [Section D.7.4 \[invar.lib\]](#), page 1817).

Usage: `torusrep(<list>)`, `<list>` must be a list of integer vectors of length `n`, where `n` is the dimension of the current torusgroup.

Returns: `torusrep(m)` gives a matrix with entries in 'group'. This matrix represents the action of the torus with weights
`m[1],m[2],...,m[size(m)]`

Example:

```

LIB "invar.lib";
torus(1);           // Take the 1-dimensional torus, the multiplicative group
list weights=-2,-3,7; // 3-dimensional action with weights -2,-3,7
matrix m=torusrep(weights); // compute the matrix of the representation
invar(m);           // compute the invariant ring
⇒
⇒ Ideal B:
⇒ x(1)^2*x(2)*x(3)-y(1)^2*y(2)*y(3),
⇒ x(2)^2*y(1)^3-x(1)^3*y(2)^2,
⇒ x(2)^3*x(3)*y(1)-x(1)*y(2)^3*y(3),
⇒ x(1)^5*x(3)*y(2)-x(2)*y(1)^5*y(3),
⇒ x(1)*x(2)^4*x(3)^2-y(1)*y(2)^4*y(3)^2,
⇒ x(1)^7*x(3)^2-y(1)^7*y(3)^2,
⇒ x(2)^7*x(3)^3-y(2)^7*y(3)^3
⇒
⇒ Zero Fiber Ideal:
⇒ x(1)^2*x(2)*x(3),
⇒ x(1)*x(2)^4*x(3)^2,
⇒ x(1)^7*x(3)^2,
⇒ x(2)^7*x(3)^3
⇒
⇒ Generating Invariants:
⇒ x(1)^2*x(2)*x(3),
⇒ x(1)*x(2)^4*x(3)^2,
⇒ x(1)^7*x(3)^2,
⇒ x(2)^7*x(3)^3

```

D.7.4.4 finiterep

Procedure from library `invar.lib` (see [Section D.7.4 \[invar.lib\]](#), page 1817).

Usage: `finiterep(<list>)`, `<list>` must be a list of matrices

Returns: `finiterep(m)` gives a matrix with coefficients in the ring 'group' which represents the action of the finite group where the elements of the finite group act as
`m[1],m[2],...,m[size(m)]`.

Example:

```

LIB "invar.lib";
finite(6);                                // The symmetric group S_3
matrix id=unitmat(3);                     // identity matrix
matrix m3[3][3]=0,1,0,0,0,1,1,0,0;        // corresponds with (1 2 3)
matrix m2[3][3]=0,1,0,1,0,0,0,0,1;        // corresponds with (1 2)
list a=id,m3,m3*m3,m2,m2*m3,m2*m3*m3;    // all elements of S_3
matrix rep=finiterep(a);                  // compute matrix of standard repr.
invar(rep);                               // compute the invariant ring

D.7.4.5 sympower

Procedure from library `invar.lib` (see [Section D.7.4 \[invar.lib\]](#), page 1817).

Usage: `sympower(<matrix>,<int>)`

Returns: If `m` is a matrix with coefficients in the ring 'group', representing the action on some vector space `V`, then `sympower(m,n)` gives the matrix of the representation of the group on the `n`-th symmetric power of `V`.

Example:

```

LIB "invar.lib";
SL(2);
print(SLrep);
↳ g(1),g(2),
↳ g(3),g(4)
print(sympower(SLrep,3));
↳ g(1)^3,      3*g(1)^2*g(2),      3*g(1)*g(2)^2,      g(2)^3,

```

$$\begin{aligned} \mapsto & g(1)^2g(3), 3g(1)^2g(4)-2g(1), 3g(1)g(2)g(4)-g(2), g(2)^2g(4), \\ \mapsto & g(1)g(3)^2, 3g(1)g(3)g(4)-g(3), 3g(1)g(4)^2-2g(4), g(2)g(4)^2, \\ \mapsto & g(3)^3, 3g(3)^2g(4), 3g(3)g(4)^2, g(4)^3 \end{aligned}$$

D.7.4.6 invar

Procedure from library `invar.lib` (see [Section D.7.4 \[invar.lib\]](#), page 1817).

Usage: `invar(<matrix>)`

Returns: If m is a $n \times n$ matrix with coefficients in the ring 'group', representing the action on some vector space V , then `invar(m)` gives polynomials in $x(1), x(2), \dots, x(n)$ who generate the invariant ring. The following global variables will be set:
 polyring of type `<ring>` polynomial ring in $x(1), \dots, x(n)$ invring of type `<ideal>` entries generate the inv. ring representation of type `<matrix>`
 The base ring will be set to 'polyring' which is a global variable representing the polynomial ring on which the group acts. The variable 'representation' will be set to the input m .

Example:

```
LIB "invar.lib";
SL(2);                                // Take the group SL_2
matrix m=dsum(SLrep,SLrep,SLrep,SLrep);
// 4 copies of the standard representation
invar(m);                             // empirical evidence for FFT
\mapsto
\mapsto Ideal B:

    // the Omega process.

```

D.7.4.7 SLreynolds

Procedure from library `invar.lib` (see [Section D.7.4 \[invar.lib\]](#), page 1817).

Usage: SLreynolds(f) poly f
Returns: the reynolds operator applied to f
Note: if the group is SL_n the omega-process is used

D.7.4.8 torusreynolds

Procedure from library `invar.lib` (see [Section D.7.4 \[invar.lib\]](#), page 1817).

D.7.5 stratify_lib

Library: stratify.lib
Purpose: Algorithmic Stratification for Unipotent Group-Actions
Author: Anne Fruehbis-Krueger, anne@mathematik.uni-kl.de
Procedures:

D.7.5.1 prepMat

Procedure from library `stratify.lib` (see [Section D.7.5 \[stratify.lib\]](#), page 1822).

Usage: prepMat(M,wr,ws,step);
 where M is a matrix, wr is an intvec of size ncols(M), ws an intvec of size nrows(M) and step is an integer
Return: 2 lists of submatrices corresponding to the filtrations specified by wr and ws:
 the first list corresponds to the list for the filtration of AdA , i.e. the ranks of these matrices will be the r_i , the second one to the list for the filtration of L , i.e. the ranks of these matrices will be the s_i
Note: * the entries of the matrix M are $M_{ij}=\delta_i(x_j)$,
 * wr is used to determine what subset of the set of all dx_i is generating $AdF^1(A)$:
 if $(k-1)*step \leq wr[i] < k*step$, then dx_i is in the set of generators of $AdF^1(A)$ for all $l \geq k$ and the i-th column of M appears in each submatrix starting from the k-th

* ws is used to determine what subset of the set of all $\delta_{i,j}$ is generating $Z_1(L)$:
 if $(k-1)*step \leq ws[i] < k*step$, then $\delta_{i,j}$ is in the set of generators of $Z_1(A)$ for $1 \leq j \leq k$ and the i -th row of M appears in each submatrix up to the $(k-1)$ th
 * the entries of wr and ws as well as $step$ should be positive integers

Example:

```
LIB "stratify.lib";
ring r=0,(t(1..3)),dp;
matrix M[2][3]=0,t(1),3*t(2),0,0,t(1);
print(M);
  ↪ 0,t(1),3*t(2),
  ↪ 0,0,    t(1)
intvec wr=1,3,5;
intvec ws=2,4;
int step=2;
prepMat(M,wr,ws,step);
  ↪ [1]:
  ↪   [1]:
  ↪     _[1,1]=0
  ↪     _[2,1]=0
  ↪   [2]:
  ↪     _[1,1]=0
  ↪     _[1,2]=t(1)
  ↪     _[2,1]=0
  ↪     _[2,2]=0
  ↪   [3]:
  ↪     _[1,1]=0
  ↪     _[1,2]=t(1)
  ↪     _[1,3]=3*t(2)
  ↪     _[2,1]=0
  ↪     _[2,2]=0
  ↪     _[2,3]=t(1)
  ↪ [2]:
  ↪   [1]:
  ↪     _[1,1]=0
  ↪     _[1,2]=t(1)
  ↪     _[1,3]=3*t(2)
  ↪     _[2,1]=0
  ↪     _[2,2]=0
  ↪     _[2,3]=t(1)
  ↪   [2]:
  ↪     _[1,1]=0
  ↪     _[1,2]=0
  ↪     _[1,3]=t(1)
```

D.7.5.2 stratify

Procedure from library `stratify.lib` (see [Section D.7.5 \[stratify.lib\]](#), page 1822).

Usage: `stratify(M,wr,ws,step);`
 where M is a matrix, wr is an intvec of size $\text{ncols}(M)$, ws an intvec of size $\text{nrows}(M)$
 and $step$ is an integer

Return: list of lists, each entry of the big list corresponds to one locally closed set and has the following entries:

- 1) intvec giving the corresponding rs-vector
- 2) ideal determining the closed set
- 3) list d of polynomials determining the open set $D(d[1])$ empty list if there is more than one open set
- 4-n) lists of polynomials determining open sets which all lead to the same rs-vector

Note:

- * ring ordering should be global, i.e. the ring should be a polynomial ring
- * the entries of the matrix M are $M_{ij} = \delta_{ij}(x_j)$,
- * wr is used to determine what subset of the set of all dx_i is generating $\text{AdF}^l(A)$:
if $(k-1)*\text{step} < \text{wr}[i] \leq k*\text{step}$, then dx_i is in the set of generators of $\text{AdF}^l(A)$ for all $l \geq k$
- * ws is used to determine what subset of the set of all δ_{ij} is generating $Z_l(L)$:
if $(k-1)*\text{step} \leq \text{ws}[i] < k*\text{step}$, then δ_{ij} is in the set of generators of $Z_l(A)$ for $l < k$
- * the entries of wr and ws as well as step should be positive integers
- * the filtrations have to be known, no sanity checks concerning the filtrations are performed !!!

Example:

```
LIB "stratify.lib";
ring r=0,(t(1..3)),dp;
matrix M[2][3]=0,t(1),3*t(2),0,0,t(1);
intvec wr=1,3,5;
intvec ws=2,4;
int step=2;
stratify(M,wr,ws,step);

D.8 Symbolic-numerical solving

D.8.1 ffsolve_lib

Library: ffsolve.lib

Purpose: multivariate equation solving over finite fields

Author: Gergo Gyula Borus, borisz@borisz.net

Procedures:

D.8.1.1 ffsolve

Procedure from library `ffsolve.lib` (see [Section D.8.1 \[ffsolve.lib\], page 1825](#)).

Usage: ffsolve(I[, L]); I ideal, L list of strings

Return: list L, the common roots of I as ideal

Assume: basering is a finite field of type (p^n, a)

Example:

```

LIB "ffsolve.lib";
ring R = (2,a),x(1..3),lp;
minpoly=a2+a+1;
ideal I;
I[1]=x(1)^2*x(2)+(a)*x(1)*x(2)^2+(a+1);
I[2]=x(1)^2*x(2)*x(3)^2+(a)*x(1);
I[3]=(a+1)*x(1)*x(3)+(a+1)*x(1);
ffsolve(I);
↦ [1]:
↦   _[1]=x(3)+1
↦   _[2]=x(2)+(a)
↦   _[3]=x(1)+1
↦ [2]:
↦   _[1]=x(3)+1
↦   _[2]=x(2)+(a+1)
↦   _[3]=x(1)+(a+1)

```

D.8.1.2 PEsolve

Procedure from library `ffsolve.lib` (see [Section D.8.1 \[ffsolve.lib\], page 1825](#)).

Usage: PEsolve(I[, i]); I ideal, i optional integer
 solve I (system of multivariate equations) over a
 finite field using an equivalence property when i is
 not given or set to 2, otherwise if i is set to 0
 then check whether common roots exists

Return: list if optional parameter is not given or set to 2,
 integer if optional is set to 0

Assume: basering is a finite field of type (p^n, a)

Note: When the optional parameter is set to 0, speoff only checks if I has common roots, then return 1, otherwise return 0.

Example:

```
LIB "ffsolve.lib";
ring R = (2,a),x(1..3),lp;
minpoly=a2+a+1;
ideal I;
I[1]=x(1)^2*x(2)+(a)*x(1)*x(2)^2+(a+1);
I[2]=x(1)^2*x(2)*x(3)^2+(a)*x(1);
I[3]=(a+1)*x(1)*x(3)+(a+1)*x(1);
PEsolve(I);
⇒ // ** redefining I ( ideal I = defaultIdeal();) ffsolve.lib::productOfEq\
s:1001

⇒ // ** redefining new ( list new = increment(start,i);) ffsolve.lib::\
melyseg:969
⇒ // ** redefining l (int l=1;) ffsolve.lib::melyseg:970
⇒ [1]:
⇒ _[1]=x(3)+1
⇒ _[2]=x(2)+(a)
```

```

↳      _[3]=x(1)+1
↳ [2] :
↳      _[1]=x(3)+1
↳      _[2]=x(2)+(a+1)
↳      _[3]=x(1)+(a+1)

```

D.8.1.3 simplesolver

Procedure from library `ffsolve.lib` (see [Section D.8.1 \[ffsolve.lib\]](#), page 1825).

Usage: `simplesolver(I)`; I ideal
 solve I (system of multivariate equations) over a
 finite field by exhausting search

Return: list L, the common roots of I as ideal

Assume: basering is a finite field of type (p^n, a)

Example:

```

LIB "ffsolve.lib";
ring R = (2,a),x(1..3),lp;
minpoly=a2+a+1;
ideal I;
I[1]=x(1)^2*x(2)+(a)*x(1)*x(2)^2+(a+1);
I[2]=x(1)^2*x(2)*x(3)^2+(a)*x(1);
I[3]=(a+1)*x(1)*x(3)+(a+1)*x(1);
simplesolver(I);
↳ [1] :
↳      _[1]=x(3)+1
↳      _[2]=x(2)+(a)
↳      _[3]=x(1)+1
↳ [2] :
↳      _[1]=x(3)+1
↳      _[2]=x(2)+(a+1)
↳      _[3]=x(1)+(a+1)

```

D.8.1.4 GBsolve

Procedure from library `ffsolve.lib` (see [Section D.8.1 \[ffsolve.lib\]](#), page 1825).

Usage: `GBsolve(I)`; I ideal
 solve I (system of multivariate equations) over an
 extension of \mathbb{Z}/p by Groebner basis methods

Return: list L, the common roots of I as ideal

Assume: basering is a finite field of type (p^n, a)

Example:

```

LIB "ffsolve.lib";
ring R = (2,a),x(1..3),lp;
minpoly=a2+a+1;
ideal I;
I[1]=x(1)^2*x(2)+(a)*x(1)*x(2)^2+(a+1);
I[2]=x(1)^2*x(2)*x(3)^2+(a)*x(1);
I[3]=(a+1)*x(1)*x(3)+(a+1)*x(1);

```

```

GBsolve(I);
↳ [1]:
↳   _[1]=x(3)+1
↳   _[2]=x(2)+(a)
↳   _[3]=x(1)+1
↳ [2]:
↳   _[1]=x(3)+1
↳   _[2]=x(2)+(a+1)
↳   _[3]=x(1)+(a+1)

```

D.8.1.5 XLsolve

Procedure from library `ffsolve.lib` (see [Section D.8.1 \[ffsolve.lib\]](#), page 1825).

Usage: `XLsolve(I[, d]);` I ideal, d optional integer
 solve I (system of multivariate polynomials) with a
 variant of the linearization technique, multiplying
 the polynomials with monomials of degree at most d
 (default is 2)

Return: list L of the common roots of I as ideals

Assume: basering is a finite field of type (p^n, a)

Example:

```

LIB "ffsolve.lib";
ring R = (2,a),x(1..3),lp;
minpoly=a2+a+1;
ideal I;
I[1]=(a)*x(1)^2+x(2)^2+(a+1);
I[2]=(a)*x(1)^2+(a)*x(1)*x(3)+(a)*x(2)^2+1;
I[3]=(a)*x(1)*x(3)+1;
I[4]=x(1)^2+x(1)*x(3)+(a);
XLsolve(I, 3);
↳ [1]:
↳   _[1]=x(3)+(a+1)
↳   _[2]=x(2)+1
↳   _[3]=x(1)+1

```

D.8.1.6 ZZsolve

Procedure from library `ffsolve.lib` (see [Section D.8.1 \[ffsolve.lib\]](#), page 1825).

Usage: `ZZsolve(I);` I ideal
 solve I (system of multivariate equations) over a
 finite field by mapping the polynomials to a single
 univariate polynomial over extension of the basering

Return: list, the common roots of I as ideal

Assume: basering is a finite field of type (p^n, a)

Example:

```

LIB "ffsolve.lib";
ring R = (2,a),x(1..3),lp;
minpoly=a2+a+1;

```

```

ideal I;
I[1]=x(1)^2*x(2)+(a)*x(1)*x(2)^2+(a+1);
I[2]=x(1)^2*x(2)*x(3)^2+(a)*x(1);
I[3]=(a+1)*x(1)*x(3)+(a+1)*x(1);
ZZsolve(I);
⇒ [1]:
⇒   _[1]=x(3)+1
⇒   _[2]=x(2)+(a)
⇒   _[3]=x(1)+1
⇒ [2]:
⇒   _[1]=x(3)+1
⇒   _[2]=x(2)+(a+1)
⇒   _[3]=x(1)+(a+1)

```

D.8.2 interval_lib

Library: interval.lib

Purpose: implements interval arithmetic on polynomials

Authors: Dominik Bendle
Clara Petroll

Overloads:

```

// intervals
[ intervalGet indexing
= intervalAssign assigning
== intervalEqual equality
print intervalPrint pretty print
+ intervalAdd addition
- intervalNegate negation (unary)
- intervalSubtract subtraction
* intervalMultiply multiplication
/ intervalDivide division
^ intervalPotentiate potentiation

// boxes
= boxSet assigning
[ boxGet indexing
== boxEqual equality
print boxPrint printing
- boxSubtract subtraction
intersect boxIntersect intersection

// intervalmatrices
[ ivmatGet indexing
print ivmatPrint printing
nrows ivmatNrows number of rows
ncols ivmatNcols number of columns
det determinant determinant
* ivmatMultiply matrix multiplication

```

Procedures: See also: [Section D.8.8 \[rootisolation_lib\]](#), page 1894.

D.8.2.1 length2

Procedure from library `interval.lib` (see [Section D.8.2 \[interval.lib\], page 1829](#)).

Usage: `length2(I)`, `I` interval

Return: `length/size` in measure sense

Example:

```
LIB "interval.lib";
ring R = 0,x,lp;
interval I = bounds2(0, 1);      I;
⇒ [0, 1]
⇒
length2(I);
⇒ 1
I = bounds2(-1/2, 3/7);          I;
⇒ [-1/2, 3/7]
⇒
length2(I);
⇒ 13/14
```

D.8.2.2 bounds2

Procedure from library `interval.lib` (see [Section D.8.2 \[interval.lib\], page 1829](#)).

Usage: `bounds2(a, b)`, `a`, `b` number

Return: interval `[a, b]`.

D.8.2.3 intervalmatrixInit

Procedure from library `interval.lib` (see [Section D.8.2 \[interval.lib\], page 1829](#)).

Usage: `intervalmatrixInit(m, n)` `m`, `n` int

Return: `mxn` matrix of `[0,0]`-intervals

Example:

```
LIB "interval.lib";
ring R = 0,x(1..5),lp;
ivmat A = intervalmatrixInit(4, 5); A;
⇒ [0, 0],[0, 0],[0, 0],[0, 0],[0, 0]
⇒ [0, 0],[0, 0],[0, 0],[0, 0],[0, 0]
⇒ [0, 0],[0, 0],[0, 0],[0, 0],[0, 0]
⇒ [0, 0],[0, 0],[0, 0],[0, 0],[0, 0]
⇒
```

D.8.2.4 unitMatrix2

Procedure from library `interval.lib` (see [Section D.8.2 \[interval.lib\], page 1829](#)).

Usage: `unitMatrix2(n)`

Return: `nxn` unit matrix

Example:

```

LIB "interval.lib";
ring R = 0,x,lp;
ivmat E = unitMatrix2(4); E;
↳ [1, 1],[0, 0],[0, 0],[0, 0]
↳ [0, 0],[1, 1],[0, 0],[0, 0]
↳ [0, 0],[0, 0],[1, 1],[0, 0]
↳ [0, 0],[0, 0],[0, 0],[1, 1]
↳

```

D.8.2.5 applyMatrix

Procedure from library `interval.lib` (see [Section D.8.2 \[interval.lib\]](#), page 1829).

Usage: `A * b`, `A ivmat`, `b box`

Return: `A*b`

Example:

```

LIB "interval.lib";
ring R = 0,(x,y,z),lp;
ideal I = xyz3+z2y2+x,x4+y3+2z+3,xyz+1/2;
interval J = bounds2(1/2, 3/2);
box B = list(J,J,J);
ivmat A = evalJacobianAtBox(I, B); A;
↳ [17/16, 97/16],[5/16, 189/16],[7/16, 351/16]
↳ [1/2, 27/2],[3/4, 27/4],[2, 2]
↳ [1/4, 9/4],[1/4, 9/4],[1/4, 9/4]
↳
A*B;
↳ [29/32, 1911/32],[13/8, 267/8],[3/8, 81/8]
↳
unitMatrix2(3) * B;
↳ [1/2, 3/2],[1/2, 3/2],[1/2, 3/2]
↳
diagMatrix(3, bounds2(0, 1)) * B;
↳ [0, 3/2],[0, 3/2],[0, 3/2]
↳

```

D.8.2.6 ivmatGaussian2

Procedure from library `interval.lib` (see [Section D.8.2 \[interval.lib\]](#), page 1829).

Usage: `ivmatGaussian2(A)` `A ivmat`

Return: 0 if `A` not invertible, 1, `Ainv` if `A` invertible

Example:

```

LIB "interval.lib";
ring R = 0,(x,y),lp;
ideal I = 2x2-xy+2y2-2,2x2-3xy+3y2-2;
box B = list(bounds2(7/8, 9/8), bounds2(-1/10, 1/20));
ivmat J = evalJacobianAtBox (I, B); J;
↳ [69/20, 23/5],[-61/40, -27/40]
↳ [67/20, 24/5],[-159/40, -93/40]
↳
list result = ivmatGaussian2(J);

```

```

ivmat Jinv = result[2];
Jinv;
⇒ [1060/4273, 620/187],[-1220/561, -180/4273]
⇒ [2680/12819, 1280/187],[-920/187, -3680/12819]
⇒
Jinv * J;
⇒ [-7657037/799051, 12073835/799051],[-3961862/799051, 6773506/799051]
⇒ [-18293234/799051, 73172936/2397153],[-7807572/799051, 15513600/799051]
⇒
ivmat Jadj = diagMatrix(2, 1/det(J)) * adjunct(J);
Jadj;
⇒ [620/4273, 1060/187],[-1220/561, -180/4273]
⇒ [2680/12819, 1280/187],[-3680/561, -920/4273]
⇒
Jadj * J;
⇒ [-7940903/799051, 20722387/799051],[-6829045/799051, 6829045/799051]
⇒ [-24583090/799051, 24583090/799051],[-7940903/799051, 20722387/799051]
⇒

```

D.8.2.7 evalPolyAtBox2

Procedure from library `interval.lib` (see [Section D.8.2 \[interval.lib\]](#), page 1829).

Usage: `evalPolyAtBox2(f, B)`, `f` poly, `B` box

Return: interval extension `ff(intervals)`

Example:

```

LIB "interval.lib";
ring R = 0,x,lp;
interval I1 = bounds2(0, 1); I1;
⇒ [0, 1]
⇒
poly f = x3 + 4x + 3;
evalPolyAtBox2(f, list(I1));
⇒ [3, 8]
⇒
ring S = 0,(x,y,z),lp;
interval I2 = bounds2(0, 1);
box B = list(I2, I2, I2);
poly f = xyz2 + 2x2 + (3/2)*y3x + z + 1;
evalPolyAtBox2(f, B);
⇒ [1, 13/2]
⇒

```

D.8.2.8 exclusionTest

Procedure from library `interval.lib` (see [Section D.8.2 \[interval.lib\]](#), page 1829).

Usage: exclusion test for roots with interval arithmetic

Return: list of boxes

Example:

```

LIB "interval.lib";
ring R = 0,(x,y),lp;
ideal I = 2x2-xy+2y2-2,2x2-3xy+3y2-2; // V(I) has four elements
interval i = bounds2(-3/2,3/2);
box B = list(i, i);
list result = exclusionTest(I, B, 1/512);
size(result[1]);
↪ 0
size(result[2]);
↪ 4

```

D.8.3 presolve_lib

Library: presolve.lib

Purpose: Pre-Solving of Polynomial Equations

Author: Gert-Martin Greuel, email: greuel@mathematik.uni-kl.de,

Procedures:

D.8.3.1 degreepart

Procedure from library `presolve.lib` (see [Section D.8.3 \[presolve_lib\]](#), page 1833).

Usage: degreepart(id,d1,d2[v]); id=ideal/module, d1,d2=integers, v=intvec

Return: list of size 2,
 _[1]: generators of id of [v-weighted] total degree $\geq d1$ and $\leq d2$ (default: $v = 1, \dots, 1$)
 _[2]: remaining generators of id

Note: if id is of type int/number/poly it is converted to ideal, if id is of type int-mat/matrix/vector to module and then the corresponding generators are computed

Example:

```

LIB "presolve.lib";
ring r=0,(x,y,z),dp;
ideal i=1+x+x2+x3+x4,3,xz+y3+z8;
degreepart(i,0,4);
↪ [1]:
↪   _[1]=x4+x3+x2+x+1
↪   _[2]=3
↪ [2]:
↪   _[1]=z8+y3+xz
module m=[x,y,z],x*[x3,y2,z],[1,x2,z3,0,1];
intvec v=2,3,6;
show(degreepart(m,8,8,v));
↪ // list, 2 element(s):
↪ [1]:
↪   // module, 1 generator(s)
↪ [x4,xy2,xz]
↪ [2]:
↪   // module, 2 generator(s)
↪ [x,y,z]
↪ [1,x2,z3,0,1]

```

D.8.3.2 elimlinearpart

Procedure from library `presolve.lib` (see [Section D.8.3 \[presolve.lib\], page 1833](#)).

Usage: `elimlinearpart(i[,n]);` i =ideal, n =integer,
default: n =`nvars(basing)`

Return: list L with 5 entries:
 $L[1]$: ideal obtained from i by substituting from the first n variables those which appear in a linear part of i , by putting this part into triangular form
 $L[2]$: ideal of variables which have been substituted
 $L[3]$: ideal, j -th element defines substitution of j -th var in $[2]$
 $L[4]$: ideal of variables of basering, eliminated ones are set to 0
 $L[5]$: ideal, describing the map from the basering to itself such that $L[1]$ is the image of i

Note: the procedure always interreduces the ideal i internally w.r.t. ordering `dp`.

Example:

```
LIB "presolve.lib";
ring s=0,(u,x,y,z),dp;
ideal i = u3+y3+z-x,x2y2+z3,y+z+1,y+u;
elimlinearpart(i);
⇒ [1]:
⇒      _[1]=z4+3z3+z2
⇒ [2]:
⇒      _[1]=u
⇒      _[2]=x
⇒      _[3]=y
⇒ [3]:
⇒      _[1]=u-z-1
⇒      _[2]=x-z
⇒      _[3]=y+z+1
⇒ [4]:
⇒      _[1]=0
⇒      _[2]=0
⇒      _[3]=0
⇒      _[4]=z
⇒ [5]:
⇒      _[1]=z+1
⇒      _[2]=z
⇒      _[3]=-z-1
⇒      _[4]=z
```

D.8.3.3 elimpart

Procedure from library `presolve.lib` (see [Section D.8.3 \[presolve.lib\], page 1833](#)).

Usage: `elimpart(i [,n,e]);` i =ideal, n,e =integers
 n : only the first n vars are considered for substitution,
 $e=0$: substitute from linear part of i (same as `elimlinearpart`)
 $e!=0$: eliminate also by direct substitution
(default: $n = \text{nvars(basing)}$, $e = 1$)

Return: list of 5 objects:

- [1]: ideal obtained by substituting from the first n variables those from i , which appear in the linear part of i (or, if $e!=0$, which can be expressed directly in the remaining vars)
- [2]: ideal, variables which have been substituted
- [3]: ideal, i -th element defines substitution of i -th var in [2]
- [4]: ideal of variables of basering, substituted ones are set to 0
- [5]: ideal, describing the map from the basering, say $k[x(1..m)]$, to itself onto $k[..\text{variables from } [4]..]$ and [1] is the image of i

The ideal i is generated by [1] and [3] in $k[x(1..m)]$, the map [5] maps [3] to 0, hence induces an isomorphism

$$k[x(1..m)]/i \rightarrow k[..\text{variables from } [4]..]/[1]$$

Note: Applying `elimpart` to `interred(i)` may result in more substitutions. However, `interred` may be more expansive than `elimpart` for big ideals

Example:

```
LIB "presolve.lib";
ring s=0,(u,x,y,z),dp;
ideal i = xy2-xu4-x+y2,x2y2+z3+zy,y+z2+1,y+u2;
elimpart(i);
↳ [1]:
↳   _[1]=u2-z2-1
↳   _[2]=u12-u2z+z3
↳ [2]:
↳   _[1]=y
↳   _[2]=x
↳ [3]:
↳   _[1]=u2+y
↳   _[2]=-u4+x
↳ [4]:
↳   _[1]=u
↳   _[2]=0
↳   _[3]=0
↳   _[4]=z
↳ [5]:
↳   _[1]=u
↳   _[2]=u4
↳   _[3]=-u2
↳   _[4]=z
i = interred(i); i;
↳ i[1]=z2+y+1
↳ i[2]=y2-x
↳ i[3]=u2+y
↳ i[4]=x3+z3+yz
elimpart(i);
↳ [1]:
↳   _[1]=u2-z2-1
↳   _[2]=u12-u2z+z3
↳ [2]:
↳   _[1]=x
```

```

⇒  _[2]=y
⇒  [3]:
⇒  _[1]=-y2+x
⇒  _[2]=u2+y
⇒  [4]:
⇒  _[1]=u
⇒  _[2]=0
⇒  _[3]=0
⇒  _[4]=z
⇒  [5]:
⇒  _[1]=u
⇒  _[2]=u4
⇒  _[3]=-u2
⇒  _[4]=z
elimpart(i,2);
⇒  [1]:
⇒  _[1]=z2+y+1
⇒  _[2]=u2+y
⇒  _[3]=y6+z3+yz
⇒  [2]:
⇒  _[1]=x
⇒  [3]:
⇒  _[1]=-y2+x
⇒  [4]:
⇒  _[1]=u
⇒  _[2]=0
⇒  _[3]=y
⇒  _[4]=z
⇒  [5]:
⇒  _[1]=u
⇒  _[2]=y2
⇒  _[3]=y
⇒  _[4]=z

```

D.8.3.4 elimpartanyr

Procedure from library `presolve.lib` (see [Section D.8.3 \[presolve.lib\]](#), page 1833).

Usage: `elimpartanyr(i [,p,e]);` `i`=ideal, `p`=polynomial, `e`=integer
`p`: product of vars to be eliminated,
`e` =0: substitute from linear part of `i` (same as `elimlinearpart`)
`e`!=0: eliminate also by direct substitution
(default: `p`=product of all vars, `e`=1)

Return: list of 6 objects:

- [1]: (interreduced) ideal obtained by substituting from `i` those vars appearing in `p`, which occur in the linear part of `i` (or which can be expressed directly in the remaining variables, if `e`!=0)
- [2]: ideal, variables which have been substituted
- [3]: ideal, `i`-th element defines substitution of `i`-th var in [2]
- [4]: ideal of variables of basering, substituted ones are set to 0
- [5]: ideal, describing the map from the basering, say $k[x(1..m)]$, to itself onto $k[..\text{variables from [4]}..]$ and [1] is the image of `i`
- [6]: int, # of vars considered for substitution (= # of factors of `p`)

The ideal i is generated by [1] and [3] in $k[x(1..m)]$, the map [5] maps [3] to 0, hence induces an isomorphism

$$k[x(1..m)]/i \rightarrow k[\text{..variables from [4]..}]/[1]$$

Note: the procedure creates a ring with ordering `dp` and vars placed correctly and then applies `elimpart`.

Example:

```
LIB "presolve.lib";
ring s=0,(x,y,z),dp;
ideal i = x3+y2+z,x2y2+z3,y+z+1;
elimpartanyr(i,z);
⇒ [1]:
⇒   _[1]=x3+y2-y-1
⇒   _[2]=x2y2-y3-3y2-3y-1
⇒ [2]:
⇒   _[1]=z
⇒ [3]:
⇒   _[1]=y+z+1
⇒ [4]:
⇒   _[1]=0
⇒   _[2]=x
⇒   _[3]=y
⇒ [5]:
⇒   _[1]=-y-1
⇒   _[2]=x
⇒   _[3]=y
⇒ [6]:
⇒   1
```

D.8.3.5 fastelim

Procedure from library `presolve.lib` (see [Section D.8.3 \[presolve.lib\]](#), page 1833).

Usage: `fastelim(i,p[h,o,a,b,e,m]);` i =ideal, p =polynomial; h,o,a,b,e =integers

p : product of variables to be eliminated;

Optional parameters:

- $h \neq 0$: use Hilbert-series driven std-basis computation
- $o \neq 0$: use proc `valvars` for a - hopefully - optimal ordering of vars
- $a \neq 0$: order vars to be eliminated w.r.t. increasing complexity
- $b \neq 0$: order vars not to be eliminated w.r.t. increasing complexity
- $e \neq 0$: use `elimpart` first to eliminate easy part
- $m \neq 0$: compute a minimal system of generators

(default: $h,o,a,b,e,m = 0,1,0,0,0,0$)

Return: ideal obtained from i by eliminating those variables, which occur in p

Example:

```
LIB "presolve.lib";
ring s=31991,(e,f,x,y,z,t,u,v,w,a,b,c,d),dp;
ideal i = w2+f2-1, x2+t2+a2-1, y2+u2+b2-1, z2+v2+c2-1,
```

```

d2+e2-1, f4+2u, wa+tf, xy+tu+ab;
fastelim(i,xytua,1,1);          //with hilb,valvars
↳ _[1]=z2+v2+c2-1
↳ _[2]=f2+w2-1
↳ _[3]=e2+d2-1
fastelim(i,xytua,1,0,1);       //with hilb,minbase
↳ _[1]=z2+v2+c2-1
↳ _[2]=f2+w2-1
↳ _[3]=e2+d2-1

```

D.8.3.6 findvars

Procedure from library `presolve.lib` (see [Section D.8.3 \[presolve.lib\]](#), page 1833).

Usage: `findvars(id);` `id=poly/ideal/vector/module/matrix`

Return: list L with 4 entries:
 L[1]: ideal of variables occurring in id
 L[2]: intvec of variables occurring in id
 L[3]: ideal of variables not occurring in id
 L[4]: intvec of variables not occurring in id

Example:

```

LIB "presolve.lib";
ring s = 0,(e,f,x,y,t,u,v,w,a,d),dp;
ideal i = w2+f2-1, x2+t2+a2-1;
findvars(i);
↳ [1]:
↳ _[1]=f
↳ _[2]=x
↳ _[3]=t
↳ _[4]=w
↳ _[5]=a
↳ [2]:
↳ 2,3,5,8,9
↳ [3]:
↳ _[1]=e
↳ _[2]=y
↳ _[3]=u
↳ _[4]=v
↳ _[5]=d
↳ [4]:
↳ 1,4,6,7,10

```

See also: [Section 5.1.166 \[variables\]](#), page 285.

D.8.3.7 hilbvec

Procedure from library `presolve.lib` (see [Section D.8.3 \[presolve.lib\]](#), page 1833).

Usage: `hilbvec(id[,c,o]);` `id=poly/ideal/vector/module/matrix`, `c,o=strings`,
`c=char`, `o=ordering` used by `hilb` (default: `c="32003"`, `o="dp"`)

Return: bigintvec of 1st Hilbert-series of id, computed in char c and ordering o

Note: id must be homogeneous (i.e. all vars have weight 1)

Example:

```
LIB "presolve.lib";
ring s = 0, (e,f,x,y,z,t,u,v,w,a,b,c,d,H), dp;
ideal id = w2+f2-1, x2+t2+a2-1, y2+u2+b2-1, z2+v2+c2-1,
d2+e2-1, f4+2u, wa+tf, xy+tu+ab;
id = homog(id,H);
hilbvec(id);
↪ 1,0,-7,0,20,0,-28,0,14,0,14,0,-28,0,20,0,-7,0,1,0
```

D.8.3.8 linearpart

Procedure from library `presolve.lib` (see [Section D.8.3 \[presolve.lib\], page 1833](#)).

Usage: linearpart(id); id=ideal/module

Return: list of size 2,
 -[1]: generators of id of total degree ≤ 1
 -[2]: remaining generators of id

Note: all variables have degree 1 (independent of ordering of basering)

Example:

```
LIB "presolve.lib";
ring r=0,(x,y,z),dp;
ideal i=1+x+x2+x3,3,x+3y+5z;
linearpart(i);
↪ [1]:
↪ _[1]=3
↪ _[2]=x+3y+5z
↪ [2]:
↪ _[1]=x3+x2+x+1
module m=[x,y,z],x*[x3,y2,z],[1,x2,z3,0,1];
show(linearpart(m));
↪ // list, 2 element(s):
↪ [1]:
↪ // module, 1 generator(s)
↪ [x,y,z]
↪ [2]:
↪ // module, 2 generator(s)
↪ [x4,xy2,xz]
↪ [1,x2,z3,0,1]
```

D.8.3.9 tolessvars

Procedure from library `presolve.lib` (see [Section D.8.3 \[presolve.lib\], page 1833](#)).

Usage: tolessvars(id [,s1,s2]); id poly/ideal/vector/module/matrix, s1=string (new ordering) [default: s1="dp" or "ds" depending on whether the first block of the old ordering is a p- or an s-ordering, respectively]

Return: If id contains all vars of the basering: empty list.
 Else: ring R with the same char as the basering, but possibly less variables (only those variables which actually occur in id). In R an object IMAG (image of id under imap) is stored.

Display: If `printlevel >= 0`, display ideal of vars, which have been omitted from the old ring.

Example:

```
LIB "presolve.lib";
ring r = 0,(x,y,z),dp;
ideal i = y^2-x^3,x-3,y-2x;
def R_r = tolessvars(i,"lp");
↳
↳ // variables which did not occur:
↳ z
↳
↳ // 'tolessvars' created a ring, in which an object IMAG is stored.
↳ // To access the object, type (if the name R was assigned to the return value):
↳      setring R; IMAG;
setring R_r;
show(basing);
↳ // ring: (QQ),(x,y),(lp(2),C);
↳ // minpoly = 0
↳ // objects belonging to this ring:
↳ // IMAG [0] ideal, 3 generator(s)
IMAG;
↳ IMAG[1]=-x^3+y^2
↳ IMAG[2]=x-3
↳ IMAG[3]=-2x+y
kill R_r;
```

D.8.3.10 solvelinearpart

Procedure from library `presolve.lib` (see [Section D.8.3 \[presolve.lib\]](#), page 1833).

Usage: `solverlinearpart(id [,n]);` `id`=ideal/module, `n`=integer (default: `n=0`)

Return: (interreduced) generators of `id` of degree ≤ 1 in reduced triangular form if `n=0` [non-reduced triangular form if `n!=0`]

Assume: monomial ordering is a global ordering (p-ordering)

Note: may be used to solve a system of linear equations, see `gauss_row` from 'matrix.lib' for a different method

Warning: the result is very likely to be false for 'real' coefficients, use `char 0` instead!

Example:

```
LIB "presolve.lib";
// Solve the system of linear equations:
//      3x +  y +  z -  u = 2
//      3x + 8y + 6z - 7u = 1
//      14x + 10y + 6z - 7u = 0
//      7x + 4y + 3z - 3u = 3
ring r = 0,(x,y,z,u),lp;
ideal i= 3x +  y +  z -  u,
13x + 8y + 6z - 7u,
14x + 10y + 6z - 7u,
7x + 4y + 3z - 3u;
ideal j= 2,1,0,3;
```

```

j = matrix(i)-matrix(j);          // difference of 1x4 matrices
// compute reduced triangular form, setting
solvelinearpart(j);              // the RHS equal 0 gives the solutions!
⇨ _[1]=u-4
⇨ _[2]=z-4
⇨ _[3]=y+1
⇨ _[4]=x-1
solvelinearpart(j,1); "";        // triangular form, not reduced
⇨ _[1]=u-4
⇨ _[2]=2z-u-4
⇨ _[3]=11y+5z-8u+23
⇨ _[4]=3x+y+z-u-2
⇨

```

D.8.3.11 sortandmap

Procedure from library `presolve.lib` (see [Section D.8.3 \[presolve.lib\]](#), page 1833).

Usage: `sortandmap(id [,n1,p1,n2,p2...,o1,m1,o2,m2...]);`
`id=poly/ideal/vector/module,`
`p1,p2,...= polynomials (product of variables),`
`n1,n2,...= integers,`
`o1,o2,...= strings,`
`m1,m2,...= integers`
(default: `p1=product of all vars, n1=0, o1="dp",m1=0`)
the last `pi` (containing the remaining vars) may be omitted

Return: a ring `R`, in which a `poly/ideal/vector/module` `IMAG` is stored:
- the ring `R` differs from the active basering only in the choice of monomial ordering and in the sorting of the variables.
- `IMAG` is the image (under `imap`) of the input `ideal/module id`
The new monomial ordering and sorting of vars is as follows:
- each block of vars occurring in `pi` is sorted w.r.t. its complexity in `id`,
- `ni` controls the sorting in `i`-th block (= vars occurring in `pi`):
`ni=0` (resp. `ni!=0`) means that least complex (resp. most complex) vars come first
- `oi` and `mi` define the monomial ordering of the `i`-th block:
if `mi =0`, `oi=ordstr(i-th block)`
if `mi!=0`, the ordering of the `i`-th block itself is a blockordering,
each subblock having `ordstr=oi`, such that vars of same complexity are in one block

Note that only simple ordstrings `oi` are allowed: `"lp","dp","Dp", "ls","ds","Ds"`.

Note: We define a variable `x` to be more complex than `y` (with respect to `id`) if `val(x) > val(y)` lexicographically, where `val(x)` denotes the valuation vector of `x`:
consider `id` as list of polynomials in `x` with coefficients in the remaining variables. Then:
`val(x) = (maximal occurring power of x, # of all monomials in leading coefficient, # of all monomials in coefficient of next smaller power of x,...)`.

Example:

```
LIB "presolve.lib";
```

```

ring s = 32003,(x,y,z),dp;
ideal i=x3+y2,xz+z2;
def R_r=sortandmap(i);
↳
↳ // 'sortandmap' created a ring, in which an object IMAG is stored.
↳ // To access the object, type (if the name R was assigned to the return v\
    alue):

kill R_r;

```

D.8.3.12 sortvars

Procedure from library `presolve.lib` (see [Section D.8.3 \[presolve.lib\]](#), page 1833).

Usage: `sortvars(id[,n1,p1,n2,p2,...]);`
 `id=poly/ideal/vector/module,`
 `p1,p2,...= polynomials (product of vars),`
 `n1,n2,...= integers`
 (default: `p1=product of all vars, n1=0`)
 the last `pi` (containing the remaining vars) may be omitted

Compute: sort variables with respect to their complexity in `id`

Return: list of two elements, an ideal and a list:

- [1]: ideal, variables of basering sorted w.r.t their complexity in `id`
 `ni` controls the ordering in `i`-th block (= vars occurring in `pi`):
 `ni=0` (resp. `ni!=0`) means that less (resp. more) complex vars come first
- [2]: a list with 4 entries for each `pi`:
 - [1]: ideal `ai` : vars of `pi` in correct order,
 - [2]: intvec `vi`: permutation vector describing the ordering in `ai`,
 - [3]: intmat `Mi`: valuation matrix of `ai`, the columns of `Mi` being the

valuation vectors of the vars in a_i
 $_{-}[4]$: intvec w_i : size of 1-st, 2-nd,... block of identical columns of M_i
 (vars with same valuation)

Note: We define a variable x to be more complex than y (with respect to id) if $\text{val}(x) > \text{val}(y)$ lexicographically, where $\text{val}(x)$ denotes the valuation vector of x :
 consider id as list of polynomials in x with coefficients in the remaining variables. Then:
 $\text{val}(x) = (\text{maximal occurring power of } x, \# \text{ of all monomials in leading coefficient, } \# \text{ of all monomials in coefficient of next smaller power of } x, \dots)$.

Example:

```
LIB "presolve.lib";
ring s=0,(x,y,z,w),dp;
ideal i = x3+y2+yw2,xz+z2,xyz-w2;
sortvars(i,0,xy,1,zw);
↳ [1]:
↳   _[1]=x
↳   _[2]=y
↳   _[3]=z
↳   _[4]=w
↳ [2]:
↳   [1]:
↳     _[1]=y
↳     _[2]=x
↳   [2]:
↳     2,1
↳   [3]:
↳     2,3,
↳     1,1,
↳     2,0,
↳     0,2
↳   [4]:
↳     1,1
↳   [5]:
↳     _[1]=w
↳     _[2]=z
↳   [6]:
↳     2,1
↳   [7]:
↳     2,2,
↳     2,1,
↳     0,2
↳   [8]:
↳     1,1
```

D.8.3.13 valvars

Procedure from library `presolve.lib` (see [Section D.8.3 \[presolve.lib\]](#), page 1833).

Usage: `valvars(id[,n1,p1,n2,p2,...]);`
 id =poly/ideal/vector/module,
 $p1,p2,\dots$ = polynomials (product of vars),
 $n1,n2,\dots$ = integers,

ni controls the ordering of vars occurring in pi: ni=0 (resp. ni!=0) means that less (resp. more) complex vars come first (default: p1=product of all vars, n1=0), the last pi (containing the remaining vars) may be omitted

Compute: valuation (complexity) of variables with respect to id.
 ni controls the ordering of vars occurring in pi:
 ni=0 (resp. ni!=0) means that less (resp. more) complex vars come first.

Return: list with 3 entries:
 [1]: intvec, say v, describing the permutation such that the permuted ring variables are ordered with respect to their complexity in id
 [2]: list of intvecs, i-th intvec, say v(i) describing permutation of vars in a(i) such that $v=v(1), v(2), \dots$
 [3]: list of ideals and intmat's, say a(i) and M(i), where
 a(i): factors of pi,
 M(i): valuation matrix of a(i), such that the j-th column of M(i) is the valuation vector of j-th generator of a(i)

Note: Use `sortvars` in order to actually sort the variables! We define a variable x to be more complex than y (with respect to id) if $\text{val}(x) > \text{val}(y)$ lexicographically, where $\text{val}(x)$ denotes the valuation vector of x:
 consider id as list of polynomials in x with coefficients in the remaining variables. Then:
 $\text{val}(x) = (\text{maximal occurring power of } x, \# \text{ of all monomials in leading coefficient, } \# \text{ of all monomials in coefficient of next smaller power of } x, \dots)$.

Example:

```
LIB "presolve.lib";
ring s=0,(x,y,z,a,b),dp;
ideal i=ax2+ay3-b2x,abz+by2;
valvars (i,0,xyz);
⇒ [1]:
⇒ 1,2,3,4,5
⇒ [2]:
⇒ [1]:
⇒ 3,1,2
⇒ [2]:
⇒ 1,2
⇒ [3]:
⇒ [1]:
⇒ _[1]=x
⇒ _[2]=y
⇒ _[3]=z
⇒ [2]:
⇒ 2,3,1,
⇒ 1,1,1,
⇒ 1,1,0
⇒ [3]:
⇒ _[1]=a
⇒ _[2]=b
⇒ [4]:
⇒ 1,2,
⇒ 3,1,
⇒ 0,2
```

D.8.3.14 idealSplit

Procedure from library `presolve.lib` (see [Section D.8.3 \[presolve.lib\]](#), page 1833).

Usage: `idealSplit(id,timeF,timeS);` `id` ideal and optional
`timeF`, `timeS` integers to bound the time which can be used for factorization resp.
 standard basis computation

Return: a list of ideals such that their intersection
 has the same radical as `id`

Example:

```
LIB "presolve.lib";
ring r=32003,(b,s,t,u,v,w,x,y,z),dp;
ideal i=
bv+su,
bw+tu,
sw+tv,

```

D.8.4 solve_lib

Library: solve.lib

Purpose: Complex Solving of Polynomial Systems

Author: Moritz Wenk, email: wenk@mathematik.uni-kl.de
 Wilfred Pohl, email: pohl@mathematik.uni-kl.de

Procedures:

D.8.4.1 laguerre_solve

Procedure from library `solve.lib` (see [Section D.8.4 \[solve.lib\]](#), page 1847).

Usage: laguerre_solve(f [, m, l, n, s]); f = polynomial,
 m, l, n, s = integers (control parameters of the method)
 m: precision of output in digits (4 <= m), if basering is not ring of complex numbers;
 l: precision of internal computation in decimal digits (l >= 8) only if the basering is
 not complex or complex with smaller precision;
 n: control of multiplicity of roots or of splitting of f into squarefree factors
 n < 0, no split of f (good, if all roots are simple)
 n >= 0, try to split
 n = 0, return only different roots
 n > 0, find all roots (with multiplicity)
 s: s != 0, returns ERROR if | f(root) | > 0.1^m (when computing in the current ring)
 (default: m, l, n, s = 8, 30, 1, 0)

Assume: f is a univariate polynomial;
 basering has characteristic 0 and is either complex or without parameters.

Return: list of (complex) roots of the polynomial f , depending on n . The entries of the result are of type
 string: if the basering is not complex,
 number: otherwise.

Note: If `printlevel > 0`: displays comments (default = 0).
 If `s != 0` and if the procedure stops with ERROR, try a higher internal precision `m`.

Example:

```
LIB "solve.lib";
// Find all roots of an univariate polynomial using Laguerre's method:
ring rs1= 0,(x,y),lp;
poly f = 15x5 + x3 + x2 - 10;
// 10 digits precision
laguerre_solve(f,10);
⇒ [1]:
⇒ 0.8924637479
⇒ [2]:
⇒ (-0.7392783383+i*0.5355190078)
⇒ [3]:
⇒ (-0.7392783383-i*0.5355190078)
⇒ [4]:
⇒ (0.2930464644-i*0.9003002396)
⇒ [5]:
⇒ (0.2930464644+i*0.9003002396)
// Now with complex coefficients,
// internal precision is 30 digits (default)
printlevel=2;
ring rsc= (real,10,i),x,lp;
poly f = (15.4+i*5)*x^5 + (25.0e-2+i*2)*x^3 + x2 - 10*i;
list l = laguerre_solve(f);
⇒ //BEGIN laguerre_solve
⇒ //control: complex ring with precision 30
⇒ //working in: complex,10,10,i
⇒ // polynomial has complex coefficients
⇒ //split in working ring:
⇒ //split without result
⇒ //END laguerre_solve
l;
⇒ [1]:
⇒ (-0.8557376852+i*0.3557664188)
⇒ [2]:
⇒ (-0.5462895588-i*0.6796668873)
⇒ [3]:
⇒ (0.04588498039+i*0.9133296179)
⇒ [4]:
⇒ (0.5037408279-i*0.8058051828)
⇒ [5]:
⇒ (0.8524014357+i*0.2163760334)
// check result, value of substituted polynomial should be near to zero
// remember that l contains a list of strings
// in the case of a different ring
subst(f,x,l[1]);
⇒ 0
```

```
subst(f,x,l[2]);
↦ 0
```

D.8.4.2 solve

Procedure from library `solve.lib` (see [Section D.8.4 \[solve.lib\], page 1847](#)).

Usage: `solve(G [, m, n [, l]] [, "oldring"] [, "nodisplay"]);` G = ideal, m, n, l = integers (control parameters of the method), `outR` ring,
 m : precision of output in digits ($4 \leq m$) and of the generated ring of complex numbers;
 n : control of multiplicity
 $n = 0$, return all different roots
 $n \neq 0$, find all roots (with multiplicity)
 l : precision of internal computation in decimal digits ($l \geq 8$) only if the basering is not complex or complex with smaller precision,
[default: $(m,n,l) = (8,0,30)$, or if only (m,n) are set explicitly with $n \neq 0$, then $(m,n,l) = (m,n,60)$]

Assume: the ideal is 0-dimensional;
basing has characteristic 0 and is either complex or without parameters;

Return: (1) If called without the additional parameter `"oldring"`:
ring R with the same number of variables but with complex coefficients (and precision m). R comes with a list `SOL` of numbers, in which complex roots of G are stored:
* If $n = 0$, `SOL` is the list of all different solutions, each of them being represented by a list of numbers.
* If $n \neq 0$, `SOL` is a list of two list: `SOL[i][1]` is the list of all different solutions with the multiplicity `SOL[i][2]`.
`SOL` is ordered w.r.t. multiplicity (the smallest first).
(2) If called with the additional parameter `"oldring"`, the procedure looks for an appropriate ring (at top level) in which the solutions can be stored (interactive).
The user may then select an appropriate ring and choose a name for the output list in this ring. The list is exported directly to the selected ring and the return value is a string "result exported to" + name of the selected ring.

Note: If the problem is not 0-dim. the procedure stops with ERROR. If the ideal G is not a lexicographic Groebner basis, the lexicographic Groebner basis is computed internally (Hilbert driven).
The computed solutions are displayed, unless `solve` is called with the additional parameter `"nodisplay"`.

Example:

```
LIB "solve.lib";
// Find all roots of a multivariate ideal using triangular sets:
int d,t,s = 4,3,2 ;
int i;
ring A=0,x(1..d),dp;
poly p=-1;
for (i=d; i>0; i--) { p=p+x(i)^s; }
ideal I = x(d)^t-x(d)^s+p;
for (i=d-1; i>0; i--) { I=x(i)^t-x(i)^s+p,I; }
I;
↦ I[1]=x(1)^3+x(2)^2+x(3)^2+x(4)^2-1
```

```

⇒ I[2]=x(2)^3+x(1)^2+x(3)^2+x(4)^2-1
⇒ I[3]=x(3)^3+x(1)^2+x(2)^2+x(4)^2-1
⇒ I[4]=x(4)^3+x(1)^2+x(2)^2+x(3)^2-1
// the multiplicity is
vdim(std(I));
⇒ 81
def AC=solve(I,6,0,"nodisplay"); // solutions should not be displayed
⇒
⇒ // 'solve' created a ring, in which a list SOL of numbers (the complex so\
  lutions)
⇒ // is stored.
⇒ // To access the list of complex solutions, type (if the name R was assign\
  ed
⇒ // to the return value):
⇒      setring R; SOL;
// list of solutions is stored in AC as the list SOL (default name)
setring AC;
size(SOL); // number of different solutions
⇒ 37
SOL[5]; // the 5th solution
⇒ [1]:
⇒ 0.587401
⇒ [2]:
⇒ -0.32748
⇒ [3]:
⇒ 0.587401
⇒ [4]:
⇒ 0.587401
// you must start with char. 0
setring A;
def AC1=solve(I,6,1,"nodisplay");
⇒
⇒ // 'solve' created a ring, in which a list SOL of numbers (the complex so\
  lutions)
⇒ // is stored.
⇒ // To access the list of complex solutions, type (if the name R was assign\
  ed
⇒ // to the return value):
⇒      setring R; SOL;
setring AC1;
size(SOL); // number of different multiplicities

⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 0
⇒ [3]:
⇒ 1
⇒ [4]:
⇒ 0
SOL[2][2];             // multiplicity 12
⇒ 12
// the number of different solutions is equal to
size(SOL[1][1])+size(SOL[2][1]);
⇒ 37
// the number of complex solutions (counted with multiplicities) is
size(SOL[1][1])*SOL[1][2]+size(SOL[2][1])*SOL[2][2];
⇒ 81

```

D.8.4.3 ures_solve

Procedure from library `solve.lib` (see [Section D.8.4 \[solve.lib\]](#), page 1847).

- Usage:** `ures_solve(i [, k, p]);` i = ideal, k, p = integers
 $k=0$: use sparse resultant matrix of Gelfand, Kapranov and Zelevinsky,
 $k=1$: use resultant matrix of Macaulay which works only for homogeneous ideals,
 $p>0$: defines precision of the long floats for internal computation if the basering is not complex (in decimal digits),
(default: $k=0, p=30$)
- Assume:** i is a zerodimensional ideal given by a quadratic system, that is,
 $\text{nvars}(\text{basing}) = \text{ncols}(i) =$ number of vars actually occurring in i ,
- Return:** If the ground field is the field of complex numbers: list of numbers (the complex roots of the polynomial system $i=0$).
Otherwise: ring R with the same number of variables but with complex coefficients (and precision p). R comes with a list `SOL` of numbers, in which complex roots of the polynomial system i are stored:

Example:

```

LIB "solve.lib";
// compute the intersection points of two curves
ring rsq = 0,(x,y),lp;
ideal gls= x2 + y2 - 10, x2 + xy + 2y2 - 16;
def R=ures_solve(gls,0,16);
⇒
⇒ // 'ures_solve' created a ring, in which a list SOL of numbers (the compl\
ex
⇒ // solutions) is stored.
⇒ // To access the list of complex solutions, type (if the name R was assign\
ed
⇒ // to the return value):
⇒      setring R; SOL;
setring R; SOL;

```

```

⇒ -2.82842712474619
⇒ [2]:
⇒ -1.414213562373095
⇒ [2]:
⇒ [1]:
⇒ -1
⇒ [2]:
⇒ 3
⇒ [3]:
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ -3
⇒ [4]:
⇒ [1]:
⇒ 2.82842712474619
⇒ [2]:
⇒ 1.414213562373095

```

D.8.4.4 mp_res_mat

Procedure from library `solve.lib` (see [Section D.8.4 \[solve.lib\]](#), page 1847).

Usage: `mp_res_mat(i [, k]);` `i` ideal, `k` integer,
`k=0`: sparse resultant matrix of Gelfand, Kapranov and Zelevinsky,
`k=1`: resultant matrix of Macaulay (`k=0` is default)

Assume: The number of elements in the input system must be the number of variables in the basering plus one;
if `k=1` then `i` must be homogeneous.

Return: module representing the multipolynomial resultant matrix

Example:

```

LIB "solve.lib";
// compute resultant matrix in ring with parameters (sparse resultant matrix)
ring rsq= (0,u0,u1,u2),(x1,x2),lp;
ideal i= u0+u1*x1+u2*x2,x1^2 + x2^2 - 10,x1^2 + x1*x2 + 2*x2^2 - 16;
module m = mp_res_mat(i);
print(m);
⇒ -16,0, -10,0, (u0),0, 0, 0, 0, 0,
⇒ 0, -16,0, -10,(u2),(u0),0, 0, 0, 0,
⇒ 2, 0, 1, 0, 0, (u2),0, 0, 0, 0,
⇒ 0, 2, 0, 1, 0, 0, 0, 0, 0, 0,
⇒ 0, 0, 0, 0, (u1),0, -10,(u0),0, -16,
⇒ 1, 0, 0, 0, 0, (u1),0, (u2),(u0),0,
⇒ 0, 1, 0, 0, 0, 0, 1, 0, (u2),2,
⇒ 1, 0, 1, 0, 0, 0, 0, (u1),0, 0,
⇒ 0, 1, 0, 1, 0, 0, 0, 0, (u1),1,
⇒ 0, 0, 0, 0, 0, 0, 1, 0, 0, 1
// computing sparse resultant
det(m);
⇒ (-2*u0^4+18*u0^2*u1^2+4*u0^2*u1*u2+22*u0^2*u2^2-16*u1^4+80*u1^3*u2-52*u1^2

```

```

2*u2^2-120*u1*u2^3-36*u2^4)
// compute resultant matrix (Macaulay resultant matrix)
ring rdq= (0,u0,u1,u2),(x0,x1,x2),lp;
ideal h= homog(imap(rsq,i),x0);

D.8.4.5 interpolate

Procedure from library `solve.lib` (see [Section D.8.4 \[solve.lib\]](#), page 1847).

Usage: `interpolate(p,v,d)`; p,v =ideals of numbers, d =integer

Assume: Ground field K is the field of rational numbers, p and v are lists of elements of the ground field K with $p[j] \neq -1,0,1$, $\text{size}(p) = n$ (= number of vars) and $\text{size}(v)=N=(d+1)^n$.

Return: poly f , the unique polynomial f of degree $n*d$ with prescribed values $v[i]$ at the points $p(i)=(p[1]^{(i-1)},\dots,p[n]^{(i-1)})$, $i=1,\dots,N$.

Note: mainly useful when $n=1$, i.e. f is satisfying $f(p^{(i-1)}) = v[i]$, $i=1..d+1$.

Example:

```
LIB "solve.lib";
ring r1 = 0,(x),lp;
// determine f with deg(f) = 4 and
// v = values of f at points 3^0, 3^1, 3^2, 3^3, 3^4
ideal v=16,0,11376,1046880,85949136;
interpolate( 3, v, 4 );
↳ 2x4-22x2+36
```

See also: [Section 5.1.164 \[vandermonde\]](#), page 284.

D.8.4.6 fglm_solve

Procedure from library `solve.lib` (see [Section D.8.4 \[solve.lib\]](#), page 1847).

Usage: `fglm_solve(i [, p]);` i ideal, p integer

Assume: the ground field has char 0.

Return: ring R with the same number of variables but with complex coefficients (and precision p). R comes with a list `rlist` of numbers, in which the complex roots of i are stored.
 $p>0$: gives precision of complex numbers in decimal digits [default: $p=30$].

Note: The procedure uses a standard basis of i to determine all complex roots of i .

Example:

```
LIB "solve.lib";
ring r = 0,(x,y),dp;
// compute the intersection points of two curves
ideal s = x2 + y2 - 10, x2 + xy + 2y2 - 16;
def R = fglm_solve(s,10);
↳
↳ // 'fglm_solve' created a ring, in which a list rlist of numbers (the
↳ // complex solutions) is stored.
↳ // To access the list of complex solutions, type (if the name R was assign\
    ned
↳ // to the return value):
↳      setring R; rlist;
setring R; rlist;
↳ [1]:
↳      [1]:
↳      1
↳      [2]:
↳      -3

↳ [3]:
↳      [1]:
↳      2.828427125
↳      [2]:
↳      1.414213562
```

```

⇒ [4]:
⇒ [1]:
⇒ -1
⇒ [2]:
⇒ 3

```

D.8.4.7 lex_solve

Procedure from library `solve.lib` (see [Section D.8.4 \[solve.lib\]](#), page 1847).

Usage: `lex_solve(i[p]);` i =ideal, p =integer,
 $p > 0$: gives precision of complex numbers in decimal digits (default: $p=30$).

Assume: i is a reduced lexicographical Groebner bases of a zero-dimensional ideal, sorted by increasing leading terms.

Return: ring R with the same number of variables but with complex coefficients (and precision p). R comes with a list `rlist` of numbers, in which the complex roots of i are stored.

Example:

```

LIB "solve.lib";
ring r = 0,(x,y),lp;
// compute the intersection points of two curves
ideal s = x2 + y2 - 10, x2 + xy + 2y2 - 16;
def R = lex_solve(stdfglm(s),10);
⇒
⇒ // 'lex_solve' created a ring, in which a list rlist of numbers (the
⇒ // complex solutions) is stored.
⇒ // To access the list of complex solutions, type (if the name R was assign\
    ned
⇒ // to the return value):
⇒          setring R; rlist;

⇒ [2]:
⇒ 3

```

D.8.4.8 simplexOut

Procedure from library `solve.lib` (see [Section D.8.4 \[solve.lib\]](#), page 1847).

Usage: `simplexOut(l); l list`

Assume: `l` is the output of `simplex`.

Return: Nothing. The procedure prints the computed solution of `simplex` (as strings) in a nice format.

Example:

```
LIB "solve.lib";
ring r = (real,10),(x),lp;
// consider the max. problem:
//
//      maximize  x(1) + x(2) + 3*x(3) - 0.5*x(4)
//
// with constraints:  x(1) +          2*x(3)          <= 740
//                   2*x(2)          - 7*x(4) <= 0
//                   x(2) - x(3) + 2*x(4) >= 0.5
//                   x(1) + x(2) + x(3) + x(4) = 9
//
matrix sm[5][5]= 0, 1, 1, 3,-0.5,
740,-1, 0,-2, 0,
0, 0,-2, 0, 7,
0.5, 0,-1, 1,-2,
9,-1,-1,-1,-1;
int n = 4; // number of constraints
int m = 4; // number of variables
int m1= 2; // number of <= constraints
int m2= 1; // number of >= constraints
int m3= 1; // number of == constraints
list sol=simplex(sm, n, m, m1, m2, m3);
simplexOut(sol);
↪ z = 17.025
↪ x2 = 3.325
↪ x4 = 0.95
↪ x3 = 4.725
```

See also: [Section 5.1.142 \[simplex\]](#), page 261.

D.8.4.9 triangLf_solve

Procedure from library `solve.lib` (see [Section D.8.4 \[solve.lib\]](#), page 1847).

Usage: `triangLf_solve(i [, p]); i ideal, p integer,
p>0: gives precision of complex numbers in digits (default: p=30).`

Assume: the ground field has char 0; `i` is a zero-dimensional ideal

Return: ring `R` with the same number of variables but with complex coefficients (and precision `p`). `R` comes with a list `rlist` of numbers, in which the complex roots of `i` are stored.

Note: The procedure uses a triangular system (Lazard's Algorithm with factorization) computed from a standard basis to determine recursively all complex roots of the input ideal `i` with Laguerre's algorithm.

Example:

```

LIB "solve.lib";
ring r = 0,(x,y),lp;
// compute the intersection points of two curves
ideal s = x2 + y2 - 10, x2 + xy + 2y2 - 16;
def R = triangLf_solve(s,10);
⇒
⇒ // 'triangLf_solve' created a ring, in which a list rlist of numbers (the
⇒ // complex solutions) is stored.
⇒ // To access the list of complex solutions, type (if the name R was assign\
    ned
⇒ // to the return value):
⇒      setring R; rlist;
setring R; rlist;
⇒ [1]:
⇒      [1]:
⇒      -1
⇒      [2]:
⇒      3
⇒ [2]:
⇒      [1]:
⇒      1
⇒      [2]:
⇒      -3
⇒ [3]:
⇒      [1]:
⇒      -2.828427125
⇒      [2]:
⇒      -1.414213562
⇒ [4]:
⇒      [1]:
⇒      2.828427125
⇒      [2]:
⇒      1.414213562

```

D.8.4.10 triangM_solve

Procedure from library `solve.lib` (see [Section D.8.4 \[solve.lib\]](#), page 1847).

Usage: `triangM_solve(i [, p])`; `i`=ideal, `p`=integer,
 `p>0`: gives precision of complex numbers in digits (default: `p=30`).

Assume: the ground field has char 0;
 `i` zero-dimensional ideal

Return: ring `R` with the same number of variables but with complex coefficients (and precision `p`). `R` comes with a list `rlist` of numbers, in which the complex roots of `i` are stored.

Note: The procedure uses a triangular system (Moellers Algorithm) computed from a standard basis of input ideal `i` to determine recursively all complex roots with Laguerre's algorithm.

Example:

```

LIB "solve.lib";
ring r = 0,(x,y),lp;

```

```

// compute the intersection points of two curves
ideal s = x2 + y2 - 10, x2 + xy + 2y2 - 16;
def R = triangM_solve(s,10);
↳
↳ // 'triangM_solve' created a ring, in which a list rlist of numbers (the
↳ // complex solutions) is stored.
↳ // To access the list of complex solutions, type (if the name R was assign\
    ned
↳ // to the return value):
↳      setring R; rlist;
setring R; rlist;
↳ [1]:
↳      [1]:
↳      1
↳      [2]:
↳      -3
↳ [2]:

↳      -2.828427125
↳      [2]:
↳      -1.414213562
↳ [3]:
↳      [1]:
↳      2.828427125
↳      [2]:
↳      1.414213562
↳ [4]:
↳      [1]:
↳      -1
↳      [2]:
↳      3

```

D.8.4.11 triangL_solve

Procedure from library `solve.lib` (see [Section D.8.4 \[solve.lib\], page 1847](#)).

Usage: `triangL_solve(i [, p]);` i =ideal, p =integer,
 $p > 0$: gives precision of complex numbers in digits (default: $p=30$).

Assume: the ground field has char 0; i is a zero-dimensional ideal.

Return: ring R with the same number of variables, but with complex coefficients (and precision p). R comes with a list `rlist` of numbers, in which the complex roots of i are stored.

Note: The procedure uses a triangular system (Lazard's Algorithm) computed from a standard basis of input ideal i to determine recursively all complex roots with Laguerre's algorithm.

Example:

```

LIB "solve.lib";
ring r = 0,(x,y),lp;
// compute the intersection points of two curves
ideal s = x2 + y2 - 10, x2 + xy + 2y2 - 16;
def R = triangL_solve(s,10);
↳

```

```

⇒ // 'triangL_solve' created a ring, in which a list rlist of numbers (the
⇒ // complex solutions) is stored.
⇒ // To access the list of complex solutions, type (if the name R was assign\
    ned
⇒ // to the return value):
⇒      setring R; rlist;

```

D.8.4.12 triang_solve

Procedure from library `solve.lib` (see [Section D.8.4 \[solve.lib\]](#), page 1847).

- Usage:** `triang_solve(l,p [,d]);` l =list, p,d =integers
 l is a list of finitely many triangular systems, such that the union of their varieties equals the variety of the initial ideal.
 $p > 0$: gives precision of complex numbers in digits,
 $d > 0$: gives precision ($1 < d < p$) for near-zero-determination,
(default: $d = 1/2 * p$).
- Assume:** the ground field has char 0;
 l was computed using the algorithm of Lazard or the algorithm of Moeller (see `triang.lib`).
- Return:** ring R with the same number of variables, but with complex coefficients (and precision p). R comes with a list `rlist` of numbers, in which the complex roots of l are stored.

Example:

```

LIB "solve.lib";
ring r = 0,(x,y),lp;
// compute the intersection points of two curves
ideal s= x2 + y2 - 10, x2 + xy + 2y2 - 16;
def R=triang_solve(triangLfak(stdfglm(s)),10);
⇒

```

```

⇒ // 'triang_solve' created a ring, in which a list rlist of numbers (the
⇒ // complex solutions) is stored.
⇒ // To access the list of complex solutions, type (if the name R was assign\
    ned
⇒ // to the return value):

⇒      [2]:
⇒      1.414213562

```

D.8.5 triang_lib

Library: triang.lib

Purpose: Decompose Zero-dimensional Ideals into Triangular Sets

Author: D. Hillebrand

Procedures:

D.8.5.1 triangL

Procedure from library `triang.lib` (see [Section D.8.5 \[triang_lib\]](#), page 1860).

Usage: triangL(G); G=ideal

Assume: G is the reduced lexicographical Groebner basis of the zero-dimensional ideal (G), sorted by increasing leading terms.

Return: a list of finitely many triangular systems, such that the union of their varieties equals the variety of (G).

Note: Algorithm of Lazard (see: Lazard, D.: Solving zero-dimensional algebraic systems, J. Symb. Comp. 13, 117 - 132, 1992).

Example:

```

LIB "triang.lib";
ring rC5 = 0,(e,d,c,b,a),lp;

```

```

triangL(stdfglm(cyclic(5)));
⇒ [1]:
⇒   _[1]=a5-1
⇒   _[2]=b-a
⇒   _[3]=c2+3ca+a2
⇒   _[4]=d+c+3a
⇒   _[5]=e-a
⇒ [2]:
⇒   _[1]=a5-1
⇒   _[2]=b-a
⇒   _[3]=c-a
⇒   _[4]=d2+3da+a2
⇒   _[5]=e+d+3a
⇒ [3]:
⇒   _[1]=a5-1
⇒   _[2]=b6+4b5a+5b4a2+5b3a3+5b2a4+4b+a
⇒   _[3]=5c+8b5a+30b4a2+30b3a3+25b2a4+30b+22a
⇒   _[4]=5d-2b5a-10b4a2-15b3a3-10b2a4-10b-8a
⇒   _[5]=5e-6b5a-20b4a2-15b3a3-15b2a4-15b-9a
⇒ [4]:
⇒   _[1]=a10+123a5+1
⇒   _[2]=55b2-2ba6-233ba-8a7-987a2
⇒   _[3]=55c+a6+144a
⇒   _[4]=55d+a6+144a
⇒   _[5]=55e+55b-2a6-233a

```

D.8.5.2 triangLfak

Procedure from library `triang.lib` (see [Section D.8.5 \[triang.lib\]](#), page 1860).

Usage: `triangLfak(G); G=ideal`

Assume: `G` is the reduced lexicographical Groebner basis of the zero-dimensional ideal (`G`), sorted by increasing leading terms.

Return: a list of finitely many triangular systems, such that the union of their varieties equals the variety of (`G`).

Note: Algorithm of Lazard with factorization (see: Lazard, D.: Solving zero-dimensional algebraic systems, J. Symb. Comp. 13, 117 - 132, 1992).

Remark: each polynomial of the triangular systems is factorized.

Example:

```

LIB "triang.lib";
ring rC5 = 0,(e,d,c,b,a),lp;
triangLfak(stdfglm(cyclic(5)));
⇒ [1]:
⇒   _[1]=a-1
⇒   _[2]=b-1
⇒   _[3]=c-1
⇒   _[4]=d2+3d+1
⇒   _[5]=e+d+3
⇒ [2]:
⇒   _[1]=a-1
⇒   _[2]=b-1

```

```

⇒  _[3]=c2+3c+1
⇒  _[4]=d+c+3
⇒  _[5]=e-1
⇒  [3]:

```

D.8.5.3 triangM

Procedure from library `triang.lib` (see [Section D.8.5 \[triang.lib\]](#), page 1860).

Usage: `triangM(G[i]);` G =ideal, i =integer,

Assume: G is the reduced lexicographical Groebner basis of the zero-dimensional ideal (G) , sorted by increasing leading terms.

Return: a list of finitely many triangular systems, such that the union of their varieties equals the variety of (G) . If $i = 2$, then each polynomial of the triangular systems is factorized.

Note: Algorithm of Moeller (see: Moeller, H.M.: On decomposing systems of polynomial equations with finitely many solutions, Appl. Algebra Eng. Commun. Comput. 4, 217 - 230, 1993).

Example:

```

LIB "triang.lib";
ring rC5 = 0,(e,d,c,b,a),lp;
triangM(stdfglm(cyclic(5))); //oder: triangM(stdfglm(cyclic(5)),2);
⇒ [1]:
⇒ _[1]=a5-1
⇒ _[2]=b-a
⇒ _[3]=c-a

⇒ _[4]=5d-2b5a-10b4a2-15b3a3-10b2a4-10b-8a

```

```

⇒      _[5]=5e-6b5a-20b4a2-15b3a3-15b2a4-15b-9a
⇒ [4]:
⇒      _[1]=a5-1
⇒      _[2]=b-a
⇒      _[3]=c2+3ca+a2
⇒      _[4]=d+c+3a
⇒      _[5]=e-a

```

D.8.5.4 triangMH

Procedure from library `triang.lib` (see [Section D.8.5 \[triang.lib\]](#), page 1860).

Usage: `triangMH(G[i]);` G=ideal, i=integer

Assume: G is the reduced lexicographical Groebner basis of the zero-dimensional ideal (G), sorted by increasing leading terms.

Return: a list of finitely many triangular systems, such that the disjoint union of their varieties equals the variety of (G). If $i = 2$, then each polynomial of the triangular systems is factorized.

Note: Algorithm of Moeller and Hillebrand (see: Moeller, H.M.: On decomposing systems of polynomial equations with finitely many solutions, Appl. Algebra Eng. Commun. Comput. 4, 217 - 230, 1993 and Hillebrand, D.: Triangulierung nulldimensionaler Ideale - Implementierung und Vergleich zweier Algorithmen, master thesis, Universitaet Dortmund, Fachbereich Mathematik, Prof. Dr. H.M. Moeller, 1999).

Example:

```

LIB "triang.lib";
ring rC5 = 0,(e,d,c,b,a),lp;
triangMH(stdfglm(cyclic(5)));
⇒ [1]:
⇒      _[1]=a5-1
⇒      _[2]=b-a
⇒      _[3]=c-a
⇒      _[4]=d2+3da+a2
⇒      _[5]=e+d+3a
⇒ [2]:
⇒      _[1]=a10+123a5+1
⇒      _[2]=55b2-2ba6-233ba-8a7-987a2
⇒      _[3]=55c+a6+144a
⇒      _[4]=55d+a6+144a
⇒      _[5]=55e+55b-2a6-233a
⇒ [3]:
⇒      _[1]=a5-1
⇒      _[2]=b6+4b5a+5b4a2+5b3a3+5b2a4+4b+a
⇒      _[3]=5c+8b5a+30b4a2+30b3a3+25b2a4+30b+22a
⇒      _[4]=5d-2b5a-10b4a2-15b3a3-10b2a4-10b-8a
⇒      _[5]=5e-6b5a-20b4a2-15b3a3-15b2a4-15b-9a
⇒ [4]:
⇒      _[1]=a5-1
⇒      _[2]=b-a
⇒      _[3]=c2+3ca+a2
⇒      _[4]=d+c+3a
⇒      _[5]=e-a

```

D.8.6 ntsolve.lib

Library: ntsolve.lib

Purpose: Real Newton Solving of Polynomial Systems

Authors: Wilfred Pohl, email: pohl@mathematik.uni-kl.de
Dietmar Hillebrand

Procedures:

D.8.6.1 nt_solve

Procedure from library `ntsolve.lib` (see [Section D.8.6 \[ntsolve.lib\], page 1865](#)).

Usage: `nt_solve(gls,ini[,ipar]);` `gl`s, `ini`= ideals, `ipar`=list/intvec,
`gl`s: contains the equations, for which a solution will be computed
`ini`: ideal of initial values (approximate solutions to start with),
`ipar`: control integers (default: `ipar = [100, 10]`)
`ipar[1]`: max. number of iterations
`ipar[2]`: accuracy (we have the l_2 -norm $||.||$): accepts solution `sol`
if $||gl(sol)|| < eps0 \cdot (0.1^{ipar[2]})$
where $eps0 = ||gl(ini)||$ is the initial error

Assume: `gl`s is a zerodimensional ideal with `nvars(basing) = size(gls) (>1)`

Return: ideal, coordinates of one solution (if found), 0 else

Note: if `printlevel > 0`: displays comments (default = 0)

Example:

```
LIB "ntsolve.lib";
ring rsq = (real,40),(x,y,z,w),lp;
ideal gls = x2+y2+z2-10, y2+z3+w-8, xy+yz+xz+w5 - 1,w3+y;
ideal ini = 3.1,2.9,1.1,0.5;
intvec ipar = 200,0;
ideal sol = nt_solve(gls,ini,ipar);
sol;
⇒ sol[1]=0.8698104581550055082008024755236550190005
⇒ sol[2]=2.821577445750324600849626251551515976097
⇒ sol[3]=1.132312008466417990006094015504381806805
⇒ sol[4]=-1.413071026406678849397999475515923744295
```

D.8.6.2 triMNewton

Procedure from library `ntsolve.lib` (see [Section D.8.6 \[ntsolve.lib\], page 1865](#)).

Usage: `triMNewton(G,a[,ipar]);` `G`, `a`= ideals, `ipar`=list/intvec

Assume: `G`: g_1, \dots, g_n , a triangular system of n equations in n vars, i.e. $g_i = g_i(\text{var}(n-i+1), \dots, \text{var}(n))$,
`a`: ideal of numbers, coordinates of an approximation of a common zero of `G` to start
with (with `a[i]` to be substituted in `var(i)`),
`ipar`: control integer vector (default: `ipar = [100, 10]`)
`ipar[1]`: max. number of iterations
`ipar[2]`: accuracy (we have as norm $||.||$ absolute value):
accepts solution `sol` if $|G(sol)| < |G(a)| \cdot (0.1^{ipar[2]})$.

Return: an ideal, coordinates of a better approximation of a zero of G

Example:

```
LIB "ntsolve.lib";
ring r = (real,30),(z,y,x),(lp);
ideal i = x^2-1,y^2+x^4-3,z^2-y^4+x-1;
ideal a = 2,3,4;
intvec e = 20,10;
ideal l = trimNewton(i,a,e);
l;
⇒ l[1]==-2.000000000004226573888027914342
⇒ l[2]=1.41421356237309504880168872421
⇒ l[3]=1
```

D.8.7 recover.lib

Library: recover.lib

Purpose: Hybrid numerical/symbolical algorithms for algebraic geometry

Author: Adrian Koch (kocha at rhrk.uni-kl.de)

Overview: In this library you'll find implementations of some of the algorithms presented in the paper listed below: Bertini is used to compute a witness set of a given ideal I . Then a lattice basis reduction algorithm is used to recover exact results from the inexact numerical data. More precisely, we obtain elements of prime components of I , the radical of I , or an elimination ideal of I .

NOTE that Bertini may create quite a lot of files in the current directory (or overwrite files which have the same names as the files it wants to create). It also prints information to the screen.

The usefulness of the results of the exactness recovery algorithms heavily depends on the quality of the witness set and the quality of the lattice basis reduction algorithm. The procedures requiring a witness set as part of their input use a simple, unsophisticated version of the LLL algorithm.

References:

Daniel Bates, Jonathan Hauenstein, Timothy McCoy, Chris Peterson, and Andrew Sommese; Recovering exact results from inexact numerical data in algebraic geometry; Published in Experimental Mathematics 22(1) on pages 38-50 in 2013

Procedures:

D.8.7.1 substAll

Procedure from library `recover.lib` (see [Section D.8.7 \[recover.lib\]](#), page 1866).

Usage: `substAll(v,p);` poly v , list p

Return: poly: the polynomial obtained from v by substituting the elements of p for the ring variables

Note: The list p should have as many elements as there are ring variables.

Example:

```

LIB "recover.lib";
ring r=0,(x,y,z),dp;
poly v=x+y+z;
list p=7/11,5/11,-1/11;
poly f=substAll(v,p);
f;
↪ 1

```

D.8.7.2 veronese

Procedure from library `recover.lib` (see [Section D.8.7 \[recover.lib\], page 1866](#)).

Usage: `veronese(d,p);` int d, list p

Return: ideal: the image of the point p under the degree d Veronese embedding

Note: The list p should have as many elements as there are ring variables. The order of the points in the returned ideal corresponds to the order of the monomials in `maxideal(d)`.

Example:

```

LIB "recover.lib";
ring R=0,(x,y,z),dp;
list p=2,3,5;
ideal V=veronese(1,p);
V;
↪ V[1]=2
↪ V[2]=3
↪ V[3]=5
V=veronese(2,p);
V;
↪ V[1]=25
↪ V[2]=15
↪ V[3]=9
↪ V[4]=10
↪ V[5]=6
↪ V[6]=4

```

See also: [Section 5.1.88 \[maxideal\], page 219](#).

D.8.7.3 getRelations

Procedure from library `recover.lib` (see [Section D.8.7 \[recover.lib\], page 1866](#)).

Usage: `getRelations(p,D,C);` list p, int D, bigint C

Return: list K: a list of ideals; the ideals contain homogeneous polynomial relations of degree $\leq D$ between the components of the point p

Note: This procedure uses only the images of the one point p under the Veronese embeddings to find homogeneous polynomial relations.

Example:

```

LIB "recover.lib";
ring r=(complex,50),(x,y,z),dp;
list p=1,-1,0.5;
getRelations(p,2,10000);
↪ [1]:

```

```

⇒  _[1]=x+y
⇒  _[2]=x-2*z
⇒  [2]:
⇒  _[1]=xz+yz
⇒  _[2]=xy+y2
⇒  _[3]=x2-y2
⇒  _[4]=-xy-xz+yz
⇒  _[5]=-xz+2*z2

```

See also: [Section D.8.7.4 \[getRelationsRadical\]](#), page 1868.

D.8.7.4 getRelationsRadical

Procedure from library `recover.lib` (see [Section D.8.7 \[recover_lib\]](#), page 1866).

Usage: `getRelationsRadical(P,D,C)`; list P, int D, bigint C

Return: list K: a list of ideals; the ideals contain homogeneous polynomial relations of degree $\leq D$ between the components of the points in P

Note: This procedure uses random linear combination of the Veronese embeddings of all points in P to find homogeneous polynomial relations.

Example:

```

LIB "recover.lib";
ring r=(complex,50),(x,y,z),dp;
list p1=1,-1,0.5;
list p2=1,0,-1;
list P=list(p1)+list(p2);
getRelationsRadical(P,2,10**5);
⇒ [1]:
⇒  _[1]=-2*x2+2*y2+yz+2*z2

```

See also: [Section D.8.7.3 \[getRelations\]](#), page 1867.

D.8.7.5 gaussRowWithoutPerm

Procedure from library `recover.lib` (see [Section D.8.7 \[recover_lib\]](#), page 1866).

Usage: `gaussRowWithoutPerm(M)`; M a matrix of constant polynomials

Return: matrix: basic Gaussian row reduction of M, just without permuting the rows

Example:

```

LIB "recover.lib";
ring r=0,x,dp;
matrix M[5][4]=0,0,2,1,4,5,1,3,0,9,2,0,8,1,0,6,0,9,4,1;
print(M);
⇒ 0,0,2,1,
⇒ 4,5,1,3,
⇒ 0,9,2,0,
⇒ 8,1,0,6,
⇒ 0,9,4,1
print(gaussRowWithoutPerm(M));
⇒ 0,0,2,1,
⇒ 4,5,1,3,
⇒ 0,9,2,0,
⇒ 0,0,0,0,
⇒ 0,0,0,0

```

D.8.7.6 gaussColWithoutPerm

Procedure from library `recover.lib` (see [Section D.8.7 \[recover.lib\], page 1866](#)).

Usage: `gaussColWithoutPerm(M)`; M a matrix of constant polynomials

Return: matrix: basic Gaussian column reduction of M, just without permuting the columns

Example:

```
LIB "recover.lib";
ring r=0,x,dp;
matrix M[3][4]=0,1,0,2,1,2,3,4,1,0,5,0;
print(M);
  ↪ 0,1,0,2,
  ↪ 1,2,3,4,
  ↪ 1,0,5,0
print(gaussColWithoutPerm(M));
  ↪ 0,1,0,0,
  ↪ 1,2,0,0,
  ↪ 1,0,2,0
```

D.8.7.7 getWitnessSet

Procedure from library `recover.lib` (see [Section D.8.7 \[recover.lib\], page 1866](#)).

Usage: `getWitnessSet()`;

Assume: There is a text-document "main_data" in the current directory which was produced by Bertini.
The basefield is the field of real numbers or the field of complex numbers.

Return: list; a list P of lists p.i of numbers: P a set of witness points

Note: Reads the file "main_data", searches the strings containing the witness points, and converts them into floating point numbers.

Example:

```
LIB "recover.lib";
//First, we write the input file for bertini, then run bertini
ring r=0,(x,y,z),dp;
ideal I=(x-y)*(y-z)*(x-z);
writeBertiniInput(I,40);
system("sh","bertini input");

```

D.8.7.8 writeBertiniInput

Procedure from library `recover.lib` (see [Section D.8.7 \[recover.lib\]](#), page 1866).

Usage: `writeBertiniInput(J);` ideal J

Return: none; writes the input-file for bertini using the polynomials given by J as functions

Note: Either creates a file named `input` in the current directory or overwrites the existing one.
If you want to pass different parameters to `bertini`, you can edit the produced `input` file or redefine this procedure.

Example:

```
LIB "recover.lib";
ring r=0,(x,y,z),dp;
poly f1=x+y+z;
poly f2=x2+xy+y2;
ideal I=f1,f2;
writeBertiniInput(I,300);
```

D.8.7.9 num_prime_decom

Procedure from library `recover.lib` (see [Section D.8.7 \[recover.lib\]](#), page 1866).

Usage: `num_prime_decom(I,D);` ideal `I`, int `D`
`D` a bound to the degree of the elements of the components of a prime decomposition of `I`.

Return: list of ideals: each of the ideals a prime component of the radical of `I`

Remarks: Uses Bertini.

Note: Should only be called from a ring over the rational numbers.

Example:

```
LIB "recover.lib";
ring R=0,(x,y,z),dp;
ideal I=(x+y)*(y+2z), (x+y)*(x-3z);
int D=2;
int Prec=300;

D.8.7.10 num_prime_decom1

Procedure from library `recover.lib` (see [Section D.8.7 \[recover.lib\]](#), page 1866).

Usage: `num_prime_decom1(P,D,C)`; list P, int D, bigint C
P a list of lists representing a witness point set representing an ideal I D should be a bound to the degree of the elements of the components of the prime decomposition of I
C the number with which the images of the Veronese embeddings are multiplied

Return: list of ideals: each of the ideals a prime component of the radical of I

Note: Should only be called from a ring over the complex numbers.

Example:

```

LIB "recover.lib";
//First, we compute a prime decomposition of the ideal I=x+y;
ring R1=(complex,300,IUnit),(x,y),dp;
list p1=1,-1;
list P=list(p1);
int D=2;
bigint C=bigint(10)**300;
num_prime_decom1(P,D,C);
⇒ [1]:
⇒   _[1]=x+y
//Now, we try to obtain a prime decomposition of the ideal I=(x+y)*(y+2z), (x+y)*(x-3z);
ring R2=(complex,20,IUnit),(x,y,z),dp;

//If you compare the results, you may find that they don't match.
//Most likely, the hybrid algorithm got the second component wrong. This is due to the
//way the algorithm looks for homogeneous polynomial relations, and the specific version
//of the LLL algorithm used here (an implementation into Singular of a rather simple
//version which allows real input). It looks in degree 1, finds one relation and is
//thereafter unable to see a second one. Then it moves on to degree 2 and finds
//relations containing degree-1 relations as a factor.

```

D.8.7.11 num_radical_via_decom

Procedure from library `recover.lib` (see [Section D.8.7 \[recover.lib\]](#), page 1866).

Usage: `num_radical_via_decom(I,D);` ideal `I`, int `D`
 `D` a bound to the degree of the elements of the components.

Return: ideal: the radical of I

Remarks: Uses Bertini.

This procedure merely calls num_prime_decom with the same input and then intersects the returned components.

Note: Should only be called from a ring over the rational numbers.

Example:

```
LIB "recover.lib";
//First, we attempt to compute the radical via the hybrid algorithm.
ring R=0,(x,y,z),dp;
ideal I=(x+y)^2*(y+2z)^3, (x+y)^3*(x-3z)^2;
int D=2;
int Prec=300;
ideal numRad=num_radical_via_decom(I,D,Prec);

D.8.7.12 num_radical_via_randlincom

Procedure from library `recover.lib` (see [Section D.8.7 \[recover_lib\]](#), page 1866).

Usage: `num_radical_via_randlincom(I,D);` ideal I, int D
 D a bound to the degree of the elements of the components.

Return: ideal: the radical of I

Remarks: Uses Bertini.
 Instead of using the images of the Veronese embeddings of each individual witness point, this procedure first computes a random linear combination of those images and searches for homogeneous polynomial relations for this linear combination.

Note: Should only be called from a ring over the rational numbers.

Example:

```

LIB "recover.lib";
//First, we attempt to compute the radical via the hybrid algorithm.
ring R=0,(x,y,z),dp;
ideal I=(x+y)^2*(y+2z)^3, (x+y)^3*(x-3z)^2;
int D=2;
int Prec=300;

D.8.7.15 num_elim

Procedure from library `recover.lib` (see [Section D.8.7 \[recover.lib\]](#), page 1866).

Usage: `num_elim(I,f,D)`; ideal I, poly f, int D
 f the product of the ring variables you want to eliminate D a bound to the degree of
 the elements of the components

Return: ideal: the ideal obtained from I by eliminating the variables specified in f

Remarks: This procedure uses Bertini to compute a set of witness points for I, projects them
 onto the components corresponding to the variables specified in f and then proceeds as
 `num_radical_via_randlincom`.

Note: Should only be called from a ring over the rational numbers.

Example:

```
LIB "recover.lib";
ring r=0,(x,y,z),dp;
poly f1=x-y;
poly f2=z*(x+3y);
poly f3=z*(x2+y2);
ideal I=f1,f2,f3;
//First, we attempt to compute the elimination ideal with the hybrid algorithm.
ideal E1=num_elim(I,z,3,200);

```

D.8.7.16 num_elim1

Procedure from library `recover.lib` (see [Section D.8.7 \[recover.lib\]](#), page 1866).

Usage: `num_elim1(P,D,C,v)`; list P, int D, bigint C, intvec v
P a list of lists representing a witness point set representing an ideal J D should be a bound to the degree of the elements of the components C the number with which the images of the Veronese embeddings are multiplied v an intvec specifying the numbers/positions of the variables to be eliminated

Return: ideal: the ideal obtained from J by eliminating the variables specified in v

Remarks: This procedure just canonically projects the witness points onto the components specified in the intvec v and then applies `num_radical1` to the resulting points.

Note: Should only be called from a ring over the complex numbers.

Example:

```

LIB "recover.lib";
//First, we write the input file for bertini and compute the elimination ideal
//symbolically.
ring r=0,(x,y,z),dp;
poly f1=x-y;
poly f2=z*(x+3y);
poly f3=z*(x2+y2);
ideal J=f1,f2,f3;
ideal E2=elim(J,z);

```

```

writeBertiniInput(J,100);
//Then we attempt to compute the elimination ideal via the hybrid algorithm.
ring R=(complex,100,i),(x,y,z),dp;
system("sh","bertini input");

D.8.7.17 realLLL

Procedure from library `recover.lib` (see [Section D.8.7 \[recover.lib\]](#), page 1866).

Usage: `realLLL(M);` matrix M

Assume: The columns of M represent a basis of a lattice.
The groundfield is the field of real number or the field of complex numbers, the elements of M are real numbers.

Return: matrix: the columns representing an LLL-reduced basis of the lattice given by M

Example:

```

LIB "recover.lib";
ring r=(real,50),x,dp;
matrix M[5][4]=
1,0,0,0,
0,1,0,0,
0,0,1,0,
0,0,0,1,
5*81726716.91827716, 817267.1691827716, poly(10)**30, 13*81726716.91827716;

```

D.8.8 rootisolation.lib

Library: `rootisolation.lib`

Purpose: implements an algorithm for real root isolation using interval arithmetic

Authors: Dominik Bendle (bendle@rhrk.uni-kl.de)
Janko Boehm (boehm@mathematik.uni-lk.de), supervisor Fachpraktikum
Clara Petroll (petroll@rhrk.uni-kl.de)

Overview: In this library the interval arithmetic from `interval.so` is used. The new type `ivmat`, a matrix consisting of intervals, is implemented as `newstruct`. There are various functions for computations with interval matrices implemented, such as Gaussian elimination for interval matrices.

Interval arithmetic, the interval Newton Step and exclusion methods are used to implement the procedure `rootIsolation`, an algorithm which finds boxes containing elements of the vanishing locus of an ideal. This algorithm is specialised for zero-dimensional radical ideals. The theory about the interval Newton Step is detailed in [2].

Note that interval arithmetic and the aforementioned procedures are intended for rational or real polynomial rings.

```

Procedures: See also: [Section D.8.2 \[interval_lib\]](#), page 1829.

D.8.8.1 bounds

Procedure from library `rootisolation.lib` (see [Section D.8.8 \[rootisolation_lib\]](#), page 1894).

Usage: `bounds(a); a number;`
 `bounds(a, b); a, b number;`

Return: interval: if `size(#)==0` it returns the interval `[a, a]`, else the interval `[a,#[1]]`

Example:

```
LIB "rootisolation.lib";
ring R = 0,x,dp;
interval I = bounds(1);
I;
↪ [1, 1]
interval J = bounds(2/3,3);
J;
↪ [2/3, 3]
```

D.8.8.2 length

Procedure from library `rootisolation.lib` (see [Section D.8.8 \[rootisolation_lib\]](#), page 1894).

Usage: `length(I); I interval`

Return: number, the Euclidean length of the interval

Example:

```

LIB "rootisolation.lib";
ring R = 0,x,dp;
interval I = -1,3;
length(I);
↪ 4
I = 1/5,1/3;
length(I);
↪ 2/15

```

D.8.8.3 boxSet

Procedure from library `rootisolation.lib` (see [Section D.8.8 \[rootisolation.lib\], page 1894](#)).

Usage: `boxSet(B, i, I);` B box, i int, I interval

Return: new box C where $C[i] = I$

Purpose: modifies a single entry of a box

Example:

```

LIB "rootisolation.lib";
ring R = 0,(x,y,z),dp;
box B; B;
↪ [0, 0] x [0, 0] x [0, 0]
B = boxSet(B, 2, bounds(-1,1)); B;
↪ [0, 0] x [-1, 1] x [0, 0]
B = boxSet(B, 1, B[2]); B;
↪ [-1, 1] x [-1, 1] x [0, 0]

```

D.8.8.4 ivmatInit

Procedure from library `rootisolation.lib` (see [Section D.8.8 \[rootisolation.lib\], page 1894](#)).

Usage: `ivmatInit(m, n);` m, n int

Return: mxn matrix of $[0,0]$ -intervals

Purpose: initialises an interval matrix with $[0,0]$ intervals to ensure the proper structure of the `ivmat` type

Example:

```

LIB "rootisolation.lib";
ring R = 0,x(1..5),dp;
ivmat A = ivmatInit(4, 5); A;
↪ [0, 0],[0, 0],[0, 0],[0, 0],[0, 0]
↪ [0, 0],[0, 0],[0, 0],[0, 0],[0, 0]
↪ [0, 0],[0, 0],[0, 0],[0, 0],[0, 0]
↪ [0, 0],[0, 0],[0, 0],[0, 0],[0, 0]
↪

```

D.8.8.5 ivmatSet

Procedure from library `rootisolation.lib` (see [Section D.8.8 \[rootisolation.lib\], page 1894](#)).

Usage: `ivmatSet(A, i, j, I);` A ivmat, i, j, int, I interval

Return: interval matrix A where $A[i][j] == I$

Purpose: modify a single entry of an `ivmat`

Example:

```
LIB "rootisolation.lib";
ring R = 0,x,dp;
ivmat A = ivmatInit(2,2);          A;
↪ [0, 0],[0, 0]
↪ [0, 0],[0, 0]
↪
A = ivmatSet(A, 1, 2, bounds(1, 2)); A;
↪ [0, 0],[1, 2]
↪ [0, 0],[0, 0]
↪
```

D.8.8.6 unitMatrix

Procedure from library `rootisolation.lib` (see [Section D.8.8 \[rootisolation.lib\]](#), page 1894).

Usage: `unitMatrix(n); n int`

Return: $n \times n$ unit interval matrix

Example:

```
LIB "rootisolation.lib";
ring R = 0,(x,y),dp;
unitMatrix(2);
↪ [1, 1],[0, 0]
↪ [0, 0],[1, 1]
↪
unitMatrix(3);
↪ [1, 1],[0, 0],[0, 0]
↪ [0, 0],[1, 1],[0, 0]
↪ [0, 0],[0, 0],[1, 1]
↪
```

D.8.8.7 ivmatGaussian

Procedure from library `rootisolation.lib` (see [Section D.8.8 \[rootisolation.lib\]](#), page 1894).

Usage: `ivmatGaussian(A); A ivmat`

Return: 0, if A not invertible, $(1, A_{\text{inv}})$ if A invertible where A_{inv} is the inverse matrix

Purpose: Inverts an interval matrix using Gaussian elimination in the setting of interval arithmetic. Pivoting is handled as a special case as $I/I \neq [1,1]$ and $I-I \neq [0,0]$ in general.

Example:

```
LIB "rootisolation.lib";
ring R = 0,(x,y),dp;
ideal I = 2x2-xy+2y2-2,2x2-3xy+3y2-2;
box B = list(bounds(7/8, 9/8), bounds(-1/10, 1/20));
ivmat J = evalJacobianAtBox (I, B); J;
↪ [69/20, 23/5],[-61/40, -27/40]
↪ [67/20, 24/5],[-159/40, -93/40]
```

```

↳
list result = ivmatGaussian(J);
ivmat Jinv = result[2];
Jinv;
↳ [1060/4273, 620/187], [-1220/561, -180/4273]
↳ [2680/12819, 1280/187], [-920/187, -3680/12819]
↳
Jinv * J;
↳ [-7657037/799051, 12073835/799051], [-3961862/799051, 6773506/799051]
↳ [-18293234/799051, 73172936/2397153], [-7807572/799051, 15513600/799051]
↳

```

D.8.8.8 evalPolyAtBox

Procedure from library `rootisolation.lib` (see [Section D.8.8 \[rootisolation.lib\]](#), page 1894).

Usage: `evalPolyAtBox(f, B);` *f* poly, *B* box

Return: interval, evaluation of *f* at *B* using interval arithmetic

Purpose: computes an interval extension of the polynomial

Example:

```

LIB "rootisolation.lib";
ring R = 0,(x,y),dp;
poly f = x2+y-1;
box B = list(bounds(-1,1), bounds(1,3)/2);
interval I = evalPolyAtBox(f, B); I;
↳ [-1/2, 3/2]

```

D.8.8.9 evalJacobianAtBox

Procedure from library `rootisolation.lib` (see [Section D.8.8 \[rootisolation.lib\]](#), page 1894).

Usage: `evalJacobianAtBox(I, B);` *I* ideal, *B* box

Return: Jacobian matrix of *I* where polynomials are evaluated at *B*

Purpose: evaluates each polynomial of the Jacobian matrix of *I* using interval arithmetic

Example:

```

LIB "rootisolation.lib";
ring R = 0,(x,y),dp;
ideal I = 2x2-xy+2y2-2, 2x2-3xy+3y2-2;
interval J = bounds(-1,1);
evalJacobianAtBox(I, list(J,J));
↳ [-5, 5], [-5, 5]
↳ [-7, 7], [-9, 9]
↳

```

D.8.8.10 rootIsolationNoPreprocessing

Procedure from library `rootisolation.lib` (see [Section D.8.8 \[rootisolation.lib\]](#), page 1894).

Usage: `rootIsolationNoPreprocessing(I, B, eps);` *I* ideal, *B* list of boxes, *eps* number;

Assume: *I* is a zero-dimensional radical ideal

- Return:** (L1, L2), where L1 contains boxes smaller than ϵ which may contain an element of $V(I)$, i.e. a root and L2 contains boxes which contain exactly one element of $V(I)$
- Purpose:** Given input box(es) **start** we try to find all roots of I lying in **start** by computing boxes that contain exactly one root. If $\epsilon > 0$ then boxes that become smaller than ϵ will be returned.
- Theory:** We first check for every box if it contains no roots by interval arithmetic. If this is inconclusive we apply the Newton step which, as outlined in [2] and [3], converges to a root lying in the starting box. If the result of the Newton step is already contained in the interior of the starting box, it contains a unique root.
- Note:** While `rootIsolation` does, `rootIsolationNoPreprocessing` does not check input ideal for necessary conditions.

Example:

```
LIB "rootisolation.lib";
ring R = 0,(x,y),dp;
ideal I = 2x2-xy+2y2-2,2x2-3xy+3y2-2; // V(I) has four elements
interval i = bounds(-3/2,3/2);
box B = list(i, i);
list result = rootIsolationNoPreprocessing(I, list(B), 1/512);
size(result[1]);
⇒ 0
size(result[2]);
⇒ 4
result;
⇒ [1]:
⇒ empty list
⇒ [2]:
⇒ [1]:
⇒ [-9/16, -15/32] x [-129/128, -127/128]
⇒ [2]:
⇒ [15/32, 33/64] x [31/32, 129/128]
⇒ [3]:
⇒ [63/64, 33/32] x [-1/256, 1/32]
⇒ [4]:
⇒ [-129/128, -63/64] x [-1/256, 1/32]
```

D.8.8.11 rootIsolation

Procedure from library `rootisolation.lib` (see [Section D.8.8 \[rootisolation.lib\]](#), page 1894).

- Usage:** `rootIsolation(I, [start, eps]);` I ideal, start box, ϵ number
- Assume:** I is a zero-dimensional radical ideal
- Return:** (L1, L2), where L1 contains boxes smaller than ϵ which may contain an element of $V(I)$, i.e. a root and L2 contains boxes which contain exactly one element of $V(I)$
- Purpose:** same as `rootIsolationNoPreprocessing`, but speeds up computation by preprocessing starting box
- Theory:** As every root of I is a root of the polynomials $I[i]$, we use Groebner elimination to find univariate polynomials for every variable which have these roots as well. Using that I is zero-dimensional these Groebner bases may be quickly computed using FGLM. Applying root isolation to these univariate polynomials then provides smaller starting boxes which speed up computations in the multivariate case.

Note: This algorithm and some procedures used therein perform Groebner basis computations in **basing**. It is thus advised to define I w.r.t. a fast monomial ordering. The algorithm performs checks on I to prevent errors. If I does not have the right number of generators, we first try to find a suitable Groebner basis. If this fails we apply the algorithm to the triangular decomposition of I .

Example:

```
LIB "rootisolation.lib";
ring R = 0,(x,y),dp;
ideal I = 2x2-xy+2y2-2,2x2-3xy+3y2-2; // V(I) has four elements
interval i = bounds(-3/2,3/2);
box B = list(i, i);
list result = rootIsolation(I, B);
result;
⇒ [1]:
⇒ empty list
⇒ [2]:
⇒ [1]:
⇒ [-1, -1] x [0, 0]
⇒ [2]:
⇒ [-1/2, -1/2] x [-1, -1]
⇒ [3]:
⇒ [1/2, 1/2] x [1, 1]
⇒ [4]:
⇒ [1, 1] x [0, 0]
```

D.8.8.12 rootIsolationPrimdec

Procedure from library `rootisolation.lib` (see [Section D.8.8 \[rootisolation.lib\]](#), page 1894).

Usage: `rootIsolationPrimdec(I); I ideal`

Assume: I is a zero-dimensional radical ideal

Return: L , where L contains boxes which contain exactly one element of $V(I)$

Purpose: same as `rootIsolation`, but speeds up computation and improves output by doing a primary decomposition before doing the root isolation

Theory: For the primary decomposition we use the algorithm of Gianni-Traeger-Zarcharias.

Note: This algorithm and some procedures used therein perform Groebner basis computations in **basing**. It is thus advised to define I w.r.t. a fast monomial ordering.

Example:

```
LIB "rootisolation.lib";
ring R = 0,(x,y),dp;
ideal I = 2x2-xy+2y2-2,2x2-3xy+3y2-2; // V(I) has four elements
list result = rootIsolationPrimdec(I);
result;
⇒ [1]:
⇒ [1, 1] x [0, 0]
⇒ [2]:
⇒ [1/2, 1/2] x [1, 1]
⇒ [3]:
```

```

⇒      [-1/2, -1/2] x [-1, -1]
⇒ [4]:
⇒      [-1, -1] x [0, 0]

```

D.8.9 signcond_lib

Library: signcond.lib

Purpose: Routines for computing realizable sign conditions

Author: Enrique A. Tobis, etobis@dc.uba.ar

Overview: Routines to determine the number of solutions of a multivariate polynomial system which satisfy a given sign configuration.

References:

Basu, Pollack, Roy, "Algorithms in Real Algebraic Geometry", Springer, 2003.

Procedures:

D.8.9.1 signcnd

Procedure from library `signcond.lib` (see [Section D.8.9 \[signcond_lib\]](#), page 1901).

Usage: signcnd(P,I); ideal P,I

Return: list: the sign conditions realized by the polynomials of P on V(I). The output of signcnd is a list of two lists. Both lists have the same length. This length is the number of sign conditions realized by the polynomials of P on the set V(i).
Each element of the first list indicates a sign condition of the polynomials of P.
Each element of the second list indicates how many elements of V(I) give rise to the sign condition expressed by the same position on the first list.
See the example for further explanations of the output.

Assume: I is a Groebner basis.

Note: The procedure psigncnd performs some pretty printing of this output.

Example:

```

LIB "signcond.lib";
ring r = 0,(x,y),dp;
ideal i = (x-2)*(x+3)*x,y*(y-1);
ideal P = x,y;
list l = signcnd(P,i);
size(l[1]);      // = the number of sign conditions of P on V(i)
⇒ 6
//Each element of l[1] indicates a sign condition of the polynomials of P.
//The following means P[1] > 0, P[2] = 0:
l[1][2];
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 0
//Each element of l[2] indicates how many elements of V(I) give rise to
//the sign condition expressed by the same position on the first list.
//The following means that exactly 1 element of V(I) gives rise to the
//condition P[1] > 0, P[2] = 0:

```

```
l[2][2];
 $\mapsto$  1
```

See also: [Section D.8.9.3 \[firstoct\]](#), page 1902; [Section D.8.9.2 \[psigncnd\]](#), page 1902.

D.8.9.2 psigncnd

Procedure from library `signcond.lib` (see [Section D.8.9 \[signcond.lib\]](#), page 1901).

Usage: `psigncnd(P,l)`; ideal P, list l

Return: list: a formatted version of l

Example:

```
LIB "signcond.lib";
ring r = 0,(x,y),dp;
ideal i = (x-2)*(x+3)*x,(y-1)*(y+2)*(y+4);
ideal P = x,y;
list l = signcnd(P,i);
psigncnd(P,l);
 $\mapsto$  1 elements of V(I) satisfy {P[1] = 0,P[2] > 0}
 $\mapsto$  1 elements of V(I) satisfy {P[1] > 0,P[2] > 0}
 $\mapsto$  1 elements of V(I) satisfy {P[1] < 0,P[2] > 0}
 $\mapsto$  2 elements of V(I) satisfy {P[1] = 0,P[2] < 0}
 $\mapsto$  2 elements of V(I) satisfy {P[1] > 0,P[2] < 0}
 $\mapsto$  2 elements of V(I) satisfy {P[1] < 0,P[2] < 0}
 $\mapsto$ 
```

See also: [Section D.8.9.1 \[signcnd\]](#), page 1901.

D.8.9.3 firstoct

Procedure from library `signcond.lib` (see [Section D.8.9 \[signcond.lib\]](#), page 1901).

Usage: `firstoct(I)`; I ideal

Return: number: the number of points of V(I) lying in the first octant

Assume: I is given by a Groebner basis.

Example:

```
LIB "signcond.lib";
ring r = 0,(x,y),dp;
ideal i = (x-2)*(x+3)*x,y*(y-1);
firstoct(i);
 $\mapsto$  1
```

See also: [Section D.8.9.1 \[signcnd\]](#), page 1901.

D.8.10 zeroset_lib

Library: `zeroset.lib`

Purpose: Procedures for roots and factorization

Author: Thomas Bayer, email: tbayer@mathematik.uni-kl.de,
<http://wwwmayr.informatik.tu-muenchen.de/personen/bayert/>
 Current address: Hochschule Ravensburg-Weingarten

Overview: Algorithms for finding the zero-set of a zero-dim. ideal in $\mathbb{Q}(a)[x_1, \dots, x_n]$, roots and factorization of univariate polynomials over $\mathbb{Q}(a)[t]$ where a is an algebraic number. Written in the scope of the diploma thesis (advisor: Prof. Gert-Martin Greuel) 'Computations of moduli spaces of semiquasihomogeneous singularities and an implementation in Singular'. This library is meant as a preliminary extension of the functionality of Singular for univariate factorization of polynomials over simple algebraic extensions in characteristic 0.

Note: Subprocedures with postfix 'Main' require that the ring contains a variable 'a' and no parameters, and the ideal 'mpoly', where 'minpoly' from the basering is stored.

Procedures:

D.8.10.1 Quotient

Procedure from library `zeroset.lib` (see [Section D.8.10 \[zeroset.lib\]](#), page 1902).

Usage: `Quotient(f, g);` where f, g are polynomials

Purpose: compute the quotient q and remainder r s.t. $f = g \cdot q + r$, $\deg(r) < \deg(g)$

Return: list of polynomials
`_[1]` = quotient q
`_[2]` = remainder r

Assume: `basing = Q[x]` or `Q(a)[x]`

Note: This procedure is outdated, and should no longer be used. Use `div` and `mod` instead.

Example:

```
LIB "zeroset.lib";
ring R = (0,a), x, lp;
minpoly = a2+1;
poly f = x4 - 2;
poly g = x - a;
list qr = Quotient(f, g);
qr;
⇒ [1]:
⇒ x3+(a)*x2-x+(-a)
⇒ [2]:
⇒ 0
qr[1]*g + qr[2] - f;
⇒ 1
```

D.8.10.2 remainder

Procedure from library `zeroset.lib` (see [Section D.8.10 \[zeroset.lib\]](#), page 1902).

Usage: `remainder(f, g);` where f, g are polynomials

Purpose: compute the remainder of the division of f by g , i.e. a polynomial r s.t. $f = g \cdot q + r$, $\deg(r) < \deg(g)$.

Return: `poly`

Assume: `basing = Q[x]` or `Q(a)[x]`

Note: outdated, use `mod/reduce` instead

Example:

```
LIB "zeroset.lib";
ring R = (0,a), x, lp;
minpoly = a2+1;
poly f = x4 - 1;
poly g = x3 - 1;
remainder(f, g);
↳ x-1
```

D.8.10.3 roots

Procedure from library `zeroset.lib` (see [Section D.8.10 \[zeroset.lib\]](#), page 1902).

Usage: `roots(f)`; where `f` is a polynomial

Purpose: compute all roots of `f` in a finite extension of $\mathbb{Q}\mathbb{Q}$ without multiplicities.

Return: ring, a polynomial ring over an extension field of $\mathbb{Q}\mathbb{Q}$, containing a list `'theRoots'` and polynomials `'newA'` and `'f'`:

- `'theRoots'` is the list of roots of the polynomial `f` (no multiplicities)
- if the ground field is $\mathbb{Q}(a')$ and the extension field is $\mathbb{Q}(a)$, then `'newA'` is the representation of `a'` in $\mathbb{Q}(a)$.
If the basering contains a parameter `'a'` and the minpoly remains unchanged then `'newA' = 'a'`.
- If the basering does not contain a parameter then `'newA' = 'a'` (default).
- `'f'` is the polynomial `f` in $\mathbb{Q}(a)$ (`a'` being substituted by `'newA'`)

Assume: ground field to be \mathbb{Q} or a simple extension of \mathbb{Q} given by a minpoly

Example:

```
LIB "zeroset.lib";
ring R = (0,a), x, lp;
minpoly = a2+1;
poly f = x3 - a;
def R1 = roots(f);
↳
↳ // 'roots' created a new ring which contains the list 'theRoots' and
↳ // the polynomials 'f' and 'newA'
↳ // To access the roots, newA and the new representation of f, type
↳   def R = roots(f); setring R; theRoots; newA; f;
↳
↳ setring R1;
↳ minpoly;
↳ (a4-a2+1)
↳ newA;
↳ (a3)
↳ f;
↳ x3+(-a3)
↳ theRoots;
↳ [1]:
↳   (-a3)
↳ [2]:
↳   (a)
```

```

↳ [3]:
↳      (a3-a)
map F;
F[1] = theRoots[1];
F(f);
↳ 0

```

D.8.10.4 sqfrNorm

Procedure from library `zeroset.lib` (see [Section D.8.10 \[zeroset.lib\]](#), page 1902).

Usage: `sqfrNorm(f)`; where f is a polynomial in $\mathbb{Q}(a)[x]$

Purpose: compute the norm of the squarefree polynomial f in $\mathbb{Q}(a)[x]$.

Return: list with 3 entries

```

_ [1] = squarefree norm of g (poly)
_ [2] = g (= f(x - s*a)) (poly)
_ [3] = s (int)

```

Assume: f must be squarefree, $\text{basing} = \mathbb{Q}(a)[x]$ and $\text{minpoly} \neq 0$.

Note: the norm is an element of $\mathbb{Q}[x]$

Example:

```

LIB "zeroset.lib";
ring R = (0,a), x, lp;
minpoly = a2+1;
poly f = x4 - 2*x + 1;
sqfrNorm(f);
↳ [1]:
↳      x8+4*x6-4*x5+8*x4+8*x3-4*x2+8*x+8
↳ [2]:
↳      x4+(-4a)*x3-6*x2+(4a-2)*x+(2a+2)
↳ [3]:
↳      1

```

D.8.10.5 zeroSet

Procedure from library `zeroset.lib` (see [Section D.8.10 \[zeroset.lib\]](#), page 1902).

Usage: `zeroSet(I [,opt])`; I =ideal, opt =integer

Purpose: compute the zero-set of the zero-dim. ideal I , in a finite extension of $\mathbb{Q}\mathbb{Q}$.

Return: ring, a polynomial ring over an extension field of $\mathbb{Q}\mathbb{Q}$, containing a list 'theZeroset', a polynomial 'newA', and an ideal 'id':

- 'theZeroset' is the list of the zeros of the ideal I , each zero is an ideal.
- if the ground field is $\mathbb{Q}(b)$ and the extension field is $\mathbb{Q}(a)$, then 'newA' is the representation of b in $\mathbb{Q}(a)$.
If the basering contains a parameter 'a' and the minpoly remains unchanged then 'newA' = 'a'.
- If the basering does not contain a parameter then 'newA' = 'a' (default).
- 'id' is the ideal I in $\mathbb{Q}(a)[x_1, \dots]$ (a' substituted by 'newA')

- Assume:** $\dim(I) = 0$, and ground field to be \mathbb{Q} or a simple extension of \mathbb{Q} given by a minpoly.
- Options:** $\text{opt} = 0$: no primary decomposition (default)
 $\text{opt} > 0$: primary decomposition
- Note:** If I contains an algebraic number (parameter) then I must be transformed w.r.t. 'newA' in the new ring.

Example:

```
LIB "zeroset.lib";
ring R = (0,a), (x,y,z), lp;
minpoly = a2 + 1;
ideal I = x2 - 1/2, a*z - 1, y - 2;
def T = zeroSet(I);
setring T;
minpoly;
↪ (4a4+4a2+9)
newA;
↪ (1/3a3+5/6a)
id;
↪ id[1]=(1/3a3+5/6a)*z-1
↪ id[2]=y-2
↪ id[3]=2*x2-1
theZeroset;
↪ [1]:
↪   _[1]=(-1/3a3+1/6a)
↪   _[2]=2
↪   _[3]=(-1/3a3-5/6a)
↪ [2]:
↪   _[1]=(1/3a3-1/6a)
↪   _[2]=2
↪   _[3]=(-1/3a3-5/6a)
map F1 = basering, theZeroset[1];
map F2 = basering, theZeroset[2];
F1(id);
↪ _[1]=0
↪ _[2]=0
↪ _[3]=0
F2(id);
↪ _[1]=0
↪ _[2]=0
↪ _[3]=0
```

D.8.10.6 egcdMain

Procedure from library `zeroset.lib` (see [Section D.8.10 \[zeroset.lib\]](#), page 1902).

- Usage:** `egcdMain(f, g)`; where f, g are polynomials in $\mathbb{Q}[a, x]$
- Purpose:** compute the polynomial gcd of f and g over $\mathbb{Q}(a)[x]$
- Return:** poly
- Assume:** `basering = $\mathbb{Q}[x, a]$` and ideal `mpoly` is defined (it might be 0), this represents the ring $\mathbb{Q}(a)[x]$ together with its minimal polynomial.
- Note:** outdated, use `gcd` instead

D.8.10.7 factorMain

Procedure from library `zeroset.lib` (see [Section D.8.10 \[zeroset.lib\], page 1902](#)).

Usage: `factorMain(f)`; where f is a polynomial

Purpose: compute the factorization of the squarefree polynomial f over $\mathbb{Q}(a)[t]$, $\text{minpoly} = p(a)$.

Return: list with 2 entries
 $_ [1]$ = factors, first is a constant
 $_ [2]$ = multiplicities (not yet implemented)

Assume: $\text{basing} = \mathbb{Q}[x,a]$, representing $\mathbb{Q}(a)[x]$. An ideal mpoly must be defined, representing the minimal polynomial (it might be 0!).

Note: outdated, use `factorize` instead

D.8.10.8 invertNumberMain

Procedure from library `zeroset.lib` (see [Section D.8.10 \[zeroset.lib\], page 1902](#)).

Usage: `invertNumberMain(f)`; where f is a polynomial in $\mathbb{Q}[a]$

Purpose: compute $1/f$ if f is a number in $\mathbb{Q}(a)$, i.e., f is represented by a polynomial in $\mathbb{Q}[a]$.

Return: poly $1/f$

Assume: $\text{basing} = \mathbb{Q}[x_1, \dots, x_n, a]$, ideal mpoly must be defined and $\neq 0$!

Note: outdated, use `/` instead

D.8.10.9 quotientMain

Procedure from library `zeroset.lib` (see [Section D.8.10 \[zeroset.lib\], page 1902](#)).

Usage: `quotientMain(f, g)`; where f, g are polynomials in $\mathbb{Q}(a)[x]$

Purpose: compute the quotient q and remainder r s.th. $f = g \cdot q + r$, $\deg(r) < \deg(g)$

Return: list of polynomials
 $_ [1]$ = quotient q
 $_ [2]$ = remainder r

Assume: $\text{basing} = \mathbb{Q}[x,a]$ and ideal mpoly is defined (it might be 0), this represents the ring $\mathbb{Q}(a)[x]$ together with its minimal polynomial.

Note: outdated, use `div/mod` instead

D.8.10.10 remainderMain

Procedure from library `zeroset.lib` (see [Section D.8.10 \[zeroset.lib\], page 1902](#)).

Usage: `remainderMain(f, g)`; where f, g are polynomials in $\mathbb{Q}[a,x]$

Purpose: compute the remainder r s.t. $f = g \cdot q + r$, $\deg(r) < \deg(g)$

Return: poly

Assume: $\text{basing} = \mathbb{Q}[x,a]$ and ideal mpoly is defined (it might be 0), this represents the ring $\mathbb{Q}(a)[x]$ together with its minimal polynomial.

Note: outdated, use `mod/reduce` instead

D.8.10.11 rootsMain

Procedure from library `zeroset.lib` (see [Section D.8.10 \[zeroset.lib\], page 1902](#)).

- Usage:** `rootsMain(f)`; where f is a polynomial in $\mathbb{Q}[a, x]$
- Purpose:** compute all roots of f in a finite extension of the $\mathbb{Q}\mathbb{Q}$ without multiplicities.
- Return:** list, all entries are polynomials
 `_[1]` = roots of f , each entry is a polynomial
 `_[2]` = 'newA' - if the ground field is $\mathbb{Q}(b)$ and the extension field is $\mathbb{Q}(a)$, then 'newA' is the representation of b in $\mathbb{Q}(a)$
 `_[3]` = minpoly of the algebraic extension of the ground field
- Assume:** `basing = $\mathbb{Q}[x, a]$` ideal mpoly must be defined, it might be 0!
- Note:** might change the ideal mpoly!!

D.8.10.12 sqfrNormMain

Procedure from library `zeroset.lib` (see [Section D.8.10 \[zeroset.lib\], page 1902](#)).

- Usage:** `sqfrNorm(f)`; where f is a polynomial in $\mathbb{Q}(a)[x]$
- Purpose:** compute the norm of the squarefree polynomial f in $\mathbb{Q}(a)[x]$.
- Return:** list with 3 entries
 `_[1]` = squarefree norm of g (poly)
 `_[2]` = g ($= f(x - s \cdot a)$) (poly)
 `_[3]` = s (int)
- Assume:** f must be squarefree, `basing = $\mathbb{Q}[x, a]$` and ideal mpoly is equal to 'minpoly', this represents the ring $\mathbb{Q}(a)[x]$ together with 'minpoly'.
- Note:** the norm is an element of $\mathbb{Q}[x]$

D.8.10.13 containedQ

Procedure from library `zeroset.lib` (see [Section D.8.10 \[zeroset.lib\], page 1902](#)).

- Usage:** `containedQ(data, f [, opt])`; `data=list`; `f=any type`; `opt=integer`
- Purpose:** test if f is an element of `data`.
- Return:** int
 0 if f not contained in `data`
 1 if f contained in `data`
- Options:** `opt = 0` : use '==' for comparing f with elements from `data`
 `opt = 1` : use `sameQ` for comparing f with elements from `data`

D.8.10.14 sameQ

Procedure from library `zeroset.lib` (see [Section D.8.10 \[zeroset.lib\], page 1902](#)).

- Usage:** `sameQ(a, b)`; `a, b=list/intvec`
- Purpose:** test `a == b` elementwise, i.e., `a[i] = b[i]`.
- Return:** int
 0 if `a != b`
 1 if `a == b`

D.9 Visualization

D.9.1 graphics_lib

Library: graphics.lib

Purpose: Procedures to use Graphics with Mathematica

Author: Christian Gorzel, gorzelc@math.uni-muenster.de

Procedures:

D.9.1.1 staircase

Procedure from library `graphics.lib` (see [Section D.9.1 \[graphics_lib\]](#), page 1909).

Usage: `staircase(s,I)`; `s` a string, `I` ideal in two variables

Return: string with Mathematica input for displaying staircase diagrams of an ideal `I`, i.e. exponent vectors of the initial ideal of `I`

Note: ideal `I` should be given by a standard basis. Let `s=""` and copy and paste the result into a Mathematica notebook.

Example:

```
LIB "graphics.lib";
ring r0 = 0,(x,y),ls;
ideal I = -1x2y6-1x4y2, 7x6y5+1/2x7y4+6x4y6;
staircase("",std(I));
⇒
⇒ Show[Graphics[{
⇒ {GrayLevel[0.5],Map[Rectangle[#{9,9]} &, {{2,6},{6,2}}]},
⇒ {PointSize[0.03], Map[Point,{{2,6},{6,2}}]},
⇒ Table[Circle[{i,j},0.1],{i,0,9},{j,0,9}]},
⇒ Axes->True,AspectRatio->Automatic]]
⇒
ring r1 = 0,(x,y),dp;
ideal I = fetch(r0,I);
staircase("",std(I));
⇒
⇒ Show[Graphics[{
⇒ {GrayLevel[0.5],Map[Rectangle[#{12,9]} &, {{2,6},{7,4},{9,2}}]},
⇒ {PointSize[0.03], Map[Point,{{2,6},{7,4},{9,2}}]},
⇒ Table[Circle[{i,j},0.1],{i,0,12},{j,0,9}]},
⇒ Axes->True,AspectRatio->Automatic]]
⇒
ring r2 = 0,(x,y),wp(2,3);
ideal I = fetch(r0,I);
staircase("",std(I));
⇒
⇒ Show[Graphics[{
⇒ {GrayLevel[0.5],Map[Rectangle[#{13,9]} &, {{2,6},{8,3},{10,2},{6,5}}]},
⇒ {PointSize[0.03], Map[Point,{{2,6},{8,3},{10,2},{6,5}}]},
⇒ Table[Circle[{i,j},0.1],{i,0,13},{j,0,9}]},
⇒ Axes->True,AspectRatio->Automatic]]
```

```

↳
// Paste the output into a Mathematica notebook
// active evaluation of the cell with SHIFT RETURN

```

D.9.1.2 mathinit

Procedure from library `graphics.lib` (see [Section D.9.1 \[graphics.lib\], page 1909](#)).

Usage: `mathinit();`

Return: initializing string for loading Mathematica's `ImplicitPlot`

Example:

```

LIB "graphics.lib";
mathinit();
↳ << Graphics`ImplicitPlot`
// Paste the output into a Mathematica notebook
// active evaluation of the cell with SHIFT RETURN

```

D.9.1.3 mplot

Procedure from library `graphics.lib` (see [Section D.9.1 \[graphics.lib\], page 1909](#)).

Usage: `mplot(fname, I [,I1,I2,..,s]);` `fname=string;` `I,I1,I2,..=ideals,` `s=string` representing the plot region.

Use the ideals `I1,I2,..` in order to produce multiple plots (they need to have the same number of entries as `I!`).

Return: string, text with Mathematica commands to display a plot

Note: The `plotregion` is defaulted to `-1,1` around zero.

For implicit given curves enter first the string returned by procedure `mathinit` into Mathematica in order to load `ImplicitPlot`. The following conventions for `I` are used:

- ideal with 2 entries in one variable means a parametrised plane curve,
- ideal with 3 entries in one variable means a parametrised space curve,
- ideal with 3 entries in two variables means a parametrised surface,
- ideal with 2 entries in two variables means an implicit curve given as `I[1]==I[2]`,
- ideal with 1 entry (or one polynomial) in two variables means an implicit curve given as `f == 0`,

Example:

```

LIB "graphics.lib";
// ----- plane curves -----
ring rr0 = 0,x,dp; export rr0;
ideal I = x3 + x, x2;
ideal J = x2, -x+x3;
mplot("",I,J,"-2,2");
↳
↳ ParametricPlot[{{s^3+s,s^2},{s^2,s^3-s}},{s,-2,2},
↳ AspectRatio->Automatic];
↳
// Paste the output into a Mathematica notebook
// active evaluation of the cell with SHIFT RETURN
// ----- space curves -----

```

```

I = x3,-1/10x3+x2,x2;
mplot("",I);
⇒
⇒ ParametricPlot3D[{{s^3,-1/10*s^3+s^2,s^2}},{s,-1,1},
⇒ ViewPoint->{1.3,-2.4,2}];
⇒
// Paste the output into a Mathematica notebook
// active evaluation of the cell with SHIFT RETURN
// ----- surfaces -----
ring rr1 = 0,(x,y),dp; export rr1;
ideal J = xy,y,x2;
mplot("",J,"-2,1","1,2");
⇒
⇒ ParametricPlot3D[{{s*t,t,s^2}},{s,-2,1},{t,1,2},
⇒ Boxed->True, Axes->True, ViewPoint->{1.3,-2.4,2}];
⇒
// Paste the output into a Mathematica notebook
// active evaluation of the cell with SHIFT RETURN
kill rr0,rr1;

```

D.9.2 latex_lib

Library: latex.lib

Purpose: Typesetting of Singular-Objects in LaTeX2e

Author: Christian Gorzel, gorzelc@math.uni-muenster.de

Global variables:

TeXwidth, TeXnofrac, TeXbrack, TeXproj, TeXaligned, TeXreplace, NoDollars are used to control the typesetting. Call `texdemo()`; to obtain a LaTeX2e file `texlibdemo.tex` explaining the features of `latex.lib` and its global variables.

`TeXwidth` (int) -1, 0, 1..9, >9: controls breaking of long polynomials

`TeXnofrac` (int) flag: write $1/2$ instead of $\frac{1}{2}$

`TeXbrack` (string) "{", "(", "<", "|", empty string:

controls brackets around ideals and matrices

`TeXproj` (int) flag: write ":" instead of "," in vectors

`TeXaligned` (int) flag: write maps (and ideals) aligned

`TeXreplace` (list) list entries = 2 strings: replacing symbols

`NoDollars` (int) flag: suppresses surrounding \$ signs

Procedures:

D.9.2.1 closetex

Procedure from library `latex.lib` (see [Section D.9.2 \[latex.lib\]](#), page 1911).

Usage: `closetex(fname)`; `fname` string

Return: nothing; writes a LaTeX2e closing line into file `<fname>`.

Note: preceding ">>" are deleted and suffix ".tex" (if not given) is added to `fname`.

Example:

```

LIB "latex.lib";
opentex("exmpl");
texobj("exmpl","{\large \bf hello}");
closetex("exmpl");

```

D.9.2.2 opentex

Procedure from library `latex.lib` (see [Section D.9.2 \[latex.lib\]](#), page 1911).

Usage: `opentex(fname);` `fname` string

Return: nothing; writes a LaTeX2e header into a new file `<fname>`.

Note: preceding `>>` are deleted and suffix `.tex` (if not given) is added to `fname`.

Example:

```
LIB "latex.lib";
opentex("exmpl");
texobj("exmpl","hello");
closetex("exmpl");
```

D.9.2.3 tex

Procedure from library `latex.lib` (see [Section D.9.2 \[latex.lib\]](#), page 1911).

Usage: `tex(fname);` `fname` string

Return: nothing; calls `latex` (LaTeX2e) for compiling the file `fname`

Note: preceding `>>` are deleted and suffix `.tex` (if not given) is added to `fname`.

Example:

```
LIB "latex.lib";
ring r;
ideal I = maxideal(7);
opentex("exp001");           // open latex2e document
texobj("exp001","An ideal ",I);
closetex("exp001");
tex("exp001");
⇒ calling latex2e for: exp001.tex
⇒
⇒ This is pdfTeX, Version 3.14159265-2.6-1.40.18 (TeX Live 2017) (preloaded\
  format=latex)
⇒ restricted \write18 enabled.
⇒ entering extended mode
⇒ (./exp001.tex
⇒ LaTeX2e <2017/01/01> patch level 3
⇒ Babel <3.10> and hyphenation patterns for 3 language(s) loaded.
⇒ (/usr/share/texmf-dist/tex/latex/base/article.cls
⇒ Document Class: article 2014/09/29 v1.4h Standard LaTeX document class
⇒ (/usr/share/texmf-dist/tex/latex/base/size10.clo))
⇒ (/usr/share/texmf-dist/tex/latex/amsmath/amsmath.sty
⇒ For additional information on amsmath, use the '?' option.

```

D.9.2.4 texdemo

Procedure from library `latex.lib` (see [Section D.9.2 \[latex.lib\], page 1911](#)).

Usage: `texdemo();`

Return: nothing; generates a LaTeX2e file called `texlibdemo.tex` explaining the features of `latex.lib` and its global variables.

D.9.2.5 texfactorize

Procedure from library `latex.lib` (see [Section D.9.2 \[latex.lib\], page 1911](#)).

Usage: `texfactorize(fname,f);` `fname` string, `f` poly

Return: if `fname=""`: string, `f` as a product of its irreducible factors
otherwise: append this string to the file `<fname>`, and return nothing.

Note: preceding ">>" are deleted and suffix ".tex" (if not given) is added to `fname`.

Example:

```

LIB "latex.lib";
ring r2 = 13,(x,y),dp;
poly f = (x+1+y)^2*x3y*(2x-2y)*y12;
texfactorize("",f);
⇒ $-2\cdot (-x+y)\cdot (x+y+1)^2\cdot x^3\cdot y^{13}$
ring R49 = (7,a),x,dp;
minpoly = a2+a+3;
poly f = (a24x5+x3)*a2x6*(x+1)^2;
f;
⇒ (a+3)*x13+(2a-1)*x12+(-2a+1)*x10+(-a-3)*x9
texfactorize("",f);
⇒ $(a+3)\cdot (x-1)\cdot (x+1)^3\cdot x^9$

```

D.9.2.6 texmap

Procedure from library `latex.lib` (see [Section D.9.2 \[latex.lib\], page 1911](#)).

Usage: `texmap(fname,m,@r1,@r2);` `fname` string, `m` string/map, `@r1,@r2` rings

Return: if `fname=""`: string, the map `m` from `@r1` to `@r2` (preceded by its name if `m = string`) in TeX-typesetting;
otherwise: append this string to the file `<fname>`, and return nothing.

Note: preceding ">>" are deleted in `fname`, and suffix ".tex" (if not given) is added to `fname`.
If `m` is a string then it has to be the name of an existing map from `@r1` to `@r2`.

Example:

```

LIB "latex.lib";
// ----- prepare for example -----
if (defined(TeXaligned)) {int Teali=TeXaligned; kill TeXaligned;}
if (defined(TeXreplace)) {list Terep=TeXreplace; kill TeXreplace;}

```

```

// ----- the example starts here -----
//
string fname = "tldemo";
ring @r1=0,(x,y,z),dp;
export @r1;
ring r2=0,(u,v),dp;
map @phi =(@r1,u2,uv -v,v2); export @phi;
list TeXreplace;
TeXreplace[1] = list("@phi","\\phi"); // @phi --> \phi
export TeXreplace;
texmap("", "@phi", @r1, r2); // standard form
⇒ $$
⇒ \begin{array}{rcc}
⇒ \phi: \mathbb{Q}[x,y,z] & \xrightarrow{\quad} & \mathbb{Q}[u,v] \\
⇒ \left(x,y,z\right) & \xmapsto{\quad} & \\
⇒ \left( \right. \\
⇒ \begin{array}{c}
⇒ u^2 \\
⇒ uv-v \\
⇒ v^2 \\
⇒ \end{array} \\
⇒ \left. \right) \\
⇒ \end{array} \\
⇒ $$
//
int TeXaligned; export TeXaligned; // map in one line
texmap("", @phi, @r1, r2);
⇒ $\mathbb{Q}[x,y,z] \xrightarrow{\quad} \mathbb{Q}[u,v], \quad \left(x,y,z\right) \xmapsto{\quad} \left(u\right. \\
\quad \left.^2\right), uv-v, v^2 \left.\right)$
//
kill @r1, TeXreplace, TeXaligned;
//
// --- restore global variables if previously defined ---
if (defined(Teali)) {int TeXaligned=Teali; export TeXaligned; kill Teali;}
if (defined(Terep)) {list TeXreplace=Terep; export TeXreplace; kill Terep;}

```

D.9.2.7 texname

Procedure from library `latex.lib` (see [Section D.9.2 \[latex.lib\]](#), page 1911).

Usage: `texname(fname,s);` `fname,s` strings

Return: if `fname=""`: the transformed string `s`, for which the following rules apply:

<code>s' + "~"</code>	<code>--> "\\tilde{" + s' + "}"</code>
<code>"_" + int</code>	<code>--> "_{" + int + "}"</code>
<code>"[" + s' + "]"</code>	<code>--> "_{" + s' + "}"</code>
<code>"A..Z" + int</code>	<code>--> "A..Z" + "^{" + int + "}"</code>
<code>"a..z" + int</code>	<code>--> "a..z" + "_{" + int + "}"</code>
<code>"(" + int + "," + s' + ")"</code>	<code>--> "_{" + int + "}" + "^{" + s' + "}"</code>

Furthermore, strings which begin with a left brace are modified by deleting the first and the last character (which is then assumed to be a right brace).

if `fname!=""`: append the transformed string `s` to the file `<fname>`, and return nothing.

Note: preceding `">>"` are deleted in `fname`, and suffix `".tex"` (if not given) is added to `fname`.

Example:

```

LIB "latex.lib";
ring r = 0,(x,y),lp;
poly f = 3xy4 + 2xy2 + x5y3 + x + y6;
texname("", "{f(10)}");
⇒ f(10)
texname("", "f(10) =");
⇒ f_{10} =
texname("", "n1");
⇒ n_{1}
texname("", "T1_12");
⇒ T^{1}_{12}
texname("", "g'_{11}");
⇒ g'_{11}
texname("", "f23");
⇒ f_{23}
texname("", "M[2,3]");
⇒ M_{2,3}
texname("", "A(0,3);");
⇒ A_{0}^{3};
texname("", "E~(3)");
⇒ \tilde{E}_{3}

```

D.9.2.8 texobj

Procedure from library `latex.lib` (see [Section D.9.2 \[latex.lib\]](#), page 1911).

Usage: `texobj(fname,l);` `fname` string, `l` list

Return: if `fname=""`: string, the entries of `l` in LaTeX-typesetting;
otherwise: append this string to the file `<fname>`, and return nothing.

Note: preceding ">>" are deleted in `fname`, and suffix ".tex" (if not given) is added to `fname`.

Example:

```

LIB "latex.lib";
// ----- prepare for example -----
if (defined(TeXaligned)) {int Teali=TeXaligned; kill TeXaligned;}
if (defined(TeXbrack)){string Tebra=TeXbrack; kill TeXbrack;}
//
// ----- typesetting for polynomials -----
ring r = 0,(x,y),lp;
poly f = x5y3 + 3xy4 + 2xy2 + y6;
f;
⇒ x5y3+3xy4+2xy2+y6
texobj("",f);
⇒ $$
⇒ \begin{array}{r1}
⇒ & x^5y^3+3xy^4+2xy^2+y^6\\
⇒ \end{array}
⇒ $$
// ----- typesetting for ideals -----
ideal G = jacob(f);
G;
⇒ G[1]=5x4y3+3y4+2y2

```

```

⇒ G[2]=3x5y2+12xy3+4xy+6y5
texobj("",G);
⇒ $$
⇒ \left(
⇒ \begin{array}{c}
⇒ 5x^4y^3+3y^4+2y^2, \\
⇒ 3x^5y^2+12xy^3+4xy+6y^5
⇒ \end{array}
⇒ \right)$$
// ----- variation of typesetting for ideals -----
int TeXaligned = 1; export TeXaligned;
string TeXbrack = "<"; export TeXbrack;
texobj("",G);
⇒ $\left<5x^4y^3+3y^4+2y^2,3x^5y^2+12xy^3+4xy+6y^5\right>$
kill TeXaligned, TeXbrack;
// ----- typesetting for matrices -----
matrix J = jacob(G);
texobj("",J);
⇒ $$
⇒ \left(
⇒ \begin{array}{*{2}{c}}
⇒ 20x^3y^3 & 15x^4y^2+12y^3+4y \\
⇒ 15x^4y^2+12y^3+4y & 6x^5y+36xy^2+4x+30y^4
⇒ \end{array}
⇒ \right)
⇒ $$
// ----- typesetting for intmats -----
intmat m[3][4] = 9,2,4,5,2,5,-2,4,-6,10,-1,2,7;
texobj("",m);
⇒ $$
⇒ \left(
⇒ \begin{array}{*{4}{r}}
⇒ 9 & 2 & 4 & 5 \\
⇒ 2 & 5 & -2 & 4 \\
⇒ -6 & 10 & -1 & 2
⇒ \end{array}
⇒ \right)
⇒ $$
//
// --- restore global variables if previously defined ---
if (defined(Teali)){int TeXaligned=Teali; export TeXaligned; kill Teali;}
if (defined(Tebra)){string TeXbrack=Tebra; export TeXbrack; kill Tebra;}

```

D.9.2.9 texpoly

Procedure from library `latex.lib` (see [Section D.9.2 \[latex.lib\]](#), page 1911).

Usage: `texpoly(fname,p);` fname string, p poly

Return: if `fname=""`: string, the polynomial p in LaTeX-typesetting;
otherwise: append this string to the file `<fname>`, and return nothing.

Note: preceding `>>>` are deleted in `fname`, and suffix `.tex` (if not given) is added to `fname`.

Example:

```

LIB "latex.lib";
ring r0=0,(x,y,z),dp;
poly f = -1x^2 + 2;
texpoly("",f);
↪  $-\mathbf{x}^2+2$ 
ring rr= real,(x,y,z),dp;
texpoly("",2x2y23z);
↪  $2.000\mathbf{x}^2\mathbf{y}^{23}\mathbf{z}$ 
ring r7= 7,(x,y,z),dp;
poly f = 2x2y23z;
texpoly("",f);
↪  $2\mathbf{x}^2\mathbf{y}^{23}\mathbf{z}$ 
ring rab =(0,a,b),(x,y,z),dp;
poly f = (-2a2 +b3 -2)/a * x2y4z5 + (a2+1)*x + a+1;
f;
↪  $(-2a^2+b^3-2)/(a)*x^2y^4z^5+(a^2+1)*x+(a+1)$ 
texpoly("",f);
↪  $-\frac{2a^2-b^3+2}{a}\cdot x^2y^4z^5+(a^2+1)\cdot x+(a+1)$ 
texpoly("",1/(a2+2)*x2+2/b*x+(a+1)/3);
↪  $\frac{1}{a^2+2}\cdot x^2+\frac{2}{b}\cdot x+\frac{a+1}{3}$ 

```

D.9.2.10 texproc

Procedure from library `latex.lib` (see [Section D.9.2 \[latex.lib\]](#), page 1911).

Usage: `texproc(fname,pname);` fname,pname strings

Assume: 'pname' is a procedure.

Return: if `fname=""`: string, the proc 'pname' in a verbatim environment in LaTeX-typesetting;
otherwise: append this string to the file <fname>, and return nothing.

Note: preceding ">>" are deleted in `fname`, and suffix ".tex" (if not given) is added to `fname`.

Example:

```

LIB "latex.lib";
texproc("", "texproc");
↪ \begin{verbatim}
↪ proc texproc(string fname,string pname)
↪ {
↪   int i,j,k,nl;
↪   string @p,s,t;
↪
↪   j = 1;
↪
↪   if (defined('pname'))
↪   { if (typeof('pname')=="proc")
↪     { @p = string('pname');
↪       nl = find(@p,newline);
↪       s = "\\begin{verbatim}" + newline;
↪       s = s + "proc " + pname + "(";
↪       i = find(@p,"parameter");          // collecting the parameters
↪       k = find(@p,"alias");              // and the alias arguments
↪       while((i and i < nl) or (k and k < nl))

```

```

⇒      {
⇒      if (i and (k==0 or i<k))
⇒      {
⇒      j=find(@p,";",i);
⇒      t = @p[i+10,j-i-10];
⇒      if(i>1){s = s + ",";};
⇒      s = s + t;
⇒      }
⇒      if (k and (i==0 or k<i))
⇒      {
⇒      j=find(@p,";",k);
⇒      t = @p[k,j-k];
⇒      if(k>1){s = s + ",";};
⇒      s = s + t;
⇒      }
⇒      i = find(@p,"parameter",j);
⇒      k = find(@p,"alias",j);
⇒      }
⇒      s = s + ")" + newline;
⇒      j++; // skip one for the newline
⇒      i = find(@p,";"+"return();" + newline,j);
⇒      if (!(i))
⇒      { i = find(@p,";"+"RETURN();" + newline,j); } // j kann hier weg
⇒      s = s + "{" + @p[j,i-j-1] + "}" + newline;
⇒      s = s + "\\end{verbatim}" + newline;
⇒      }
⇒      }
⇒      else
⇒      { print(" // -- Error: No such proc defined");
⇒      return();
⇒      }
⇒      if(size(fname))
⇒      { i=1;
⇒      while (fname[i]==">"){i++;}
⇒      fname = fname[i,size(fname)-i+1];
⇒      if (size(fname)>=4) // check if filename is ending with ".tex"
⇒      { if(fname[size(fname)-3,4]!=".tex") {fname = fname + ".tex"; }
⇒      }
⇒      else {fname = fname + ".tex";}
⇒      write(fname,s);
⇒      }
⇒      else{return(s);}
⇒      }
⇒      \end{verbatim}
⇒

```

D.9.2.11 texring

Procedure from library `latex.lib` (see [Section D.9.2 \[latex.lib\]](#), page 1911).

Usage: `texring(fname, r[L]);` fname string, r ring, L list

Return: if `fname=""`: string, the ring in TeX-typesetting;
otherwise: append this string to the file `<fname>` and return nothing.

Note: preceding ">>" are deleted and suffix ".tex" (if not given) is added to `fname`.
The optional list `L` is assumed to be a list of strings which control, for instance the symbol for the field of coefficients.
For more details call `texdemo()`; (generates a LaTeX2e file called `texlibdemo.tex` which explains all features of `texring`).

Example:

```
LIB "latex.lib";
ring r0 = 0,(x,y),dp;           // char = 0, polynomial ordering
texring("",r0);
 $\mapsto \mathbb{Q}[x,y]$ 
//
ring r7 = 7,(x(0..2)),ds;       // char = 7, local ordering
texring("",r7);
 $\mapsto \mathbb{Z}_7[[x_0,x_1,x_2]]$ 
//
ring r1 = 0,(x1,x2,y1,y2),wp(1,2,3,4);
texring("",r1);
 $\mapsto \mathbb{Q}[x_1,x_2,y_1,y_2]$ 
//
ring rr = real,(x),dp;          // real numbers
texring("",rr);
 $\mapsto \mathbb{R}[x]$ 
//
ring rC = complex,x,dp;         // complex coefficients
texring("",rC);
 $\mapsto \mathbb{C}[x]$ 
//
ring rabc =(0,t1,t2,t3),(x,y),dp; // ring with parameters
texring("",rabc);
 $\mapsto \mathbb{Q}(t_1,t_2,t_3)[x,y]$ 
//
ring ralg = (7,a),(x1,x2),ds;    // algebraic extension
minpoly = a2-a+3;
texring("",ralg);
 $\mapsto \mathbb{Z}_7(a)[[x_1,x_2]]$ 
texring("",ralg,"mipo");
 $\mapsto \mathbb{Z}_7(a)/(a^2-a+3)[[x_1,x_2]]$ 
//
ring r49=(49,a),x,dp;           // Galois field
texring("",r49);
 $\mapsto \mathbb{F}_{49}[x]$ 
//
setring r0;                     // quotient ring
ideal i = x2-y3;
qring q = std(i);
texring("",q);
 $\mapsto \mathbb{Q}[x,y]/\left(y^3-x^2\right)$ 
//
// ----- additional features -----
ring r9 =0,(x(0..9)),ds;
texring("",r9,1);
 $\mapsto \mathbb{Q}[[x_0,\ldots,x_9]]$ 
```

```

texring("",r9,"C","{","^G");
⇒  $\mathbb{C}[x_0,x_1,x_2,x_3,x_4,x_5,x_6,x_7,x_8,x_9]^G$ 
//
ring rxy = 0,(x(1..5),y(1..6)),ds;
intvec v = 5,6;
texring("",rxy,v);
⇒  $\mathbb{Q}[x_1,\ldots,x_5,y_1,\ldots,y_6]$ 

```

D.9.2.12 rmx

Procedure from library `latex.lib` (see [Section D.9.2 \[latex.lib\]](#), page 1911).

Usage: `rmx(fname)`; fname string

Return: nothing; removes the `.log` and `.aux` files associated to the LaTeX file `<fname>`.

Note: If `fname` ends by `".dvi"` or `".tex"`, the `.dvi` or `.tex` file will be deleted, too.

Example:

```

LIB "latex.lib";
ring r;
poly f = x+y+z;
opentex("exp001");           // defaulted latex2e document
texobj("exp001","A polynom",f);
closetex("exp001");
tex("exp001");
⇒ calling latex2e for: exp001.tex
⇒
⇒ This is pdfTeX, Version 3.14159265-2.6-1.40.18 (TeX Live 2017) (preloaded\
    format=latex)

rmx("exp001"); // removes aux and log file of exp001
system("sh","rm exp001.*");
⇒ 0

```

D.9.2.13 xdvi

Procedure from library `latex.lib` (see [Section D.9.2 \[latex.lib\]](#), page 1911).

Usage: `xdvi(fname[,style]);` `fname,style = string`

Return: nothing; displays dvi-file `fname.dvi` with previewer `xdvi`

Note: suffix `.dvi` may be omitted in `fname`
`style` captures the program that will be called instead of the default (`xdvi`)

Example:

```
LIB "latex.lib";
intmat m[3][4] = 9,2,4,5,2,5,-2,4,-6,10,-1,2,7;
opentex("exp001");
texobj("exp001","An intmat: ",m);

⇒ 0
```

D.9.3 surf_lib

Library: `surf.lib`

Purpose: Procedures for Graphics with Surf

Author: Hans Schoenemann, Frank Seelisch

Note: Using this library requires the program `surf` to be installed. You can download `surf` either from <http://sourceforge.net/projects/surf> or from <ftp://jim.mathematik.uni-kl.de/pub/Math/Singular/utils/>. The procedure `surfer` requires the program `surfer` (version 1.4.1 or newer) to be installed. You can download `surfer` from <http://imaginary.org/program/surfer>

Procedures: See also: [Section D.9.4 \[surfex.lib\]](#), page 1923.

D.9.3.1 plot

Procedure from library `surf.lib` (see [Section D.9.3 \[surf.lib\]](#), page 1921).

Usage: `plot(I)`; `I` ideal or poly

Assume: `I` defines a plane curve or a surface given by one equation

Return: nothing

Note: requires the external program ‘`surf`’ to be installed, to close the graphical interface just press ‘`Q`’

Example:

```
LIB "surf.lib";
// ----- plane curves -----
ring rr0 = 0, (x1, x2), dp;
ideal I = x1^3 - x2^2;
plot(I);
ring rr1 = 0, (x, y, z), dp;
ideal I(1) = 2x^2 - 1/2x^3 + 1 - y + 1;
plot(I(1));
// ---- Singular Logo -----
poly logo = ((x+3)^3 + 2*(x+3)^2 - y^2)*(x^3 - y^2)*((x-3)^3 - 2*(x-3)^2 - y^2);
plot(logo);
// Steiner surface
ideal J(2) = x^2*y^2 + x^2*z^2 + y^2*z^2 - 17*x*y*z;
plot(J(2));
// -----
plot(x*(x^2 - y^2) + z^2);
// E7
plot(x^3 - x*y^3 + z^2);
// Whitney umbrella
plot(z^2 - x^2*y);
```

D.9.3.2 surfer

Procedure from library `surf.lib` (see [Section D.9.3 \[surf.lib\]](#), page 1921).

Usage: `surfer(f)`; `f` poly

Assume: `f` defines a surface given by one equation

Return: nothing

Note: requires the external program ‘`surfer`’ to be installed, to close the graphical interface just close the window of `surfer`

Example:

```

LIB "surf.lib";
ring rr1 = 0, (x,y,z), dp;
// Steiner surface
ideal J(2) = x^2*y^2+x^2*z^2+y^2*z^2-17*x*y*z;
surfer(J(2));
// -----
surfer(x*(x2-y2)+z2);
// E7
surfer(x^3-x*y^3+z^2);
// Whitney umbrella
surfer(z^2-x^2*y);

```

D.9.4 surfex.lib

Library: surfex.lib

Purpose: Procedures for visualizing and rotating surfaces.

Author: Oliver Labs
 This library uses the program surf
 (written by Stefan Endrass and others)
 and surfex (written by Oliver Labs and others, mainly Stephan Holzer).

Note: It is still an alpha version (see <http://www.AlgebraicSurface.net>)
 This library requires the program surfex, surf and java to be installed. The software is used for producing raytraced images of surfaces. You can download surfex from <http://www.surfex.AlgebraicSurface.net>
 surfex is a front-end for surf which aims to be easier to use than the original tool.

Procedures: See also: [Section D.9.3 \[surf.lib\]](#), page 1921.

D.9.4.1 plotRotated

Procedure from library `surfex.lib` (see [Section D.9.4 \[surfex.lib\]](#), page 1923).

Usage: `plotRotated(poly p, list coords, list #)`
 This opens the external program surfex for drawing the surface given by p, seen as a surface in the real affine space with coordinates coords. The optional int parameter can be used to set plotting quality.

Assume: coords is a list of three variables.
 The basering is of characteristic zero and without parameters.

Example:

```

LIB "surfex.lib";
"Example:";
// An easy example: a surface with four conical nodes.
ring r = 0, (x,y,z), dp;
poly cayley_cubic = x^3+y^3+z^3+1^3-1/4*(x+y+z+1)^3;
// plotRotated(cayley_cubic, list(x,y,z));
// A difficult example: a surface with a one-dimensional real component!
poly whitney_umbrella = x^2*z-y^2;
// The Whitney Umbrella without its handle:
plotRotated(whitney_umbrella, list(x,y,z));
// The Whitney Umbrella together with its handle:
plotRotated(whitney_umbrella, list(x,y,z), 2);

```

D.9.4.2 plotRot

Procedure from library `surfex.lib` (see [Section D.9.4 \[surfex.lib\]](#), page 1923).

Usage: `plotRot(poly p, list #)`
 Similar to `plotRotated`, but guesses automatically which coordinates should be used.
 The optional `int` parameter can be used to set plotting quality.
 It opens the external program `surfex` for drawing the surface given by `p`, seen as a surface in the real affine space with coordinates `coords`.

Assume: The basering is of characteristic zero and without parameters.

Example:

```
LIB "surfex.lib";
"Example:";
// More variables in the basering, but only 3 variables in the polynomial:
ring r1 = 0, (w,x,y,z), dp;
poly cayley_cubic = x^3+y^3+z^3+1^3-1/4*(x+y+z+1)^3;
plotRot(cayley_cubic);
// Three variables in the basering, but fewer variables in the polynomial:
ring r2 = 0, (x,y,z), dp;
plotRot(x^2+y^2-1);
plotRot(y^2+z^2-1);
// A cubic surface with a solitary point:
// Use the additional parameter 3 to ask singular
// to compute the singular locus before calling surfex.
ring r3 = 0, (x,y,z), dp;
poly kn_10 = x^3-3*x*y^2+z^3+3*x^2+3*y^2+z^2;
plotRot(kn_10, 3);
// The swallowtail:
// a surface with a real solitary curve sticking out of the surface.
// Use the additional parameter 3 to ask singular
// to compute the singular locus before calling surfex.
poly swallowtail = -4*y^2*z^3-16*x*z^4+27*y^4+144*x*y^2*z+128*x^2*z^2-256*x^3;
```

D.9.4.3 plotRotatedList

Procedure from library `surfex.lib` (see [Section D.9.4 \[surfex.lib\]](#), page 1923).

Usage: `plotRotatedList(list varieties, list coords, list #)`
 This opens the external program `surfex` for drawing the surfaces given by `varieties`, seen as a surface in the real affine space with coordinates `coords`. The optional `int` parameter can be used to set plotting quality.

Assume: `coords` is a list of three variables, `varieties` is a list of ideals describing the varieties to be shown.

The basering is of characteristic zero and without parameters.

Example:

```
LIB "surfex.lib";
"Example:";
// A cubic surface together with a tritangent plane
// (i.e. a plane which cuts out three lines).
ring r = 0, (x,y,z), dp;
poly cayley_cubic = x^3+y^3+z^3+1^3-1/4*(x+y+z+1)^3;
```

```

poly plane = 1-x-y-z;
plotRotatedList(list(cayley_cubic, plane), list(x,y,z));
// The same cubic and plane.
// The plane is not shown but only its intersection with the surface.
plotRotatedList(list(cayley_cubic, ideal(cayley_cubic, plane)), list(x,y,z));

```

D.9.4.4 plotRotatedDirect

Procedure from library `surfex.lib` (see [Section D.9.4 \[surfex.lib\]](#), page 1923).

Usage: `plotRotatedDirect(list varieties, list #)`
This opens the external program `surfex` for drawing the surfaces given by varieties, seen as a surface in the real affine space with coordinates x, y, z . The format for the list varieties is not fully documented yet; please, see the examples below and try to adjust the examples to suit your needs.
The optional `int` parameter can be used to set plotting quality.

Assume: Passes the equations directly to `surfex`, i.e., the variable names should be x, y, z .
The advantage is that one can use parameters p_1, p_2, \dots ; these will be passed to `surfex`.

Example:

```

LIB "surfex.lib";
"Example:";
// A cubic surface depending on a parameter:
ring r = (0,p1), (x,y,z), dp;
poly cayley_cubic = x^3+y^3+z^3+1^3-p1*(x+y+z+1)^3;
// The entries of the list of varieties can either be polynomials
plotRotatedDirect(list(list(list(cayley_cubic)),
list(),
list(list(1,"0.0","1.0","500","0.25+0.25*sin(PI*p1)"))
));
// or strings which represent surfex-readable polynomials
plotRotatedDirect(list(list(list("x^3+y^3+z^3+1^3-p1*(x+y+z+1)^3")),
list(),
list(list(1,"0.0","1.0","500","0.25+0.25*sin(PI*p1)"))
));
// More complicated varieties
plotRotatedDirect(list(list(list("x^2+y^2-z^2-3^2"),
list("x*sin(p1)+y*cos(p1)-3")),
list(list(list(1,2))),
list(list(1,"0.0","1.0","500","2*PI*p1"))
));

```

D.9.4.5 plotRotatedListFromSpecifyList

Procedure from library `surfex.lib` (see [Section D.9.4 \[surfex.lib\]](#), page 1923).

Usage: `plotRotatedListFromSpecifyList(list varietiesList, list #)`; `varietiesList` has a complicated format (not documented yet); see the example.
The optional `int` parameter can be used to set plotting quality.

Assume: The basering is of characteristic zero.

Example:

```

LIB "surfex.lib";
"Example:";
// A cubic surface depending on a parameter:
ring r = (0,p1), (x,y,z), dp;
poly cayley_cubic = x^3+y^3+z^3+1^3-p1*(x+y+z+1)^3;
poly plane = 1-x-y-z;
plotRotatedListFromSpecifyList(list(list(list(list("eqno:", "1"),
list("equation:",
string(cayley_cubic))
)
),
list(),
list(list(1, "0.0", "1.0", "500", "0.25+0.25*sin(PI*p1)")),
list()
));

```

D.10 Coding theory

D.10.1 brnoeth.lib

Library: brnoeth.lib

Purpose: Brill-Noether Algorithm, Weierstrass-SG and AG-codes

Authors: Jose Ignacio Farran Martin, ignfar@eis.uva.es
 Christoph Lossen, lossen@mathematik.uni-kl.de

Overview: Implementation of the Brill-Noether algorithm for solving the Riemann-Roch problem and applications to Algebraic Geometry codes. The computation of Weierstrass semi-groups is also implemented.

The procedures are intended only for plane (singular) curves defined over a prime field of positive characteristic.

For more information about the library see the end of the file brnoeth.lib.

Procedures:

D.10.1.1 Adj_div

Procedure from library `brnoeth.lib` (see [Section D.10.1 \[brnoeth.lib\]](#), page 1926).

Usage: Adj_div(f [,l]); f a poly, [l a list]

Return: list L with the computed data:

- L[1] a list of rings: L[1][1]=aff_r (affine), L[1][2]=Proj-R (projective),
- L[2] an intvec with 2 entries (degree, genus),
- L[3] a list of intvec (closed places),
- L[4] an intvec (conductor),
- L[5] a list of lists:
 - L[5][d][1] a (local) ring over an extension of degree d,
 - L[5][d][2] an intvec (degrees of base points of places of degree d)

Note: Adj_div(f); computes and stores the fundamental data of the plane curve defined by f as needed for AG codes.

In the affine ring you can find the following data:

poly CHI: affine equation of the curve,
 ideal Aff_SLocus: affine singular locus (std),
 list Inf_Points: points at infinity
 Inf_Points[1]: singular points
 Inf_Points[2]: non-singular points,
 list Aff_SPoints: affine singular points (if not empty).

In the projective ring you can find the projective equation CHI of the curve (poly).
 In the local rings $L[5][d][1]$ you find:

list POINTS: base points of the places of degree d ,
 list LOC_EQS: local equations of the curve at the base points,
 list BRANCHES: Hamburger-Noether developments of the places,
 list PARAMETRIZATIONS: local parametrizations of the places,

Each entry of the list $L[3]$ corresponds to one closed place (i.e., a place and all its conjugates) which is represented by an intvec of size two, the first entry is the degree of the place (in particular, it tells the local ring where to find the data describing one representative of the closed place), and the second one is the position of those data in the lists POINTS, etc., inside this local ring.

In the intvec $L[4]$ (conductor) the i -th entry corresponds to the i -th entry in the list of places $L[3]$.

With no optional arguments, the conductor is computed by local invariants of the singularities; otherwise it is computed by the Dedekind formula.

An affine point is represented by a list P where $P[1]$ is std of a prime ideal and $P[2]$ is an intvec containing the position of the places above P in the list of closed places $L[3]$.
 If the point is at infinity, $P[1]$ is a homogeneous irreducible polynomial in two variables.

If `printlevel` ≥ 0 additional comments are displayed (default: `printlevel=0`).

Warning: The parameter of the needed field extensions is called 'a'. Thus, there should be no global object named 'a' when executing `Adj_div`.

Example:

```
LIB "brnoeth.lib";
int plevel=printlevel;
printlevel=-1;
ring s=2,(x,y),lp;
list C=Adj_div(y9+y8+xy6+x2y3+y2+x3);
⇒ The genus of the curve is 3

printlevel=plevel;

```

See also: [Section D.10.1.2 \[NSplaces\], page 1929](#); [Section D.10.1.10 \[closed_points\], page 1939](#).

D.10.1.2 NSplaces

Procedure from library `brnoeth.lib` (see [Section D.10.1 \[brnoeth.lib\], page 1926](#)).

Usage: `NSplaces(h, CURVE)`, where `h` is an intvec and `CURVE` is a list

Return: list `L` with updated data of `CURVE` after computing all non-singular affine closed places whose degrees are in the intvec `h`:

```

in L[1][1]: (affine ring) lists Aff_Points(d) with affine non-singular
              (closed) points of degree d (if non-empty),
in L[3]:    the newly computed closed places are added,
in L[5]:    local rings created/updated to store (repres. of) new places.

```

See [Section D.10.1.1 \[Adj_div\], page 1926](#) for a description of the entries in `L`.

Note: The `list_expression` should be the output of the procedure `Adj_div`.
Raising `printlevel`, additional comments are displayed (default: `printlevel=0`).

Warning: The parameter of the needed field extensions is called `'a'`. Thus, there should be no global object named `'a'` when executing `NSplaces`.

Example:

```
LIB "brnoeth.lib";
```

```

int plevel=printlevel;
printlevel=-1;
ring s=2,(x,y),lp;
list C=Adj_div(x3y+y3+x);
⇒ The genus of the curve is 3
// The list of computed places:
C[3];

printlevel=plevel;

```

See also: [Section D.10.1.1 \[Adj_div\], page 1926](#); [Section D.10.1.10 \[closed_points\], page 1939](#).

D.10.1.3 BrillNoether

Procedure from library `brnoeth.lib` (see [Section D.10.1 \[brnoeth.lib\], page 1926](#)).

Usage: BrillNoether(G,CURVE); G an intvec, CURVE a list

Return: list of ideals (each of them with two homogeneous generators, which represent the numerator, resp. denominator, of a rational function).
The corresponding rational functions form a vector space basis of the linear system $L(G)$, G a rational divisor over a non-singular curve.

Note: The procedure must be called from the ring `CURVE[1][2]`, where CURVE is the output of the procedure `NSplaces`.

The intvec G represents a rational divisor supported on the closed places of `CURVE[3]` (e.g. `G=2,0,-1`; means 2 times the closed place 1 minus 1 times the closed place 3).

Example:

```

LIB "brnoeth.lib";
int plevel=printlevel;
printlevel=-1;
ring s=2,(x,y),lp;
list C=Adj_div(x3y+y3+x);
⇒ The genus of the curve is 3
C=NSplaces(1..4,C);
// the first 3 Places in C[3] are of degree 1.
// we define the rational divisor G = 4*C[3][1]+4*C[3][3] (of degree 8):
intvec G=4,0,4;
def R=C[1][2];
setring R;

```

```

list LG=BrillNoether(G,C);
↳ Vector basis successfully computed
// here is the vector basis of L(G):
LG;
↳ [1]:
↳   _[1]=1
↳   _[2]=1
↳ [2]:
↳   _[1]=y
↳   _[2]=x
↳ [3]:
↳   _[1]=z
↳   _[2]=x
↳ [4]:
↳   _[1]=y2
↳   _[2]=x2
↳ [5]:
↳   _[1]=xz2+y3
↳   _[2]=x3
↳ [6]:
↳   _[1]=xyz2+y4
↳   _[2]=x4
printlevel=plevel;

```

See also: [Section D.10.1.1 \[Adj_div\]](#), page 1926; [Section D.10.1.2 \[NSplaces\]](#), page 1929; [Section D.10.1.4 \[Weierstrass\]](#), page 1932.

D.10.1.4 Weierstrass

Procedure from library `brnoeth.lib` (see [Section D.10.1 \[brnoeth.lib\]](#), page 1926).

Usage: `Weierstrass(i, m, CURVE);` *i, m* integers and *CURVE* a list

Return: list WS of two lists:
 WS[1] list of integers (Weierstr. semigroup of the curve at place *i* up to *m*)
 WS[2] list of ideals (the associated rational functions)

Note: The procedure must be called from the ring `CURVE[1][2]`, where *CURVE* is the output of the procedure `NSplaces`.
 i represents the place `CURVE[3][i]`.
 Rational functions are represented by numerator/denominator in form of ideals with two homogeneous generators.

Warning: The place must be rational, i.e., necessarily `CURVE[3][i][1]=1`.

Example:

```

LIB "brnoeth.lib";
int plevel=printlevel;
printlevel=-1;
ring s=2,(x,y),lp;
list C=Adj_div(x3y+y3+x);
↳ The genus of the curve is 3
C=NSplaces(1..4,C);

```

```

def R=C[1][2];
setring R;
// Place C[3][1] has degree 1 (i.e it is rational);
list WS=Weierstrass(1,7,C);
⇒ Vector basis successfully computed
// the first part of the list is the Weierstrass semigroup up to 7 :
WS[1];
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 3
⇒ [3]:
⇒ 5
⇒ [4]:
⇒ 6
⇒ [5]:
⇒ 7
// and the second part are the corresponding functions :
WS[2];
⇒ [1]:
⇒ _[1]=1
⇒ _[2]=1
⇒ [2]:
⇒ _[1]=y
⇒ _[2]=z
⇒ [3]:
⇒ _[1]=xy
⇒ _[2]=z2
⇒ [4]:
⇒ _[1]=y2
⇒ _[2]=z2
⇒ [5]:
⇒ _[1]=y3
⇒ _[2]=xz2
printlevel=plevel;

```

See also: [Section D.10.1.1 \[Adj_div\]](#), page 1926; [Section D.10.1.3 \[BrillNoether\]](#), page 1931; [Section D.10.1.2 \[NSplaces\]](#), page 1929.

D.10.1.5 extcurve

Procedure from library `brnoeth.lib` (see [Section D.10.1 \[brnoeth.lib\]](#), page 1926).

Usage: `extcurve(d, CURVE);` d an integer, CURVE a list

Return: list L which is the update of the list CURVE with additional entries

```

L[1][3]: ring (p,a),(x,y),lp (affine),
L[1][4]: ring (p,a),(x,y,z),lp (projective),
L[1][5]: ring (p,a),(x,y,t),ls (local),
L[2][3]: int (the number of rational places),

```

the rings being defined over a field extension of degree d.

If $d < 2$ then `extcurve(d,CURVE)`; creates a list L which is the update of the list CURVE with additional entries

```

L[1][5]: ring p,(x,y,t),ls,
L[2][3]: int (the number of computed places over the base field).

```

In both cases, in the ring `L[1][5]` lists with the data for all the computed rational places (after a field extension of degree `d`) are created (see [Section D.10.1.1 \[Adj_div\]](#), page 1926):

lists POINTS, LOC_EQS, BRANCHES, PARAMETRIZATIONS.

Note: The list `CURVE` should be the output of `NSplaces`, and must contain (at least) one place of degree `d`.
 You actually need all the places with degree dividing `d`. Otherwise, not all the places are computed, but only part of them.
 This procedure must be executed before constructing AG codes, even if no extension is needed. The ring `L[1][4]` must be active when constructing codes over the field extension.

Example:

```

LIB "brnoeth.lib";
int plevel=printlevel;
printlevel=-1;
ring s=2,(x,y),lp;
list C=Adj_div(x5+y2+y);
↳ The genus of the curve is 2
C=NSplaces(1..4,C);
// since we have all points up to degree 4, we can extend the curve
// to that extension, in order to get rational points over F_16;
C=extcurve(4,C);
↳ Total number of rational places : NrRatPl = 33
// e.g., display the basepoint of place no. 32:
def R=C[1][5];
setring R;

See also: [Section D.10.1.6 \[AGcode_L\]](#), page 1934; [Section D.10.1.7 \[AGcode_Omega\]](#), page 1935; [Section D.10.1.1 \[Adj_div\]](#), page 1926; [Section D.10.1.2 \[NSplaces\]](#), page 1929; [Section D.10.1.10 \[closed_points\]](#), page 1939.

D.10.1.6 AGcode_L

Procedure from library `brnoeth.lib` (see [Section D.10.1 \[brnoeth.lib\]](#), page 1926).

Usage: `AGcode_L(G, D, EC);` `G,D` intvec, `EC` a list

Return: a generator matrix for the evaluation AG code defined by the divisors `G` and `D`.

- Note:** The procedure must be called within the ring $EC[1][4]$, where EC is the output of `extcurve(d)` (or within the ring $EC[1][2]$ if $d=1$).
The entry i in the intvec D refers to the i -th rational place in $EC[1][5]$ (i.e., to $POINTS[i]$, etc., see [Section D.10.1.5 \[extcurve\]](#), page 1933).
The intvec G represents a rational divisor (see [Section D.10.1.3 \[BrillNoether\]](#), page 1931 for more details).
The code evaluates the vector space basis of $L(G)$ at the rational places given by D .
- Warnings:** G should satisfy $2 * genus - 2 < deg(G) < size(D)$, which is not checked by the algorithm.
 G and D should have disjoint supports (checked by the algorithm).

Example:

```
LIB "brnoeth.lib";
int plevel=printlevel;
printlevel=-1;
ring s=2,(x,y),lp;
list HC=Adj_div(x3+y2+y);
→ The genus of the curve is 1
HC=NSplaces(1..2,HC);
HC=extcurve(2,HC);
→ Total number of rational places : NrRatPl = 9
def ER=HC[1][4];
setring ER;
intvec G=5;      // the rational divisor G = 5*HC[3][1]
intvec D=2..9;   // D = sum of the rational places no. 2..9 over F_4
// let us construct the corresponding evaluation AG code :
matrix C=AGcode_L(G,D,HC);
→ Vector basis successfully computed
// here is a linear code of type [8,5,>=3] over F_4
print(C);
→ 0,0,1, 1, (a), (a+1),(a+1),(a),
→ 0,1,(a),(a+1),(a), (a+1),(a), (a+1),
→ 1,1,1, 1, 1, 1, 1, 1,
→ 0,0,1, 1, (a+1),(a), (a), (a+1),
→ 0,0,(a),(a+1),(a+1),(a), 1, 1
printlevel=plevel;
```

See also: [Section D.10.1.7 \[AGcode_Omega\]](#), page 1935; [Section D.10.1.1 \[Adj_div\]](#), page 1926; [Section D.10.1.3 \[BrillNoether\]](#), page 1931; [Section D.10.1.5 \[extcurve\]](#), page 1933.

D.10.1.7 AGcode_Omega

Procedure from library `brnoeth.lib` (see [Section D.10.1 \[brnoeth.lib\]](#), page 1926).

- Usage:** `AGcode_Omega(G, D, EC);` G, D intvec, EC a list
- Return:** a generator matrix for the residual AG code defined by the divisors G and D .
- Note:** The procedure must be called within the ring $EC[1][4]$, where EC is the output of `extcurve(d)` (or within the ring $EC[1][2]$ if $d=1$).
The entry i in the intvec D refers to the i -th rational place in $EC[1][5]$ (i.e., to $POINTS[i]$, etc., see [Section D.10.1.5 \[extcurve\]](#), page 1933).
The intvec G represents a rational divisor (see [Section D.10.1.3 \[BrillNoether\]](#), page 1931 for more details).
The code computes the residues of a vector space basis of

$\Omega(G - D)$ at the rational places given by D .

Warnings: G should satisfy $2 * \text{genus} - 2 < \deg(G) < \text{size}(D)$, which is not checked by the algorithm.

G and D should have disjoint supports (checked by the algorithm).

Example:

```
LIB "brnoeth.lib";
int plevel=printlevel;
printlevel=-1;
ring s=2,(x,y),lp;
list HC=Adj_div(x3+y2+y);
↳ The genus of the curve is 1
HC=NSplaces(1..2,HC);
HC=extcurve(2,HC);
↳ Total number of rational places : NrRatPl = 9
def ER=HC[1][4];
setring ER;
intvec G=5;      // the rational divisor G = 5*HC[3][1]
intvec D=2..9;   // D = sum of the rational places no. 2..9 over F_4
// let us construct the corresponding residual AG code :
matrix C=AGcode_Omega(G,D,HC);
↳ Vector basis successfully computed
// here is a linear code of type [8,3,>=5] over F_4
print(C);
↳ 1,      0,      (a),(a+1),1,1,0,0,
↳ (a+1),(a),  1,  0,      1,0,1,0,
↳ (a+1),(a+1),(a),(a),  1,0,0,1
printlevel=plevel;
```

See also: [Section D.10.1.6 \[AGcode_L\]](#), page 1934; [Section D.10.1.1 \[Adj_div\]](#), page 1926; [Section D.10.1.3 \[BrillNoether\]](#), page 1931; [Section D.10.1.5 \[extcurve\]](#), page 1933.

D.10.1.8 prepSV

Procedure from library `brnoeth.lib` (see [Section D.10.1 \[brnoeth.lib\]](#), page 1926).

Usage: `prepSV(G, D, F, EC);` G, D, F intvecs and EC a list

Return: list E of size $n+3$, where $n=\text{size}(D)$. All its entries but $E[n+3]$ are matrices:

$E[1]$: parity check matrix for the current AG code
 $E[2] \dots E[n+2]$: matrices used in the procedure `decodeSV`
 $E[n+3]$: intvec with
 $E[n+3][1]$: correction capacity

epsilon
of the algorithm
 $E[n+3][2]$: designed Goppa distance

delta
of the current AG code

Note: Computes the preprocessing for the basic (Skorobogatov-Vladut) decoding algorithm. The procedure must be called within the ring $EC[1][4]$, where EC is the output of `extcurve(d)` (or in the ring $EC[1][2]$ if $d=1$)
The intvec G and F represent rational divisors (see [Section D.10.1.3 \[BrillNoether\]](#), [page 1931](#) for more details).
The intvec D refers to rational places (see [Section D.10.1.7 \[AGcode_Omega\]](#), [page 1935](#) for more details). The current AG code is `AGcode_Omega(G,D,EC)`.
If you know the exact minimum distance d and you want to use it in `decodeSV` instead of `delta`, you can change the value of $E[n+3][2]$ to d before applying `decodeSV`.
If you have a systematic encoding for the current code and want to keep it during the decoding, you must previously permute D (using `permute_L(D,P)`), e.g., according to the permutation $P=L[3]$, L being the output of `sys_code`.

Warnings: F must be a divisor with support disjoint from the support of D and with degree $\epsilon + \text{genus}$, where
 $\epsilon := \lfloor (\deg(G) - 3 * \text{genus} + 1) / 2 \rfloor$.
 G should satisfy $2 * \text{genus} - 2 < \deg(G) < \text{size}(D)$, which is not checked by the algorithm.
 G and D should also have disjoint supports (checked by the algorithm).

Example:

```
LIB "brnoeth.lib";
int plevel=printlevel;
printlevel=-1;
ring s=2,(x,y),lp;
list HC=Adj_div(x^3+y^2+y);
→ The genus of the curve is 1
HC=NSplaces(1..2,HC);
HC=extcurve(2,HC);
→ Total number of rational places : NrRatPl = 9
def ER=HC[1][4];
setring ER;
intvec G=5;      // the rational divisor G = 5*HC[3][1]
intvec D=2..9;   // D = sum of the rational places no. 2..9 over F_4
// construct the corresp. residual AG code of type [8,3,>=5] over F_4:
matrix C=AGcode_Omega(G,D,HC);
→ Vector basis successfully computed
// we can correct 1 error and the genus is 1, thus F must have degree 2
// and support disjoint from that of D;
intvec F=2;
list SV=prepSV(G,D,F,HC);
→ Vector basis successfully computed
→ Vector basis successfully computed
→ Vector basis successfully computed
// now everything is prepared to decode with the basic algorithm;
// for example, here is a parity check matrix to compute the syndrome :
print(SV[1]);
→ 0,0,1, 1,    (a),  (a+1),(a+1),(a),
→ 0,1,(a),(a+1),(a),  (a+1),(a),  (a+1),
→ 1,1,1, 1,    1,    1,    1,    1,
→ 0,0,1, 1,    (a+1),(a),  (a),  (a+1),
→ 0,0,(a),(a+1),(a+1),(a),  1,    1
// and here you have the correction capacity of the algorithm :
```

```

int epsilon=SV[size(D)+3][1];
epsilon;
↪ 1
printlevel=plevel;

```

See also: [Section D.10.1.7 \[AGcode_Omega\]](#), page 1935; [Section D.10.1.9 \[decodeSV\]](#), page 1938; [Section D.10.1.5 \[extcurve\]](#), page 1933; [Section D.10.1.13 \[permute_L\]](#), page 1941; [Section D.10.1.12 \[sys_code\]](#), page 1940.

D.10.1.9 decodeSV

Procedure from library `brnoeth.lib` (see [Section D.10.1 \[brnoeth.lib\]](#), page 1926).

Usage: `decodeSV(y, K);` `y` a row-matrix and `K` a list

Return: a codeword (row-matrix) if possible, resp. the 0-matrix (of size 1) if decoding is impossible.
For decoding the basic (Skorobogatov-Vladut) decoding algorithm is applied.

Note: The `list_expression` should be the output `K` of the procedure `prepSV`.
The `matrix_expression` should be a $(1 \times n)$ -matrix, where $n = \text{ncols}(K[1])$.
The decoding may fail if the number of errors is greater than the correction capacity of the algorithm.

Example:

```

LIB "brnoeth.lib";
int plevel=printlevel;
printlevel=-1;
ring s=2,(x,y),lp;
list HC=Adj_div(x3+y2+y);
↪ The genus of the curve is 1
HC=NSplaces(1..2,HC);
HC=extcurve(2,HC);
↪ Total number of rational places : NrRatPl = 9
def ER=HC[1][4];
setring ER;
intvec G=5; // the rational divisor G = 5*HC[3][1]
intvec D=2..9; // D = sum of the rational places no. 2..9 over F_4
// construct the corresp. residual AG code of type [8,3,>=5] over F_4:
matrix C=AGcode_Omega(G,D,HC);
↪ Vector basis successfully computed
// we can correct 1 error and the genus is 1, thus F must have degree 2
// and support disjoint from that of D
intvec F=2;
list SV=prepSV(G,D,F,HC);
↪ Vector basis successfully computed
↪ Vector basis successfully computed
↪ Vector basis successfully computed
// now we produce 1 error on the zero-codeword :
matrix y[1][8];
y[1,3]=a;
// and then we decode :
print(decodeSV(y,SV));
↪ 0,0,0,0,0,0,0,0
printlevel=plevel;

```

See also: [Section D.10.1.7 \[AGcode_Omega\]](#), page 1935; [Section D.10.1.5 \[extcurve\]](#), page 1933; [Section D.10.1.8 \[prepSV\]](#), page 1936.

D.10.1.10 closed_points

Procedure from library `brnoeth.lib` (see [Section D.10.1 \[brnoeth.lib\]](#), page 1926).

Usage: `closed_points(I)`; I an ideal

Return: list of prime ideals (each a Groebner basis), corresponding to the (distinct affine closed) points of $V(I)$

Note: The ideal must have dimension 0, the basering must have 2 variables, the ordering must be `lp`, and the base field must be finite and prime.
It might be convenient to set the option(`redSB`) in advance.

Example:

```
LIB "brnoeth.lib";
ring s=2,(x,y),lp;
// this is just the affine plane over F_4 :
ideal I=x4+x,y4+y;
list L=closed_points(I);
// and here you have all the points :
L;
⇒ [1]:
⇒   _[1]=y
⇒   _[2]=x
⇒ [2]:
⇒   _[1]=y
⇒   _[2]=x+1
⇒ [3]:
⇒   _[1]=y
⇒   _[2]=x2+x+1
⇒ [4]:
⇒   _[1]=y+1
⇒   _[2]=x
⇒ [5]:
⇒   _[1]=y+1
⇒   _[2]=x+1
⇒ [6]:
⇒   _[1]=y+1
⇒   _[2]=x2+x+1
⇒ [7]:
⇒   _[1]=y2+y+1
⇒   _[2]=x
⇒ [8]:
⇒   _[1]=y2+y+1
⇒   _[2]=x+1
⇒ [9]:
⇒   _[1]=y2+y+1
⇒   _[2]=x+y
⇒ [10]:
⇒   _[1]=y2+y+1
⇒   _[2]=x+y+1
```

See also: [Section D.8.5 \[triang.lib\]](#), page 1860.

D.10.1.11 dual_code

Procedure from library `brnoeth.lib` (see [Section D.10.1 \[brnoeth.lib\], page 1926](#)).

Usage: `dual_code(G)`; G a matrix of numbers

Return: a generator matrix of the dual code generated by G

Note: The input should be a matrix G of numbers.
The output is also a parity check matrix for the code defined by G

Example:

```
LIB "brnoeth.lib";
ring s=2,T,lp;
// here is the Hamming code of length 7 and dimension 3
matrix G[3][7]=1,0,1,0,1,0,1,0,1,1,0,0,1,1,0,0,0,1,1,1,1;
print(G);
  ↪ 1,0,1,0,1,0,1,
  ↪ 0,1,1,0,0,1,1,
  ↪ 0,0,0,1,1,1,1
matrix H=dual_code(G);
print(H);
  ↪ 1,1,1,0,0,0,0,
  ↪ 1,0,0,1,1,0,0,
  ↪ 0,1,0,1,0,1,0,
  ↪ 1,1,0,1,0,0,1
```

D.10.1.12 sys_code

Procedure from library `brnoeth.lib` (see [Section D.10.1 \[brnoeth.lib\], page 1926](#)).

Usage: `sys_code(C)`; C is a matrix of constants

Return: list L with:

$L[1]$ is the generator matrix in standard form of an equivalent code,
 $L[2]$ is the parity check matrix in standard form of such code,
 $L[3]$ is an intvec which represents the needed permutation.

Note: Computes a systematic code which is equivalent to the given one.

The input should be a matrix of numbers.

The output has to be interpreted as follows: if the input was the generator matrix of an AG code then one should apply the permutation $L[3]$ to the divisor D of rational points by means of `permute_L(D,L[3])`; before continuing to work with the code (for instance, if you want to use the systematic encoding together with a decoding algorithm).

Example:

```
LIB "brnoeth.lib";
ring s=3,T,lp;
matrix C[2][5]=0,1,0,1,1,0,1,0,0,1;
print(C);
  ↪ 0,1,0,1,1,
  ↪ 0,1,0,0,1
list L=sys_code(C);
L[3];
```

```

⇒ 2,4,3,1,5
// here is the generator matrix in standard form
print(L[1]);
⇒ 1,0,0,0,1,
⇒ 0,1,0,0,0
// here is the control matrix in standard form
print(L[2]);
⇒ 0, 0,1,0,0,
⇒ 0, 0,0,1,0,
⇒ -1,0,0,0,1
// we can check that both codes are dual to each other
print(L[1]*transpose(L[2]));
⇒ 0,0,0,
⇒ 0,0,0

```

See also: [Section D.10.1.7 \[AGcode_Omega\]](#), page 1935; [Section D.10.1.13 \[permute_L\]](#), page 1941; [Section D.10.1.8 \[prepSV\]](#), page 1936.

D.10.1.13 permute_L

Procedure from library `brnoeth.lib` (see [Section D.10.1 \[brnoeth.lib\]](#), page 1926).

Usage: `permute_L(L, P)`; L,P either intvecs or lists

Return: list obtained from L by applying the permutation given by P.

Note: If P is a list, all entries must be integers.

Example:

```

LIB "brnoeth.lib";
list L=list();
L[1]="a";
L[2]="b";
L[3]="c";
L[4]="d";
intvec P=1,3,4,2;
// the list L is permuted according to P :
permute_L(L,P);
⇒ [1]:
⇒ a
⇒ [2]:
⇒ c
⇒ [3]:
⇒ d
⇒ [4]:
⇒ b

```

See also: [Section D.10.1.7 \[AGcode_Omega\]](#), page 1935; [Section D.10.1.8 \[prepSV\]](#), page 1936; [Section D.10.1.12 \[sys_code\]](#), page 1940.

D.10.2 decodegb_lib

Library: `decodegb.lib`

Purpose: Decoding and min distance of linear codes with GB

Author: Stanislav Bulygin, bulygin@mathematik.uni-kl.de

Overview: In this library we generate several systems used for decoding cyclic codes and finding their minimum distance. Namely, we work with the Cooper's philosophy and generalized Newton identities. The origideal method of quadratic equations is worked out here as well. We also (for comparison) enable to work with the system of Fitzgerald-Lax. We provide some auxiliary functions for further manipulations and decoding. For an overview of the methods mentioned above [Section C.8 \[Decoding codes with Groebner bases\]](#), page 785. For the vanishing ideal computation the algorithm of Farr and Gao is implemented.

Procedures:

D.10.2.1 sysCRHT

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\]](#), page 1941).

Usage: `sysCRHT(n,defset,e,q,m,[k]);` `n,e,q,m,k` are int, `defset` list of int's

- `n` length of the cyclic code,
- `defset` is a list representing the defining set,
- `e` the error-correcting capacity,
- `q` field size
- `m` degree extension of the splitting field,
- if `k>0` additional equations representing the fact that every two error positions are either different or at least one of them is zero

Return: the ring to work with the CRHT-ideal (with Sala's additions), containing an ideal with name 'crht'

Theory: Based on 'defset' of the given cyclic code, the procedure constructs the corresponding Cooper-Reed-Heleseth-Truong ideal 'crht'. With its help one can solve the decoding problem. For basics of the method [Section C.8.2 \[Cooper philosophy\]](#), page 787.

Example:

```
LIB "decodegb.lib";
// binary cyclic [15,7,5] code with defining set (1,3)
intvec v = option(get);
list defset=1,3;           // defining set
int n=15;                  // length
int e=2;                   // error-correcting capacity
int q=2;                   // basefield size
int m=4;                   // degree extension of the splitting field
int sala=1;                // indicator to add additional equations
def A=sysCRHT(n,defset,e,q,m);
setring A;
A;                          // shows the ring we are working in
⇒ // coefficients: ZZ/2(a)
⇒ // number of vars : 6
⇒ //          block 1 : ordering lp
⇒ //          : names   Y(2) Y(1) Z(1) Z(2) X(2) X(1)
⇒ //          block 2 : ordering C
print(crht);                // the CRHT-ideal
⇒ Y(2)*Z(2)+Y(1)*Z(1)+X(1),
⇒ Y(2)*Z(2)^3+Y(1)*Z(1)^3+X(2),
⇒ X(1)^16+X(1),
⇒ X(2)^16+X(2),
⇒ Z(1)^16+Z(1),
```

```

⇒ Z(2)^16+Z(2),
⇒ Y(1)+1,
⇒ Y(2)+1
option(redSB);
ideal red_crht=std(crht); // reduced Groebner basis
print(red_crht);
⇒ X(1)^16+X(1),
⇒ X(2)*X(1)^15+X(2),
⇒ X(2)^8+X(2)^4*X(1)^12+X(2)^2*X(1)^3+X(2)*X(1)^6,
⇒ Z(2)^2*X(1)+Z(2)*X(1)^2+X(2)+X(1)^3,
⇒ Z(2)^2*X(2)+Z(2)*X(2)*X(1)+X(2)^2*X(1)^14+X(2)*X(1)^2,
⇒ Z(2)^16+Z(2),
⇒ Z(1)+Z(2)+X(1),
⇒ Y(1)+1,
⇒ Y(2)+1
//=====
A=sysCRHT(n,defset,e,q,m,sala);
setring A;

⇒ Y(2)*Z(2)^3+Y(1)*Z(1)^3+X(2),
⇒ X(1)^16+X(1),
⇒ X(2)^16+X(2),
⇒ Z(1)^16+Z(1),
⇒ Z(2)^16+Z(2),
⇒ Y(1)+1,
⇒ Y(2)+1,
⇒ Z(1)^15*Z(2)+Z(1)^14*Z(2)^2+Z(1)^13*Z(2)^3+Z(1)^12*Z(2)^4+Z(1)^11*Z(2)^5+
   Z(1)^10*Z(2)^6+Z(1)^9*Z(2)^7+Z(1)^8*Z(2)^8+Z(1)^7*Z(2)^9+Z(1)^6*Z(2)^10+Z(1)^5*Z(2)^11+
   Z(1)^4*Z(2)^12+Z(1)^3*Z(2)^13+Z(1)^2*Z(2)^14+Z(1)*Z(2)^15
option(redSB);
ideal red_crht=std(crht); // reduced Groebner basis
print(red_crht);
⇒ X(1)^16+X(1),
⇒ X(2)*X(1)^15+X(2),
⇒ X(2)^8+X(2)^4*X(1)^12+X(2)^2*X(1)^3+X(2)*X(1)^6,
⇒ Z(2)*X(1)^15+Z(2),
⇒ Z(2)^2+Z(2)*X(1)+X(2)*X(1)^14+X(1)^2,
⇒ Z(1)+Z(2)+X(1),
⇒ Y(1)+1,
⇒ Y(2)+1
red_crht[5]; // general error-locator polynomial for this code
⇒ Z(2)^2+Z(2)*X(1)+X(2)*X(1)^14+X(1)^2
option(set,v);

```

See also: [Section D.10.2.4 \[sysBin\]](#), page 1948; [Section D.10.2.3 \[sysNewton\]](#), page 1945.

D.10.2.2 sysCRHTMindist

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\]](#), page 1941).

Usage: `sysCRHTMindist(n,defset,w);` `n,w` are int, `defset` is list of int's

- `n` length of the cyclic code,
- `defset` is a list representing the defining set,

- w is a candidate for the minimum distance

Return: the ring to work with the Sala's ideal for the minimum distance containing the ideal with name 'crht_md'

Theory: Based on 'defset' of the given cyclic code, the procedure constructs the corresponding Cooper-Reed-Heleseth-Truong ideal 'crht_md'. With its help one can find minimum distance of the code in the binary case. For basics of the method [Section C.8.2 \[Cooper philosophy\], page 787](#).

Example:

```
LIB "decodegb.lib";
intvec v = option(get);
// binary cyclic [15,7,5] code with defining set (1,3)
list defset=1,3;          // defining set
int n=15;                  // length
int d=5;                   // candidate for the minimum distance
def A=sysCRHTMindist(n,defset,d);
setring A;
A;                          // shows the ring we are working in
⇒ // coefficients: ZZ/2
⇒ // number of vars : 5
⇒ //      block 1 : ordering lp
⇒ //      : names  Z(1) Z(2) Z(3) Z(4) Z(5)
⇒ //      block 2 : ordering C
print(crht_md);             // the Sala's ideal for mindist

D.10.2.3 sysNewton

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\]](#), page 1941).

Usage: `sysNewton (n,defset,t,q,m,[tr]);` n, t, q, m, tr int, `defset` is list int's

- n is length,
- `defset` is the defining set,
- t is the number of errors,
- q is basefield size,
- m is degree extension of the splitting field,
- if $tr > 0$ it indicates that Newton identities in triangular form should be constructed

Return: the ring to work with the generalized Newton identities (in triangular form if applicable) containing the ideal with name 'newton'

Theory: Based on 'defset' of the given cyclic code, the procedure constructs the corresponding ideal 'newton' with the generalized Newton identities. With its help one can solve the decoding problem. For basics of the method [Section C.8.3 \[Generalized Newton identities\]](#), page 788.

Example:

```

LIB "decodegb.lib";
// Newton identities for a binary 3-error-correcting cyclic code of
//length 31 with defining set (1,5,7)

```

```

int n=31;          // length
list defset=1,5,7; //defining set
int t=3;          // number of errors
int q=2;          // basefield size
int m=5;          // degree extension of the splitting field
int tr=1;         // indicator of triangular form of Newton identities
def A=sysNewton(n,defset,t,q,m);

D.10.2.4 sysBin

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\]](#), page 1941).

Usage: `sysBin (v,Q,n,[odd]);` v,n,odd are int, Q is list of int's

- v a number if errors,
- Q is a defining set of the code,
- n the length,
- odd is an additional parameter: if
set to 1, then the defining set is enlarged by odd elements,
which are $2^{(\text{some power})} * (\text{some element in the def.set}) \bmod n$

Return: the ring with the resulting system called 'bin'

Theory: Based on Q of the given cyclic code, the procedure constructs the corresponding ideal 'bin' with the use of the Waring function. With its help one can solve the decoding problem. For basics of the method [Section C.8.3 \[Generalized Newton identities\]](#), [page 788](#).

Example:

```
LIB "decodegb.lib";
// [31,16,7] quadratic residue code
list l=1,5,7,9,19,25;
// we do not need even synromes here
def A=sysBin(3,l,31);

D.10.2.5 encode

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\]](#), [page 1941](#)).

Usage: encode (x, g); x a row vector (message), and g a generator matrix

Return: corresponding codeword

Example:

```
LIB "decodegb.lib";
ring r=2,x,dp;
matrix x[1][4]=1,0,1,0;
matrix g[4][7]=1,0,0,0,0,1,1,
0,1,0,0,1,0,1,
0,0,1,0,1,1,1,
0,0,0,1,1,1,0;
//encode x with the generator matrix g
print(encode(x,g));
↦ 1,0,1,0,1,0,0
```

D.10.2.6 syndrome

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\]](#), page 1941).

Usage: syndrome (h, c); h a check matrix, c a row vector (codeword)

Return: corresponding syndrome

Example:

```
LIB "decodegb.lib";
ring r=2,x,dp;
matrix x[1][4]=1,0,1,0;
matrix g[4][7]=1,0,0,0,0,1,1,
0,1,0,0,1,0,1,
0,0,1,0,1,1,1,
0,0,0,1,1,1,0;
//encode x with the generator matrix g
matrix c=encode(x,g);
// disturb
c[1,3]=0;
//compute syndrome
//corresponding check matrix
matrix check[3][7]=1,0,0,1,1,0,1,0,1,0,1,0,1,1,0,0,1,0,1,1,1;
print(syndrome(check,c));
↦ 0,
↦ 0,
↦ 1
c[1,3]=1;
//now c is a codeword
print(syndrome(check,c));
↦ 0,
↦ 0,
↦ 0
```

D.10.2.7 sysQE

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\]](#), page 1941).

Usage: sysQE(check,y,t,[feldeq,formal]); check,y matrix;t,feldeq,formal int

- check is a parity check matrix of the code
- y is a received word,

- t the number of errors to be corrected,
- if fieldeg=1, then field equations are added,
- if formal=0, field equations on (known) syndrome variables are not added, in order to add them (note that the exponent should be equal to the number of elements in the INITIAL alphabet) one needs to set formal>0 for the exponent

Return: the ring to work with together with the resulting system called 'qe'

Theory: Based on 'check' of the given linear code, the procedure constructs the corresponding ideal that gives an opportunity to compute unknown syndrome of the received word y. After computing the unknown syndromes one is able to solve the decoding problem. For basics of the method [Section C.8.5 \[Decoding method based on quadratic equations\]](#), page 790.

Example:

```
LIB "decodegb.lib";
intvec v = option(get);
//correct 2 errors in [7,3] 8-ary code RS code
int t=2; int q=8; int n=7; int redun=4;
ring r=(q,a),x,dp;
matrix h_full=genMDSMat(n,a);
matrix h=submat(h_full,1..redun,1..n);
matrix g=dual_code(h);
matrix x[1][3]=0,0,1,0;
matrix y[1][7]=encode(x,g);
//disturb with 2 errors
matrix rec[1][7]=errorInsert(y,list(2,4),list(1,a));
//generate the system
def A=sysQE(h,rec,t);
setring A;
print(qe);
⇨ U(1)+a^3,
⇨ U(2)+a^2,
⇨ U(3)+a^6,
⇨ U(4),
⇨ V(1)*U(1)+V(2)*U(2)+U(3),
⇨ V(1)*U(2)+V(2)*U(3)+U(4),
⇨ V(1)*U(3)+V(2)*U(4)+U(5),
⇨ V(1)*U(4)+V(2)*U(5)+U(6),
⇨ V(1)*U(5)+V(2)*U(6)+U(7),
⇨ V(1)*U(6)+V(2)*U(7)+U(1),
⇨ V(2)*U(1)+V(1)*U(7)+U(2)
//let us decode
option(redSB);
ideal sys_qe=std(qe);
print(sys_qe);
⇨ U(7)+a,
⇨ U(6)+a^3,
⇨ U(5)+a^3,
⇨ U(4),
⇨ U(3)+a^6,
⇨ U(2)+a^2,
⇨ U(1)+a^3,
```

```

    ↦ V(2)+1,
    ↦ V(1)+a^4
    option(set,v);

```

See also: [Section D.10.2.17 \[sysFL\], page 1964](#).

D.10.2.8 errorInsert

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\], page 1941](#)).

Usage: `errorInsert(y,pos,val)`; `y` is matrix, `pos,val` are list of int's

- `y` is a (code) word,
- `pos` = positions where errors occurred,
- `val` = their corresponding values

Return: corresponding received word

Example:

```

LIB "decodegb.lib";
//correct 2 errors in [7,3] 8-ary code RS code
int t=2; int q=8; int n=7; int redun=4;
ring r=(q,a),x,dp;
matrix h_full=genMDSMat(n,a);
matrix h=submat(h_full,1..redun,1..n);
matrix g=dual_code(h);
matrix x[1][3]=0,0,1,0;
matrix y[1][7]=encode(x,g);
print(y);
    ↦ a6,a6,a3,a,0,0,1
//disturb with 2 errors
matrix rec[1][7]=errorInsert(y,list(2,4),list(1,a));
print(rec);
    ↦ a6,a2,a3,0,0,0,1
print(rec-y);
    ↦ 0,1,0,a,0,0,0

```

D.10.2.9 errorRand

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\], page 1941](#)).

Usage: `errorRand(y, num, e)`; `y` is matrix, `num,e` are int

- `y` is a (code) word,
- `num` is the number of errors,
- `e` is an extension degree (if one wants values to be from $\text{GF}(p^e)$)

Return: corresponding received word

Example:

```

LIB "decodegb.lib";
//correct 2 errors in [7,3] 8-ary code RS code
int t=2; int q=8; int n=7; int redun=4;
ring r=(q,a),x,dp;
matrix h_full=genMDSMat(n,a);
matrix h=submat(h_full,1..redun,1..n);
matrix g=dual_code(h);
matrix x[1][3]=0,0,1,0;

```

```

matrix y[1][7]=encode(x,g);
//disturb with 2 random errors
matrix rec[1][7]=errorRand(y,2,3);
print(rec);
↳ a3,a6,a2,a,0,0,1
print(rec-y);
↳ a4,0,a5,0,0,0,0

```

D.10.2.10 randomCheck

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\], page 1941](#)).

Usage: `randomCheck(m, n, e);` `m,n,e` are int
 - `m x n` are dimensions of the matrix,
 - `e` is an extension degree (if one wants values to be from $\text{GF}(p^e)$)

Return: random check matrix

Example:

```

LIB "decodegb.lib";
int redun=5; int n=15;
ring r=2,x,dp;
//generate random check matrix for a [15,5] binary code
matrix h=randomCheck(redun,n,1);
print(h);
↳ 0,1,0,0,0,1,1,1,0,1,1,0,0,0,0,
↳ 1,1,0,0,0,0,0,1,0,0,0,1,0,0,0,
↳ 1,0,1,1,1,1,0,0,0,1,0,0,1,0,0,
↳ 1,1,0,1,1,0,0,0,0,1,0,0,0,1,0,
↳ 0,1,0,0,0,0,0,1,1,0,0,0,0,0,1
//corresponding generator matrix
matrix g=dual_code(h);
print(g);
↳ 0,0,0,1,1,0,0,0,0,0,0,0,0,0,0,
↳ 0,0,1,0,0,1,1,0,0,0,0,0,0,0,0,
↳ 0,1,1,1,0,0,0,1,0,0,0,0,0,0,0,
↳ 1,1,0,0,0,1,0,0,1,0,0,0,0,0,0,
↳ 0,0,1,1,0,1,0,0,0,1,0,0,0,0,0,
↳ 0,0,1,0,0,1,0,0,0,0,1,0,0,0,0,
↳ 1,0,0,1,0,0,0,0,0,0,0,1,0,0,0,
↳ 0,0,1,0,0,0,0,0,0,0,0,1,0,0,
↳ 0,0,1,1,0,0,0,0,0,0,0,0,1,0,
↳ 1,1,0,0,0,1,0,0,0,0,0,0,0,1

```

D.10.2.11 genMDSMat

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\], page 1941](#)).

Usage: `genMDSMat(n, a);` `n` is int, `a` is number
 - `n x n` are dimensions of the MDS matrix,
 - `a` is a primitive element of the field.

Note: An MDS matrix is constructed in the following way. We take '`a`' to be a generator of the multiplicative group of the field. Then we construct the Vandermonde matrix with this '`a`'.

Assume: extension field should already be defined

Return: a matrix with the MDS property.

Example:

```
LIB "decodegb.lib";
int q=16; int n=15;
ring r=(q,a),x,dp;
//generate an MDS (Vandermonde) matrix
matrix h_full=genMDSMat(n,a);
print(h_full);
⇒ 1,1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
⇒ 1,a, a2, a3, a4, a5, a6, a7, a8, a9, a10,a11,a12,a13,a14,
⇒ 1,a2, a4, a6, a8, a10,a12,a14,a, a3, a5, a7, a9, a11,a13,
⇒ 1,a3, a6, a9, a12,1, a3, a6, a9, a12,1, a3, a6, a9, a12,
⇒ 1,a4, a8, a12,a, a5, a9, a13,a2, a6, a10,a14,a3, a7, a11,
⇒ 1,a5, a10,1, a5, a10,1, a5, a10,1, a5, a10,1, a5, a10,
⇒ 1,a6, a12,a3, a9, 1, a6, a12,a3, a9, 1, a6, a12,a3, a9,
⇒ 1,a7, a14,a6, a13,a5, a12,a4, a11,a3, a10,a2, a9, a, a8,
⇒ 1,a8, a, a9, a2, a10,a3, a11,a4, a12,a5, a13,a6, a14,a7,
⇒ 1,a9, a3, a12,a6, 1, a9, a3, a12,a6, 1, a9, a3, a12,a6,
⇒ 1,a10,a5, 1, a10,a5, 1, a10,a5, 1, a10,a5, 1, a10,a5,
⇒ 1,a11,a7, a3, a14,a10,a6, a2, a13,a9, a5, a, a12,a8, a4,
⇒ 1,a12,a9, a6, a3, 1, a12,a9, a6, a3, 1, a12,a9, a6, a3,
⇒ 1,a13,a11,a9, a7, a5, a3, a, a14,a12,a10,a8, a6, a4, a2,
⇒ 1,a14,a13,a12,a11,a10,a9, a8, a7, a6, a5, a4, a3, a2, a
```

See also: [Section C.8.5 \[Decoding method based on quadratic equations\]](#), page 790.

D.10.2.12 mindist

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\]](#), page 1941).

Usage: mindist (check, q); check matrix, q int

- check is a check matrix,
- q is the field size

Return: minimum distance of the code

Example:

```
LIB "decodegb.lib";
//determine a minimum distance for a [7,3] binary code
int q=8; int n=7; int redun=4; int t=redun+1;
ring r=(q,a),x,dp;
//generate random check matrix
matrix h=randomCheck(redun,n,1);
print(h);
⇒ 0,1,0,1,0,0,0,
⇒ 0,0,1,0,1,0,0,
⇒ 1,1,0,0,0,1,0,
⇒ 1,1,1,0,0,0,1
int l=mindist(h);
l;
⇒ 3
```

D.10.2.13 decode

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\], page 1941](#)).

Usage: `decode(check, rec, t);` `check`, `rec` matrix, `t` int
 - `check` is the check matrix of the code,
 - `rec` is a received word,
 - `t` is an upper bound for the number of errors one wants to correct

Note: The method described in [Section C.8.5 \[Decoding method based on quadratic equations\], page 790](#) is used for decoding.

Assume: Errors in `rec` should be correctable, otherwise the output is unpredictable

Return: a codeword that is closest to `rec`

Example:

```
LIB "decodegb.lib";
//correct 1 error in [15,7] binary code
int t=1; int q=16; int n=15; int redun=10;
ring r=(q,a),x,dp;
//generate random check matrix
matrix h=randomCheck(redun,n,1);
matrix g=dual_code(h);
matrix x[1][n-redun]=0,0,1,0,1,0,1;
matrix y[1][n]=encode(x,g);
print(y);
⇒ 1,0,1,0,1,0,1,1,1,1,0,0,1,0,1
// find out the minimum distance of the code
list l=mindist(h);
//disturb with errors
"Correct ",(l[1]-1) div 2," errors";
⇒ Correct 1 errors
matrix rec[1][n]=errorRand(y,(l[1]-1) div 2,1);
print(rec);
⇒ 1,0,1,0,1,0,1,1,1,0,0,0,1,0,1
//let us decode
matrix dec_word=decode(h,rec);
print(dec_word);
⇒ 1,0,1,0,1,0,1,1,1,1,0,0,1,0,1
```

D.10.2.14 decodeRandom

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\], page 1941](#)).

Usage: `decodeRandom(redun,q,ncodes,ntrials,[e]);` all parameters int
 - `redun` is a redundancy of a (random) code,
 - `q` is the field size,
 - `ncodes` is the number of random codes to be processed,
 - `ntrials` is the number of received vectors per code to be corrected
 - If `e` is given it sets the correction capacity explicitly. It
 should be used in case one expects some lower bound,
 otherwise the procedure tries to compute the real minimum distance
 to find out the error-correction capacity

Return: nothing;

```
LIB "decodegb.lib";
int q=32; int n=25; int redun=n-11; int t=redun+1;
ring r=(q,a),x,dp;
// correct 2 errors in 2 random binary codes, 3 trials each
decodeRandom(n,redun,2,3,2);
⇒ check matrix:
⇒ 0,1,0,0,0,1,1,1,0,1,1,1,0,0,0,0,0,0,0,0,0,0,0,0,
⇒ 1,0,0,0,0,0,1,0,0,1,0,0,1,0,0,0,0,0,0,0,0,0,0,0,
⇒ 1,1,1,1,0,0,0,1,1,1,0,0,0,1,0,0,0,0,0,0,0,0,0,0,

D.10.2.15 decodeCode

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\]](#), page 1941).

Usage: `decodeCode(check, ntrials, [e]);` check matrix, ntrials, e int

- check is a parity check matrix for the code,
- ntrials is the number of received vectors per code to be corrected.
- If e is given it sets the correction capacity explicitly. It should be used in case one expects some lower bound, otherwise the procedure tries to compute the real minimum distance to find out the error-correction capacity

Return: nothing;

Example:

```

LIB "decodegb.lib";
int q=32; int n=25; int redun=n-11; int t=redun+1;
ring r=(q,a),x,dp;
matrix check=randomCheck(redun,n,1);
// correct 2 errors in using the code above, 3 trials
decodeCode(check,3,2);
⇒ check matrix:

D.10.2.16 vanishId

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\]](#), page 1941).

Usage: `vanishId (points);` point is a list of matrices
 'points' is a list of points for which the vanishing ideal is to be constructed

Return: Vanishing ideal corresponding to the given set of points

Example:

```
LIB "decodegb.lib";
ring r=3,(x(1..3)),dp;
//generate all 3-vectors over GF(3)
list points=pointsGen(3,1);
list points2=convPoints(points);
//grasps the first 11 points
list p=graspList(points2,1,11);
print(p);
⇒ [1]:
⇒   _[1,1]=0
⇒   _[2,1]=0
⇒   _[3,1]=0
⇒ [2]:
⇒   _[1,1]=0
⇒   _[2,1]=0
⇒   _[3,1]=1
⇒ [3]:
⇒   _[1,1]=0
⇒   _[2,1]=0
⇒   _[3,1]=-1
⇒ [4]:
⇒   _[1,1]=0
⇒   _[2,1]=1
⇒   _[3,1]=0

⇒   _[1,1]=0
⇒   _[2,1]=1
⇒   _[3,1]=1
⇒ [6]:
⇒   _[1,1]=0
⇒   _[2,1]=1
⇒   _[3,1]=-1
⇒ [7]:
⇒   _[1,1]=0
⇒   _[2,1]=-1
⇒   _[3,1]=0
⇒ [8]:
⇒   _[1,1]=0
⇒   _[2,1]=-1
⇒   _[3,1]=1
⇒ [9]:
⇒   _[1,1]=0
⇒   _[2,1]=-1
⇒   _[3,1]=-1
⇒ [10]:
⇒   _[1,1]=1
⇒   _[2,1]=0
⇒   _[3,1]=0
⇒ [11]:
⇒   _[1,1]=1
```

```

⇒      _[2,1]=0
⇒      _[3,1]=1
//construct the vanishing ideal
ideal id=vanishId(p);
print(id);
⇒ x(1)*x(2),
⇒ x(1)^2-x(1),
⇒ x(3)^3-x(3),
⇒ x(1)*x(3)^2-x(1)*x(3),
⇒ x(2)^3-x(2)

```

D.10.2.17 sysFL

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\]](#), page 1941).

Usage: `sysFL (check,y,t,e,s);` `check,y` matrix, `t,e,s` int

- `check` is a parity check matrix of the code,
- `y` is a received word,
- `t` the number of errors to correct,
- `e` is the extension degree,
- `s` is the dimension of the point for the vanishing ideal

Return: the system of Fitzgerald-Lax for the given decoding problem

Theory: Based on 'check' of the given linear code, the procedure constructs the corresponding ideal constructed with a generalization of Cooper's philosophy. For basics of the method [Section C.8.4 \[Fitzgerald-Lax method\]](#), page 789.

Example:

```

LIB "decodegb.lib";
intvec vopt = option(get);
list l=FLpreprocess(3,1,11,2,"");
def r=l[1];
setring r;
int s_work=l[2];
//the check matrix of [11,6,5] ternary code
matrix h[5][11]=1,0,0,0,0,0,1,1,1,-1,-1,0,
0,1,0,0,0,1,1,-1,1,0,-1,
0,0,1,0,0,1,-1,1,0,1,-1,
0,0,0,1,0,1,-1,0,1,-1,1,
0,0,0,0,1,1,0,-1,-1,1,1;
matrix g=dual_code(h);
matrix x[1][6];
matrix y[1][11]=encode(x,g);
//disturb with 2 errors
matrix rec[1][11]=errorInsert(y,list(2,4),list(1,-1));
//the Fitzgerald-Lax system
ideal sys=sysFL(h,rec,2,1,s_work);
print(sys);
⇒ x1(3)^3-x1(3),
⇒ x1(2)^3-x1(2),
⇒ x1(3)^2*x1(1)-x1(3)*x1(1),
⇒ x1(2)*x1(1),

D.10.2.18 decodeRandomFL

Procedure from library `decodegb.lib` (see [Section D.10.2 \[decodegb.lib\]](#), page 1941).

Usage: `decodeRandomFL(redun,p,e,n,t,ncodes,ntrials,minpol);`

- n is length of codes generated,
- redun = redundancy of codes generated,
- p is the characteristic,
- e is the extension degree,
- t is the number of errors to correct,

- ncodes is the number of random codes to be processed,
- ntrials is the number of received vectors per code to be corrected,
- minpol: due to some peculiarities of SINGULAR one needs to provide minimal polynomial for the extension explicitly

Return: nothing

Example:

```
LIB "decodegb.lib";
// correcting one error for one random binary code of length 25,
// redundancy 14; 10 words are processed
decodeRandomFL(25,14,2,1,1,1,10,"");
⇒ Codeword:
⇒ 1,0,0,1,0,1,0,1,1,1,0,1,0,1,0,0,1,0,1,0,0,1,1,1,0

D.11 System and Control theory

D.11.1 Control theory background

Control systems are usually described by differential (or difference) equations, but their properties of interest are most naturally expressed in terms of the system trajectories (the set of all solutions to the equations). This is formalized by the notion of the system *behavior*. On the other hand, the manipulation of linear system equations can be formalized using algebra, more precisely module theory. The relationship between modules and behaviors is very rich and leads to deep results on system structure.

The key to the module-behavior correspondence is a property of some signal spaces that are modules over the ring of differential (or difference) operators, namely, *the injective cogenerator property*. This property makes it possible to translate any statement on the solution spaces that can be expressed in terms of images and kernels, to an equivalent statement on the modules. Thus analytic properties can be identified with algebraic properties, and conversely, the results of manipulating the modules using computer algebra can be re-translated and interpreted using the language of systems theory. This duality (*algebraic analysis*) is widely used in behavioral systems and control theory today.

For instance, a system is **controllable** (a fundamental property for any control system) if and only if the associated module is torsion-free. This concept can be refined by the so-called controllability degrees. The strongest form of controllability (*flatness*) corresponds to a projective (or even free) module.

Controllability means that one can switch from one system trajectory to another without violating the system law (concatenation of trajectories). For one-dimensional systems (ODE) that evolve in time, this is usually interpreted as switching from a given past trajectory to a desired future trajectory. Thus the system can be forced to behave in an arbitrarily prescribed way.

The extreme case opposed to controllability is **autonomy**: autonomous systems evolve independently according to their law, without being influenceable from the outside. Again, the property can be refined in terms of autonomy degrees.

D.11.2 control.lib

Library: control.lib

Purpose: Algebraic analysis tools for System and Control Theory

Authors: Oleksandr Iena, yena@mathematik.uni-kl.de
 Markus Becker, mbecker@mathematik.uni-kl.de
 Viktor Levandovskyy, levandov@mathematik.uni-kl.de

Support: Forschungsschwerpunkt 'Mathematik und Praxis' (Project of Dr. E. Zerz and V. Levandovskyy), University of Kaiserslautern

Procedures:

D.11.2.1 control

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\]](#), page 1970).

Usage: `control(R)`; R a module (R is the matrix of the system of equations to be investigated)

Return: list

Purpose: compute the list of all the properties concerning controllability of the system (behavior), represented by the matrix R

Note: the properties and corresponding data like controllability, flatness, dimension of the system, degree of controllability, kernel and image representations, genericity of parameters, obstructions to controllability, annihilator of torsion submodule and left inverse are investigated

Example:

```
LIB "control.lib";
// a WindTunnel example
ring A = (0,a, omega, zeta, k),(D1, delta),dp;
module R;
R = [D1+a, -k*a*delta, 0, 0],
    [0, D1, -1, 0],
    [0, omega^2, D1+2*zeta*omega, -omega^2];
R=transpose(R);
view(R);
⇒ D1+(a),(-a*k)*delta,0,0,
⇒ 0,D1,-1,0,
⇒ 0,(omega^2),D1+(2*omega*zeta),(-omega^2)
view(control(R));
⇒ number of first nonzero Ext:
⇒
⇒ 2
⇒
⇒ controllable, not reflexive, image representation:
⇒
⇒ (a*omega^2*k)*delta,
⇒ (omega^2)*D1+(a*omega^2),
⇒ (omega^2)*D1^2+(a*omega^2)*D1,
⇒ D1^3+(a+2*omega*zeta)*D1^2+(2*a*omega*zeta+omega^2)*D1+(a*omega^2)
⇒
⇒ dimension of the system:
⇒
⇒ 2
⇒
⇒ Parameter constellations which might lead to a non-controllable system:
⇒
```

```

    ↪ a,k,omega
    ↪
    ↪

```

D.11.2.2 controlDim

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\], page 1970](#)).

Usage: `controlDim(R)`; R a module (R is the matrix of the system of equations to be investigated)

Return: list

Purpose: computes list of all the properties concerning controllability of the system (behavior), represented by the matrix R

Note: the properties and corresponding data like controllability, flatness, dimension of the system, degree of controllability, kernel and image representations, genericity of parameters, obstructions to controllability, annihilator of torsion submodule and left inverse are investigated.

This procedure is analogous to 'control' but uses dimension calculations.

The implemented approach works for full row rank matrices only (the check is done automatically).

Example:

```

LIB "control.lib";
//a WindTunnel example
ring A = (0,a, omega, zeta, k),(D1, delta),dp;
module R;
R = [D1+a, -k*a*delta, 0, 0],
    [0, D1, -1, 0],
    [0, omega^2, D1+2*zeta*omega, -omega^2];
R=transpose(R);
view(R);
↪ D1+(a),(-a*k)*delta,0,0,
↪ 0,D1,-1,0,
↪ 0,(omega^2),D1+(2*omega*zeta),(-omega^2)
view(controlDim(R));
↪ number of first nonzero Ext:
↪
↪ 2
↪
↪ controllable, not reflexive, image representation:
↪
↪ (a*omega^2*k)*delta,
↪ (omega^2)*D1+(a*omega^2),
↪ (omega^2)*D1^2+(a*omega^2)*D1,
↪ D1^3+(a+2*omega*zeta)*D1^2+(2*a*omega*zeta+omega^2)*D1+(a*omega^2)
↪
↪ dimension of the system:
↪
↪ 2
↪
↪ Parameter constellations which might lead to a non-controllable system:
↪

```

```

    ↪ a,k,omega
    ↪
    ↪

```

D.11.2.3 autonom

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\], page 1970](#)).

Usage: `autonom(R)`; R a module (R is a matrix of the system of equations which is to be investigated)

Return: list

Purpose: find all the properties concerning autonomy of the system (behavior) represented by the matrix R

Note: the properties and corresponding data like autonomy resp. strong autonomy, dimension of the system, autonomy degree, kernel representation and (over)determinacy are investigated

Example:

```

LIB "control.lib";
// Cauchy
ring r=0,(s1,s2,s3,s4),dp;
module R= [s1,-s2],
[s2, s1],
[s3,-s4],
[s4, s3];
R=transpose(R);
view( R );
↪ s1,-s2,
↪ s2,s1 ,
↪ s3,-s4,
↪ s4,s3
view( autonom(R) );
↪ number of first nonzero Ext:
↪
↪ 2
↪
↪ overdetermined, not strongly autonomous
↪
↪ dimension of the system:
↪
↪ 2
↪

```

D.11.2.4 autonomDim

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\], page 1970](#)).

Usage: `autonomDim(R)`; R a module (R is a matrix of the system of equations which is to be investigated)

Return: list

Purpose: computes the list of all the properties concerning autonomy of the system (behavior), represented by the matrix R

Note: the properties and corresponding data like autonomy resp. strong autonomy, dimension of the system, autonomy degree, kernel representation and (over)determinacy are investigated.

This procedure is analogous to 'autonom' but uses dimension calculations

Example:

```
LIB "control.lib";
// Cauchy1 example
ring r=0,(s1,s2,s3,s4),dp;
module R= [s1,-s2],
[s2, s1],
[s3,-s4],
[s4, s3];
R=transpose(R);
view( R );
↳ s1,-s2,
↳ s2,s1 ,
↳ s3,-s4,
↳ s4,s3
view( autonomDim(R) );
↳ number of first nonzero Ext:
↳
↳ 2
↳
↳ overdetermined, not strongly autonomous
↳
↳ dimension of the system:
↳
↳ 2
↳
```

D.11.2.5 leftKernel

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\]](#), page 1970).

Usage: `leftKernel(M)`; M a matrix

Return: module

Purpose: computes left kernel of matrix M (a module of all elements v such that $vM=0$)

Example:

```
LIB "control.lib";
ring r= 0,(x,y,z),dp;
matrix M[3][1] = x,y,z;
print(M);
↳ x,
↳ y,
↳ z
matrix L = leftKernel(M);
print(L);
↳ 0, -z,y,
↳ -y,x, 0,
↳ -z,0, x
// check:
```

```

print(L*M);
↪ 0,
↪ 0,
↪ 0

```

D.11.2.6 rightKernel

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\], page 1970](#)).

Usage: `rightKernel(M)`; M a matrix

Return: module

Purpose: computes the right kernel of matrix M (a module of all elements v such that $Mv=0$)

Example:

```

LIB "control.lib";
ring r = 0,(x,y,z),dp;
matrix M[1][3] = x,y,z;
print(M);
↪ x,y,z
matrix R = rightKernel(M);
print(R);
↪ 0, -y,-z,
↪ -z,x, 0,
↪ y, 0, x
// check:
print(M*R);
↪ 0,0,0

```

D.11.2.7 leftInverse

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\], page 1970](#)).

Usage: `leftInverse(M)`; M a module

Return: module

Purpose: computes such a matrix L, that $LM = \text{Id}$;

Note: exists only in the case when M is free submodule

Example:

```

LIB "control.lib";
// a trivial example:
ring r = 0,(x,z),dp;
matrix M[2][1] = 1,x2z;
print(M);
↪ 1,
↪ x2z
print( leftInverse(M) );
↪ 1,0
kill r;
// derived from the example TwoPendula:
ring r=(0,m1,m2,M,g,L1,L2),Dt,dp;
matrix U[3][1];
U[1,1]=(-L2)*Dt^4+(g)*Dt^2;

```

```

U[2,1]=(-L1)*Dt^4+(g)*Dt^2;
U[3,1]=(L1*L2)*Dt^4+(-g*L1-g*L2)*Dt^2+(g^2);
module M = module(U);
module L = leftInverse(M);
print(L);
↪ (L1^2)/(g^2*L1-g^2*L2), (-L2^2)/(g^2*L1-g^2*L2), 1/(g^2)
// check
print(matrix(L)*matrix(M));
↪ 1

```

D.11.2.8 rightInverse

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\], page 1970](#)).

Usage: `rightInverse(M)`; M a module

Return: module

Purpose: computes such a matrix L, that $ML = \text{Id}$

Note: exists only in the case when M is free submodule

Example:

```

LIB "control.lib";
// a trivial example:
ring r = 0,(x,z),dp;
matrix M[1][2] = 1,x2+z;
print(M);
↪ 1,x2+z
print( rightInverse(M) );
↪ 1,
↪ 0
kill r;
// derived from the TwoPendula example:
ring r=(0,m1,m2,M,g,L1,L2),Dt,dp;
matrix U[1][3];
U[1,1]=(-L2)*Dt^4+(g)*Dt^2;
U[1,2]=(-L1)*Dt^4+(g)*Dt^2;
U[1,3]=(L1*L2)*Dt^4+(-g*L1-g*L2)*Dt^2+(g^2);
module M = module(U);
module L = rightInverse(M);
print(L);
↪ (L1^2)/(g^2*L1-g^2*L2),
↪ (-L2^2)/(g^2*L1-g^2*L2),
↪ 1/(g^2)
// check
print(matrix(M)*matrix(L));
↪ 1

```

D.11.2.9 colrank

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\], page 1970](#)).

Usage: `colrank(M)`; M a matrix/module

Return: int

Purpose: compute the column rank of M as of matrix

Note: this procedure uses Bareiss algorithm

Example:

```
LIB "control.lib";
// de Rham complex
ring r=0,(D(1..3)),dp;
module R;
R=[0,-D(3),D(2)],
[D(3),0,-D(1)],
[-D(2),D(1),0];
R=transpose(R);
colrank(R);
↪ 2
```

D.11.2.10 genericity

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\], page 1970](#)).

Usage: genericity(M); M is a matrix/module

Return: list (of strings)

Purpose: determine parametric expressions which have been assumed to be non-zero in the process of computing the Groebner basis

Note: the output list consists of strings. The first string contains the variables only, whereas each further string contains a single polynomial in parameters.

We strongly recommend to switch on the `redSB` and `redTail` options.

The procedure is effective with the lift procedure for modules with parameters

Example:

```
LIB "control.lib";
// TwoPendula
ring r=(0,m1,m2,M,g,L1,L2),Dt,dp;
module RR =
[m1*L1*Dt^2, m2*L2*Dt^2, -1, (M+m1+m2)*Dt^2],
[m1*L1^2*Dt^2-m1*L1*g, 0, 0, m1*L1*Dt^2],
[0, m2*L2^2*Dt^2-m2*L2*g, 0, m2*L2*Dt^2];
module R = transpose(RR);
module SR = std(R);
matrix T = lift(R,SR);
genericity(T);
↪ [1]:
↪ m1,g,L1,L2
↪ [2]:
↪ L1-L2
/-- The result might be different when computing reduced bases:
matrix T2;
option(redSB);
option(redTail);
module SR2 = std(R);
T2 = lift(R,SR2);
genericity(T2);
↪ [1]:
```

```

⇒ m1,g,L1,m2,L2
⇒ [2]:
⇒ L1-L2

```

D.11.2.11 canonize

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\], page 1970](#)).

Usage: `canonize(L)`; L a list

Return: list

Purpose: modules in the list are canonized by computing their reduced minimal (= unique up to constant factor w.r.t. the given ordering) Groebner bases

Assume: L is the output of `control/autonomy` procedures

Example:

```

LIB "control.lib";
// TwoPendula with L1=L2=L
ring r=(0,m1,m2,M,g,L),Dt,dp;
module RR =
[m1*L*Dt^2, m2*L*Dt^2, -1, (M+m1+m2)*Dt^2],
[m1*L^2*Dt^2-m1*L*g, 0, 0, m1*L*Dt^2],
[0, m2*L^2*Dt^2-m2*L*g, 0, m2*L*Dt^2];
module R = transpose(RR);
list C = control(R);
list CC = canonize(C);
view(CC);
⇒ number of first nonzero Ext:
⇒
⇒ 1
⇒
⇒ not controllable , image representation for controllable part:
⇒
⇒ -Dt^2
⇒ -Dt^2
⇒ (M*L)*Dt^4+(-m1*g-m2*g-M*g)*Dt^2,
⇒ (L)*Dt^2+(-g)
⇒
⇒ kernel representation for controllable part:
⇒
⇒ 1,0,0,
⇒ 0,1,0,
⇒ 0,0,1
⇒
⇒ obstruction to controllability
⇒
⇒ 1,0,0
⇒ 0,1,0
⇒ 0,0,(L)*Dt^2+(-g)
⇒
⇒ annihilator of torsion module (of obstruction to controllability)
⇒
⇒ (L)*Dt^2+(-g)

```

```

↳
↳ dimension of the system:
↳
↳ 1
↳

```

D.11.2.12 iostruct

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\], page 1970](#)).

Usage: `iostruct(R);` R a module

Return: list L with entries: string s, intvec v, module P and module Q

Purpose: if R is the kernel-representation-matrix of some system, then we output a input-ouput representation $P_y = Q_u$ of the system, the components that have been chosen as outputs(intvec v) and a comment s

Note: the procedure uses Bareiss algorithm

Example:

```

LIB "control.lib";
//Example Antenna
ring r = (0, K1, K2, Te, Kp, Kc), (Dt, delta), (c, dp);
module RR;
RR =
[ Dt, -K1, 0, 0, 0, 0, 0, 0, 0 ],
[ 0, Dt+K2/Te, 0, 0, 0, 0, -Kp/Te*delta, -Kc/Te*delta, -Kc/Te*delta ],
[ 0, 0, Dt, -K1, 0, 0, 0, 0, 0 ],
[ 0, 0, 0, Dt+K2/Te, 0, 0, -Kc/Te*delta, -Kp/Te*delta, -Kc/Te*delta ],
[ 0, 0, 0, 0, Dt, -K1, 0, 0, 0 ],
[ 0, 0, 0, 0, 0, Dt+K2/Te, -Kc/Te*delta, -Kc/Te*delta, -Kp/Te*delta ];
module R = transpose(RR);
view(iostruct(R));
↳ The following components have been chosen as outputs:
↳
↳ 1,
↳ 2,
↳ 3,
↳ 4,
↳ 5,
↳ 6
↳
↳ Dt, (-K1)      , 0 , 0      , 0 , 0      ,
↳ 0 , Dt+(K2)/(Te), 0 , 0      , 0 , 0      ,
↳ 0 , 0          , Dt, (-K1)   , 0 , 0      ,
↳ 0 , 0          , 0 , Dt+(K2)/(Te), 0 , 0      ,
↳ 0 , 0          , 0 , 0      , Dt, (-K1)   ,
↳ 0 , 0          , 0 , 0      , 0 , Dt+(K2)/(Te)
↳
↳ 0      , 0      , 0      ,
↳ (-Kp)/(Te)*delta, (-Kc)/(Te)*delta, (-Kc)/(Te)*delta,
↳ 0      , 0      , 0      ,
↳ (-Kc)/(Te)*delta, (-Kp)/(Te)*delta, (-Kc)/(Te)*delta,
↳ 0      , 0      , 0      ,

```

```

    ↪ (-Kc)/(Te)*delta,(-Kc)/(Te)*delta,(-Kp)/(Te)*delta
    ↪

```

D.11.2.13 findTorsion

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\], page 1970](#)).

Usage: `findTorsion(R, I)`; R an ideal/matrix/module, I an ideal

Return: module

Purpose: computes the Groebner basis of the submodule of R, annihilated by I

Note: especially helpful, when I is the annihilator of the $t(R)$ - the torsion submodule of R. In this case, the result is the explicit presentation of $t(R)$ as the submodule of R

Example:

```

LIB "control.lib";
// Flexible Rod
ring A = 0,(D1, D2), (c,dp);
module R= [D1, -D1*D2, -1], [2*D1*D2, -D1-D1*D2^2, 0];
module RR = transpose(R);
list L = control(RR);
// here, we have the annihilator:
ideal LAnn = D1; // = L[10]
module Tr = findTorsion(RR,LAnn);
print(RR); // the module itself
↪ D1,      -D1*D2,      -1,
↪ 2*D1*D2, -D1*D2^2-D1, 0
print(Tr); // generators of the torsion submodule
↪ 0,
↪ 1

```

D.11.2.14 controlExample

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\], page 1970](#)).

Usage: `controlExample(s)`; s a string

Return: ring

Purpose: set up an example from the mini database by initializing a ring and a module in a ring

Note: in order to see the list of available examples, execute `controlExample("show")`; To use an example, one has to do the following. Suppose one calls the ring, where the example will be activated, A. Then, by executing `def A = controlExample("Antenna");` and `setring A;`, A will become a basering from the example "Antenna" with the predefined system module R (transposed). After that one can just execute `control(R)`; respectively `autonom(R)`; to perform the control resp. autonomy analysis of R.

Example:

```

LIB "control.lib";
controlExample("show"); // let us see all available examples:
↪ The list of examples:
↪ name: Cauchy1, desc: 1-dimensional Cauchy equation
↪ name: Cauchy2, desc: 2-dimensional Cauchy equation

```

```

⇒ name: Control1, desc: example of a simple noncontrollable system
⇒ name: Control2, desc: example of a simple controllable system
⇒ name: Antenna, desc: antenna
⇒ name: Einstein, desc: Einstein equations in vacuum
⇒ name: FlexibleRod, desc: flexible rod
⇒ name: TwoPendula, desc: two pendula mounted on a cart
⇒ name: WindTunnel, desc: wind tunnel
⇒ name: Zerz1, desc: example from the lecture of Eva Zerz
def B = controlExample("TwoPendula"); // let us set up a particular example
setring B;
print(R);
⇒ (m1*L1)*Dt^2, (m2*L2)*Dt^2, -1,(m1+m2+M)*Dt^2,
⇒ (m1*L1^2)*Dt^2+(-m1*g*L1),0, 0, (m1*L1)*Dt^2,
⇒ 0, (m2*L2^2)*Dt^2+(-m2*g*L2),0, (m2*L2)*Dt^2

```

D.11.2.15 view

Procedure from library `control.lib` (see [Section D.11.2 \[control.lib\]](#), page 1970).

Usage: `view(M)`; `M` is of any type

Return: no return value

Purpose: procedure for (well-) formatted output of modules, matrices, lists of modules, matrices; shows everything even if entries are long

Note: in case of other types(not 'module', 'matrix', 'list') works just as standard 'print' procedure

Example:

```

LIB "control.lib";
ring r;
list L;
matrix M[1][3] = x2+x,y3-y,z5-4z+7;
L[1] = "a matrix:";
L[2] = M;
L[3] = "an ideal:";
L[4] = ideal(M);
view(L);
⇒ a matrix:
⇒
⇒ x2+x,y3-y,z5-4z+7
⇒
⇒ an ideal:
⇒
⇒ x2+x,
⇒ y3-y,
⇒ z5-4z+7
⇒

```

D.11.3 jacobson.lib

Library: `jacobson.lib`

Purpose: Algorithms for Smith and Jacobson Normal Form

Author: Kristina Schindelar, Kristina.Schindelar@math.rwth-aachen.de,
Viktor Levandovskyy, levandov@math.rwth-aachen.de

Overview: We work over a ring R , that is an Euclidean principal ideal domain. If R is commutative, we suppose R to be a polynomial ring in one variable. If R is non-commutative, we suppose R to have two variables, say x and d . We treat then the basering as the Ore localization of R with respect to the mult. closed set $S = K[x]$ without 0. Thus, we treat basering as principal ideal ring with d a polynomial variable and x an invertible one.

Note, that in computations no division by x will actually happen.

Given a rectangular matrix M over R , one can compute unimodular (that is invertible) square matrices U and V , such that $U*M*V=D$ is a diagonal matrix. Depending on the ring, the diagonal entries of D have certain properties.

We call a square matrix D as before 'a weak Jacobson normal form of M '. It is known, that over the first rational Weyl algebra $K(x)\langle d \rangle$, D can be further transformed into a diagonal matrix $(1,1,\dots,1,f,0,\dots,0)$, where f is in $K(x)\langle d \rangle$. We call such a form of D the strong Jacobson normal form. The existence of strong form is not guaranteed if one works with algebra, which is not rational Weyl algebra.

Procedures: See also: [Section D.11.2 \[control_lib\]](#), [page 1970](#).

D.11.3.1 smith

Procedure from library `jacobson.lib` (see [Section D.11.3 \[jacobson_lib\]](#), [page 1981](#)).

Usage: `smith(M[, eng1, eng2]);` M matrix, `eng1` and `eng2` are optional integers

Return: matrix or list of matrices, depending on arguments

Assume: Basing is a commutative polynomial ring in one variable

Purpose: compute the Smith Normal Form of M with (optionally) transformation matrices

Theory: Groebner bases are used for the Smith form like in [2] and [3].

Note: By default, just the Smith normal form of M is returned.
If the optional integer `eng1` is non-zero, the list $\{U,D,V\}$ is returned where $U*M*V = D$ and the diagonal field entries of D are not normalized. The normalization of the latter can be done with the 'divideUnits' procedure. U and V above are square unimodular (invertible) matrices.
Note, that the procedure works for a rectangular matrix M .

The optional integer `eng2` determines the Groebner basis engine:
0 (default) ensures the use of 'slimgb', otherwise 'std' is used.

Display: If `printlevel=1`, progress debug messages will be printed,
if `printlevel>=2`, all the debug messages will be printed.

Example:

```
LIB "jacobson.lib";
ring r = 0,x,Dp;
matrix m[3][2]=x, x^4+x^2+21, x^4+x^2+x, x^3+x, 4*x^2+x, x;
list s=smith(m,1);
print(s[2]); // non-normalized Smith form of m
↳ 21,0,
↳ 0, x,
↳ 0, 0
print(s[1]*m*s[3] - s[2]); // check U*M*V = D
↳ 0,0,
↳ 0,0,
↳ 0,0
list t = divideUnits(s);
print(t[2]); // the Smith form of m
↳ 1,0,
↳ 0,x,
↳ 0,0
```

See also: [Section D.11.3.3 \[divideUnits\], page 1984](#); [Section D.11.3.2 \[jacobson\], page 1983](#).

D.11.3.2 jacobson

Procedure from library `jacobson.lib` (see [Section D.11.3 \[jacobson.lib\], page 1981](#)).

Usage: `jacobson(M, eng)`; M matrix, eng an optional int

Return: list

Assume: Basing is a (non-commutative) ring in two variables.

Purpose: compute a weak Jacobson normal form of M over the basering

Theory: Groebner bases and involutions are used, following [3]

Note: A list L of matrices {U,D,V} is returned. That is $L[1]*M*L[3]=L[2]$,
where L[2] is a diagonal matrix and
L[1], L[3] are square invertible polynomial (unimodular) matrices.
Note, that M can be rectangular.
The optional integer `eng2` determines the Groebner basis engine:
0 (default) ensures the use of 'slimgb', otherwise 'std' is used.

Display: If `printlevel=1`, progress debug messages will be printed,
if `printlevel>=2`, all the debug messages will be printed.

Example:

```
LIB "jacobson.lib";
ring r = 0,(x,d),Dp;
def R = nc_algebra(1,1); setring R; // the 1st Weyl algebra
matrix m[2][2] = d,x,0,d; print(m);
↳ d,x,
↳ 0,d
list J = jacobson(m); // returns a list with 3 entries
print(J[2]); // a Jacobson Form D for m
```

```

⇒ xd2-d,0,
⇒ 0,      1
print(J[1]*m*J[3] - J[2]); // check that U*M*V = D
⇒ 0,0,
⇒ 0,0
/* now, let us do the same for the shift algebra */
ring r2 = 0,(x,s),Dp;
def R2 = nc_algebra(1,s); setring R2; // the 1st shift algebra
matrix m[2][2] = s,x,0,s; print(m); // matrix of the same for as above
⇒ s,x,
⇒ 0,s
list J = jacobson(m);
print(J[2]); // a Jacobson Form D, quite different from above
⇒ xs2+s2,0,
⇒ 0,      x
print(J[1]*m*J[3] - J[2]); // check that U*M*V = D
⇒ 0,0,
⇒ 0,0

```

See also: [Section D.11.3.3 \[divideUnits\], page 1984](#); [Section D.11.3.1 \[smith\], page 1982](#).

D.11.3.3 divideUnits

Procedure from library `jacobson.lib` (see [Section D.11.3 \[jacobson.lib\], page 1981](#)).

Usage: `divideUnits(L); list L`

Return: matrix or list of matrices

Assume: `L` is an output of `smith` or a `jacobson` procedures, that is either `L` contains one rectangular matrix with elements only on the main diagonal or `L` consists of three matrices, where `L[1]` and `L[3]` are square invertible matrices while `L[2]` is a rectangular matrix with elements only on the main diagonal

Purpose: divide out units from the diagonal and reflect this in transformation matrices

Example:

```

LIB "jacobson.lib";
ring R=(0,m,M,L1,L2,m1,m2,g), D, lp; // two pendula example
matrix P[3][4]=m1*L1*D^2,m2*L2*D^2,(M+m1+m2)*D^2,-1,
m1*L1^2*D^2-m1*L1*g,0,m1*L1*D^2,0,0,
m2*L2^2*D^2-m2*L2*g,m2*L2*D^2,0;
list s=smith(P,1); // returns a list with 3 entries
print(s[2]); // a diagonal form, close to the Smith form
⇒ (L1*L2*m2*g^2-L2^2*m2*g^2),0, 0, 0,
⇒ 0, (L2),0, 0,
⇒ 0, 0, (g^2),0
print(s[1]); // U, left transformation matrix
⇒ 0, (-L2*m2)/(L1*m1), 1,
⇒ (-L2),(M*L2+L2*m1)/(L1*m1),1,
⇒ 0, 1/(L1*m1), 0
list t = divideUnits(s);
print(t[2]); // the Smith form of the matrix P
⇒ 1,0,0,0,
⇒ 0,1,0,0,
⇒ 0,0,1,0

```

```

print(t[1]); // U', modified left transformation matrix
⇒ 0, -1/(L1^2*m1*g^2-L1*L2*m1*g^2), 1/(L1*L2*m2*g^2-L2^2*m2*g^2),
⇒ -1, (M+m1)/(L1*m1), 1/(L2),
⇒ 0, 1/(L1*m1*g^2), 0

```

D.11.4 findifs_lib

Library: findifs.lib

Purpose: Tools for the finite difference schemes

Authors: Viktor Levandovskyy, levandov@math.rwth-aachen.de

Overview: We provide the presentation of difference operators in a polynomial, semi-factorized and a nodal form. Running `findifs_example()`; will demonstrate, how we generate finite difference schemes of linear PDEs from given approximations.

Theory: The method we use have been developed by V. Levandovskyy and Bernd Martin. The computation of a finite difference scheme of a given single linear partial differential equation with constant coefficients with a given approximation rules boils down to the computation of a Groebner basis of a submodule of a free module with respect to the ordering, eliminating module components.

Support: SpezialForschungsBereich F1301 of the Austrian FWF

Procedures: See also: [Section D.15.5 \[finitediff_lib\]](#), page 2372; [Section D.9.2 \[latex_lib\]](#), page 1911.

D.11.4.1 findifs_example

Procedure from library `findifs.lib` (see [Section D.11.4 \[findifs_lib\]](#), page 1985).

Usage: `findifs_example()`;

Return: nothing (demo)

Purpose: demonstration of our approach and this library

Example:

```

LIB "findifs.lib";
findifs_example();
⇒ * Equation: u_tt - A^2 u_xx - B^2 u_yy = 0; A,B are constants
⇒ * we employ three central differences
⇒ * the vector we act on is (u_xx, u_yy, u_tt, u)^T
⇒ * Set up the ring:
⇒ ring r = (0,A,B,dt,dx,dy),(Tx,Ty,Tt),(c,dp);
⇒ * Set up the matrix with equation and approximations:
⇒ matrix M[4][4] =
⇒ // direct equation:
⇒ -A^2, -B^2, 1, 0,
⇒ // central difference u_tt
⇒ 0, 0, -dt^2*Tt, (Tt-1)^2,
⇒ // central difference u_xx
⇒ -dx^2*Tx, 0, 0, (Tx-1)^2,
⇒ // central difference u_yy
⇒ 0, -dy^2*Ty, 0, (Ty-1)^2;
⇒ * Print the differential form of equations:
⇒ (-A^2)*Uxx+(-B^2)*Uyy+Utt,
⇒ (-dt^2*Tt)*Utt+(Tt^2-2*Tt+1)*U,

```

```

⇒ (-dx^2*Tx)*Uxx+(Tx^2-2*Tx+1)*U,
⇒ (-dy^2*Ty)*Uyy+(Ty^2-2*Ty+1)*U
⇒ * Perform the elimination of module components:
⇒ module R = transpose(M);
⇒ module S = std(R);
⇒ * See the result of Groebner bases: generators are columns
⇒ print(S);
⇒ 0,      0,      0,      0,      0,      (A^2),
⇒ 0,      0,      0,      (dy^2)*Ty,  S[2,5],  (B^2),
⇒ 0,      (dt^2)*Tt,  S[3,3],0,      (-dx^2)*Tx,-1,
⇒ S[4,1],-Tt^2+2*Tt-1,S[4,3],-Ty^2+2*Ty-1,S[4,5],  0
⇒ * So, only the first column has its nonzero element in the last componen\
t
⇒ * Hence, this polynomial is the scheme
⇒ poly p = S[4,1];
⇒ print(p);
⇒ (A^2*dt^2*dy^2)*Tx^2*Ty*Tt+(B^2*dt^2*dx^2)*Tx*Ty^2*Tt+(-dx^2*dy^2)*Tx*Ty*\
Tt^2+(-2*A^2*dt^2*dy^2-2*B^2*dt^2*dx^2+2*dx^2*dy^2)*Tx*Ty*Tt+(-dx^2*dy^2)\
*Tx*Ty+(B^2*dt^2*dx^2)*Tx*Tt+(A^2*dt^2*dy^2)*Ty*Tt
⇒ * Create the nodal of the scheme in TeX format:
⇒ ideal I = decoef(p,dt);
⇒ difpoly2tex(I,L);
⇒ \frac{1}{\tri t^2}\cdot (u^{n+2}_{j+1,k+1}+(-2) u^{n+1}_{j+1,k+1}+u^{n}\
_{j+1,k+1})+ \frac{-\lambda^2}{\tri x^2}\cdot (u^{n+1}_{j+2,k+1}+\fra\
c{B^2}{\tri x^2}){\lambda^2}{\tri y^2} u^{n+1}_{j+1,k+2}+\frac{-(2\lam\
bda^2)}{\tri y^2}+2B^2}{\tri x^2}){\lambda^2}{\tri y^2} u^{n+1}_{j+1,k\
+1}+\frac{B^2}{\tri x^2}){\lambda^2}{\tri y^2} u^{n+1}_{j+1}+u^{n+1}_{\
j,k+1})
⇒ * Preparations for the semi-factorized form:
⇒ poly pi1 = subst(I[2],B,0);
⇒ poly pi2 = I[2] - pi1;
⇒ * Show the semi-factorized form of the scheme: 1st summand
⇒ factorize(I[1]);
⇒ [1]:
⇒ _[1]=(-dx^2*dy^2)
⇒ _[2]=Tx
⇒ _[3]=Ty
⇒ _[4]=Tt-1
⇒ [2]:
⇒ 1,1,1,2
⇒ * Show the semi-factorized form of the scheme: 2nd summand
⇒ factorize(pi1);
⇒ [1]:
⇒ _[1]=(A^2*dt^2*dy^2)
⇒ _[2]=Ty
⇒ _[3]=Tt
⇒ _[4]=Tx-1
⇒ [2]:
⇒ 1,1,1,2
⇒ * Show the semi-factorized form of the scheme: 3rd summand
⇒ factorize(pi1);
⇒ [1]:
⇒ _[1]=(B^2*dt^2*dx^2)

```

```

↳   _[2]=Tx
↳   _[3]=Tt
↳   _[4]=Ty-1
↳ [2]:
↳   1,1,1,2

```

D.11.4.2 decoef

Procedure from library `findifs.lib` (see [Section D.11.4 \[findifs.lib\], page 1985](#)).

Usage: `decoef(P,n)`; P a poly, n a number

Return: ideal

Purpose: decompose polynomial P into summands with respect to the presence of the number n in the coefficients

Note: n is usually a parameter with no power

Example:

```

LIB "findifs.lib";
" EXAMPLE:";
↳ EXAMPLE:
ring r = (0,dh,dt),(Tx,Tt),dp;
poly P = (4*dh^2-dt)*Tx^3*Tt + dt*dh*Tt^2 + dh*Tt;
decoef(P,dt);
↳ _[1]=(4*dh^2)*Tx^3*Tt+(dh)*Tt
↳ _[2]=(-dt)*Tx^3*Tt+(dh*dt)*Tt^2
decoef(P,dh);
↳ _[1]=(-dt)*Tx^3*Tt
↳ _[2]=(4*dh^2)*Tx^3*Tt+(dh*dt)*Tt^2+(dh)*Tt

```

D.11.4.3 difpoly2tex

Procedure from library `findifs.lib` (see [Section D.11.4 \[findifs.lib\], page 1985](#)).

Usage: `difpoly2tex(S,P[,Q])`; S an ideal, P and optional Q are lists

Return: string

Purpose: present the difference scheme in the nodal form

Assume: ideal S is the result of `decoef` procedure

Note: a list P may be empty or may contain parameters, which will not appear in denominators
an optional list Q represents the part of the scheme, depending on other function, than the major part

Example:

```

LIB "findifs.lib";
ring r = (0,dh,dt,V),(Tx,Tt),dp;
poly M = (4*dh*Tx+dt)^2*(Tt-1) + V*Tt*Tx;
ideal I = decoef(M,dt);
list L; L[1] = V;
difpoly2tex(I,L);
↳ \frac{1}{8}\tri t\cdot (u^{\{n+1\}}_{\{j+2\}}-u^{\{n\}}_{\{j+2\}}+\frac{\nu}{16}\tri h^{\{2\}}\cdot
   u^{\{n+1\}}_{\{j+1\}})+ \frac{1}{16}\tri h\cdot (u^{\{n+1\}}_{\{j+1\}}-u^{\{n\}}_{\{j+1\}}+\frac{\nu}{16}\tri h^{\{2\}}\cdot

```

```

      c{\tri t}{8\tri h} u^{n+1}_{j}+\frac{-\tri t}{8\tri h} u^{n}_{j})
poly G = V*dh^2*(Tt-Tx)^2;
difpoly2tex(I,L,G);
 $\mapsto \frac{1}{8\tri t}\cdot (u^{n+1}_{j+2}-u^{n}_{j+2}+\frac{\nu}{16\tri h^2}\cdot u^{n+1}_{j+1})+\frac{1}{16\tri h}\cdot (u^{n+1}_{j+1}-u^{n}_{j+1}+\frac{c{\tri t}{8\tri h} u^{n+1}_{j}+\frac{-\tri t}{8\tri h} u^{n}_{j})+\frac{\nu}{128\tri t}\cdot (p^{n}_{j+2}+(-2) p^{n+1}_{j+1}+p^{n+2}_{j})$ 

```

D.11.4.4 exp2pt

Procedure from library `findifs.lib` (see [Section D.11.4 \[findifs.lib\]](#), page 1985).

Usage: `exp2pt(P[L]);` P poly, L an optional list of strings

Return: string

Purpose: convert a polynomial M into the TeX format, in nodal form

Assume: coefficients must not be fractional

Note: an optional list L contains a string, which will replace the default value 'u' for the discretized function

Example:

```

LIB "findifs.lib";
" EXAMPLE:";
 $\mapsto$  EXAMPLE:
ring r = (0,dh,dt),(Tx,Tt),dp;
poly M = (4*dh*Tx^2+1)*(Tt-1)^2;
print(exp2pt(M));
 $\mapsto 4\tri h u^{n+2}_{j+2}+(-8\tri h) u^{n+1}_{j+2}+4\tri h u^{n}_{j+2}+u^{n+2}_{j}+(-2) u^{n+1}_{j}+u^{n}_{j}$ 
print(exp2pt(M,"F"));
 $\mapsto 4\tri h F^{n+2}_{j+2}+(-8\tri h) F^{n+1}_{j+2}+4\tri h F^{n}_{j+2}+F^{n+2}_{j}+(-2) F^{n+1}_{j}+F^{n}_{j}$ 

```

D.11.4.5 texcoef

Procedure from library `findifs.lib` (see [Section D.11.4 \[findifs.lib\]](#), page 1985).

Usage: `texcoef(n);` n a number

Return: string

Purpose: converts the number n into TeX format

Note: if n is a polynomial, `texcoef` adds extra brackets and performs some space substitutions

Example:

```

LIB "findifs.lib";
" EXAMPLE:";
 $\mapsto$  EXAMPLE:
ring r = (0,dh,dt),(Tx,Tt),dp;
number n1,n2,n3 = dt/(4*dh^2-dt),(dt+dh)^2, 1/dh;
n1; texcoef(n1);
 $\mapsto (dt)/(4\tri dh^2-dt)$ 
 $\mapsto \frac{\tri t}{4\tri h^2-\tri t}$ 
n2; texcoef(n2);

```

```

↪ (dh^2+2*dh*dt+dt^2)
↪ (\tri h^2+2\tri h\tri t+\tri t^2)
n3; texcoef(n3);
↪ 1/(dh)
↪ \frac{1}{\tri h}

```

D.11.4.6 npar

Procedure from library `findifs.lib` (see [Section D.11.4 \[findifs.lib\], page 1985](#)).

Usage: `npar(n)`; n a number

Return: `int`

Purpose: searches for 'n' among the parameters and returns its number

Example:

```

LIB "findifs.lib";
ring r = (0,dh,dt,theta,A),t,dp;
npar(dh);
↪ 1
number T = theta;
npar(T);
↪ 3
npar(dh^2);
↪ Incorrect parameter
↪ 0

```

D.11.4.7 magnitude

Procedure from library `findifs.lib` (see [Section D.11.4 \[findifs.lib\], page 1985](#)).

Usage: `magnitude(P)`; P a poly

Return: `poly`

Purpose: compute the square of the magnitude of a complex expression

Assume: `i` is the variable of a basering

Example:

```

LIB "findifs.lib";
ring r = (0,d),(g,i,sin,cos),dp;
poly P = d*i*sin - g*cos +d^2*i;
NF( magnitude(P), std(i^2+1) );
↪ g^2*cos^2+(d^2)*sin^2+(2*d^3)*sin+(d^4)

```

D.11.4.8 replace

Procedure from library `findifs.lib` (see [Section D.11.4 \[findifs.lib\], page 1985](#)).

Usage: `replace(s,what,with)`; s,what,with strings

Return: `string`

Purpose: replaces in 's' all the substrings 'what' with substring 'with'

Note:

Example:

```

LIB "findifs.lib";
" EXAMPLE:";
⇨ EXAMPLE:
ring r = (0,dt,theta),Tt,dp;
poly p = (Tt*dt+theta+1)^2+2;
string s = texfactorize("",p);
s;
⇨ $(dt^2)\cdot Tt^2+(2dttheta+2dt)\cdot Tt+(theta^2+2theta+3))$
s = replace(s,"Tt","T_t"); s;
⇨ $(dt^2)\cdot T_t^2+(2dttheta+2dt)\cdot T_t+(theta^2+2theta+3))$
s = replace(s,"dt","\\tri t"); s;
⇨ $(\\tri t^2)\cdot T_t^2+(2\\tri ttheta+2\\tri t)\cdot T_t+(theta^2+2the\
ta+3))$
s = replace(s,"theta","\\theta"); s;
⇨ $(\\tri t^2)\cdot T_t^2+(2\\tri t\\theta+2\\tri t)\cdot T_t+(\\theta^2+2\\
theta+3))$

```

D.11.4.9 xchange

Procedure from library `findifs.lib` (see [Section D.11.4 \[findifs.lib\]](#), page 1985).

Usage: `xchange(w,a,b)`; `w,a,b` strings

Return: string

Purpose: exchanges substring 'a' with a substring 'b' in the string `w`

Note:

Example:

```

LIB "findifs.lib";
" EXAMPLE:";
⇨ EXAMPLE:
ring r = (0,dt,dh,A),Tt,dp;
poly p = (Tt*dt+dh+1)^2+2*A;
string s = texpoly("",p);
s;
⇨ $dt^2\cdot Tt^2+(2dtdh+2dt)\cdot Tt+(dh^2+2dh+2A+1)$
string t = xchange(s,"dh","dt");
t;
⇨ $dh^2\cdot Tt^2+(2dhdt+2dh)\cdot Tt+(dt^2+2dt+2A+1)$

```

D.12 Teaching

The libraries in this section are intended to be used for teaching purposes but not for serious computations.

D.12.1 aksaka.lib

Library: `aksaka.lib`

Purpose: Procedures for primality testing after Agrawal, Saxena, Kayal

Authors: Christoph Mang

Overview: Algorithms for primality testing in polynomial time based on the ideas of Agrawal, Saxena and Kayal.

Procedures:

D.12.1.1 fastExpt

Procedure from library `aksaka.lib` (see [Section D.12.1 \[aksaka.lib\], page 1990](#)).

Usage: `fastExpt(a,m,n)`; $a, m, n = \text{number}$;

Return: the m -th power of a ; if $a^m > n$ the procedure returns $n+1$

Note: uses fast exponentiation

Example:

```
LIB "aksaka.lib";
fastExpt(2,10,1022);
↦ 1023
```

D.12.1.2 log2

Procedure from library `aksaka.lib` (see [Section D.12.1 \[aksaka.lib\], page 1990](#)).

Usage: `log2(x)`;

Return: logarithm to basis 2 of x

Note: calculates the natural logarithm of x with a power-series of the \ln , then the basis is changed to 2

Example:

```
LIB "aksaka.lib";
log2(1024);
↦ 10
```

D.12.1.3 PerfectPowerTest

Procedure from library `aksaka.lib` (see [Section D.12.1 \[aksaka.lib\], page 1990](#)).

Usage: `PerfectPowerTest(n)`;

Return: 0 if there are numbers $a, b > 1$ with $a^b = n$;
 1 if there are no numbers $a, b > 1$ with $a^b = n$;
 if `printlevel` ≥ 1 and there are $a, b > 1$ with $a^b = n$,
 then a, b are printed

Example:

```
LIB "aksaka.lib";
PerfectPowerTest(887503681);
↦ 0
```

D.12.1.4 wurzel

Procedure from library `aksaka.lib` (see [Section D.12.1 \[aksaka.lib\], page 1990](#)).

Usage: `wurzel(r)`;

Assume: characteristic of basering is 0, $r \geq 0$

Return: number, square root of r

Example:

```
LIB "aksaka.lib";
ring R = 0,x,dp;
wurzel(7629412809180100);
↪ 3441627728253432342460123298897595164661535507549430119821503875373993001\
950914732024064729050404203240063089015829737039655/394020061963944792122\
7904010014361380507973927046544666794829340424572177149721061141426625488\
4915640806627990306816
```

D.12.1.5 euler

Procedure from library `aksaka.lib` (see [Section D.12.1 \[aksaka.lib\]](#), page 1990).

Usage: `euler(r);`

Return: `bigint phi(r)`, where `phi` is Eulers phi-function

Note: first `r` is factorized with `proc PollardRho`, then `phi(r)` is calculated with the help of `phi(p)` of every factor `p`;

Example:

```
LIB "aksaka.lib";
euler(99991);
↪ 99990
```

D.12.1.6 coeffmod

Procedure from library `aksaka.lib` (see [Section D.12.1 \[aksaka.lib\]](#), page 1990).

Usage: `coeffmod(f,n);`

Assume: poly `f` depends on at most `var(1)` of the basering

Return: poly `f` modulo number `n`

Note: at first the coefficients of the monomials of the polynomial `f` are determined, then their remainder modulo `n` is calculated, after that the polynomial 'is put together' again

Example:

```
LIB "aksaka.lib";
ring R = 0,x,dp;
poly f=2457*x4+52345*x3-98*x2+5;
bigint n=3;
coeffmod(f,n);
↪ x3+x2+2
```

D.12.1.7 powerpolyX

Procedure from library `aksaka.lib` (see [Section D.12.1 \[aksaka.lib\]](#), page 1990).

Usage: `powerpolyX(q,n,a,r);`

Return: the `q`-th power of poly `a` modulo poly `r` and number `n`

Example:

```
LIB "aksaka.lib";
ring R=0,x,dp;
poly a=3*x3-x2+5;
poly r=x7-1;
```

```

bigint q=123;
bigint n=5;
powerpolyX(q,n,a,r);
↦ 3x5+2x4+x3+x2+1

```

D.12.1.8 ask

Procedure from library `aksaka.lib` (see [Section D.12.1 \[aksaka.lib\]](#), page 1990).

Usage: `ask(n);`

Assume: `n>1`

Return: 0 if `n` is composite;
 1 if `n` is prime;
 if `printlevel` ≥ 1 , you are informed what the procedure will do or has calculated

Note: ASK-algorithm; uses `proc powerpolyX` for step 5

Example:

```

LIB "aksaka.lib";
//ask(100003);
ask(32003);
↦ 1

```

D.12.2 crypto.lib

Library: `crypto.lib`

Purpose: Procedures for teaching cryptography

Authors: Gerhard Pfister, pfister@mathematik.uni-kl.de
 David Brittinger, dativ@gmx.net

Overview: The library contains procedures to compute the discrete logarithm, primality-tests, factorization included elliptic curves. The library is intended to be used for teaching purposes but not for serious computations. Sufficiently high `printlevel` allows to control each step, thus illustrating the algorithms at work.

Procedures:

D.12.2.1 round

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\]](#), page 1993).

Usage: `round(r);`

Return: the nearest number to `r` out of \mathbb{Z}

Assume: `r` should be a rational or a real number

Example:

```

LIB "crypto.lib";
ring R = (real,50),x,dp;
number r=7357683445788723456321.6788643224;
round(r);
↦ 7357683445788723456322

```

D.12.2.2 bubblesort

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `bubblesort(L);`

Return: list L, sort in decreasing order

Example:

```
LIB "crypto.lib";
ring r = 0,x,dp;
list L=-567,-233,446,12,-34,8907;
bubblesort(L);
⇒ [1]:
   8907
⇒ [2]:
   446
⇒ [3]:
   12
⇒ [4]:
  -34
⇒ [5]:
 -233
⇒ [6]:
 -567
```

D.12.2.3 decimal

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `decimal(s); s = string`

Return: the (decimal) number corresponding to the hexadecimal number s

Example:

```
LIB "crypto.lib";
string s ="8edfe37dae96cfd2466d77d3884d4196";
decimal(s);
⇒ 189912871665444375716340628395668619670
```

D.12.2.4 eexgcdN

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `eexgcdN(L);`

Return: list T such that $\sum_i L[i] \cdot T[i] = T[n+1] = \gcd(L[1], \dots, L[n])$

Example:

```
LIB "crypto.lib";
eexgcdN(list(24,15,21));
⇒ [1]:
   2
⇒ [2]:
  -3
⇒ [3]:
   0
⇒ [4]:
   3
```

D.12.2.5 lcmN

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\]](#), page 1993).

Usage: `lcmN(a,b);`

Return: `lcm(a,b);`

Example:

```
LIB "crypto.lib";
lcmN(24,15);
↦ 120
```

D.12.2.6 powerN

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\]](#), page 1993).

Usage: `powerN(m,d,n);`

Return: `m^d mod n`

Example:

```
LIB "crypto.lib";
powerN(24,15,7);
↦ 6
```

D.12.2.7 chineseRem

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\]](#), page 1993).

Usage: `chineseRem(T,L);`

Return: `x` such that `x = T[i] mod L[i]`

Note: chinese remainder theorem

Example:

```
LIB "crypto.lib";
chineseRem(list(24,15,7),list(2,3,5));
↦ 12
```

D.12.2.8 Jacobi

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\]](#), page 1993).

Usage: `Jacobi(a,n);`

Return: the generalized Legendre symbol

Note: if `n` is an odd prime then `Jacobi(a,n)=0,1,-1` if `n|a`, `a=x^2 mod n`, else

Example:

```
LIB "crypto.lib";
Jacobi(13580555397810650806,5792543);
↦ 1
```

D.12.2.9 primList

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `primList(n);`

Return: the list of all primes $\leq n$

Example:

```
LIB "crypto.lib";
list L=primList(100);
size(L);
  ↪ 25
L[size(L)];
  ↪ 97
```

D.12.2.10 primL

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `primL(q);`

Return: list of the first primes p_1, \dots, p_r such that $q > p_1 \dots p_{r-1}$ and $q < p_1 \dots p_r$

Example:

```
LIB "crypto.lib";
primL(20);
  ↪ [1]:
  ↪ 2
  ↪ [2]:
  ↪ 3
  ↪ [3]:
  ↪ 5
```

D.12.2.11 intPart

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `intPart(x);`

Return: the integral part of a rational number

Example:

```
LIB "crypto.lib";
ring r=0,x,dp;
intPart(7/3);
  ↪ 2
```

D.12.2.12 intRoot

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `intRoot(m);`

Return: the integral part of the square root of m

Example:

```
LIB "crypto.lib";
intRoot(20);
  ↪ 4
```

D.12.2.13 squareRoot

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `squareRoot(a,p);`

Return: the square root of a in \mathbb{Z}/p , p prime

Note: assumes the Jacobi symbol is 1 or $p=2$.

Example:

```
LIB "crypto.lib";
squareRoot(8315890421938608,32003);
↦ 18784
```

D.12.2.14 solutionsMod2

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `solutionsMod2(M);`

Return: an intmat containing a basis of the vector space of solutions of the linear system of equations defined by M over the prime field of characteristic 2

Example:

```
LIB "crypto.lib";
bigintmat M[3][3]=1,2,3,4,5,6,7,6,5;
solutionsMod2(M);
↦ 1,0,1
```

D.12.2.15 powerX

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `powerX(q,i,I);`

Return: the q -th power of the i -th variable modulo I

Assume: I is a standard basis

Example:

```
LIB "crypto.lib";
ring R = 0,(x,y),dp;
powerX(100,2,std(ideal(x3-1,y2-x)));
↦ x2
```

D.12.2.16 babyGiant

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `babyGiant(b,y,p);`

Return: the discrete logarithm x : $b^x = y \bmod p$

Note: This procedure works based on Shank's baby step - giant step method.

Example:

```
LIB "crypto.lib";
bigint b=2;
bigint y=10;
bigint p=101;
babyGiant(b,y,p);
↦ 25
```

D.12.2.17 rho

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `rho(b,y,p);`

Return: the discrete logarithm $x = \log_b(y)$: $b^x = y \pmod p$

Note: Pollard's rho:
choose random f_0 in $0, \dots, p-2$, $e_0 = 0$, define $x_0 = b^{f_0}$, define $x_i = y^{e_i} b^{f_i}$ as below.
For i large enough there is i with $x_{(i/2)} = x_i$. Let $s := e_{(i/2)} - e_i \pmod{p-1}$ and $t := f_{(i/2)} - f_i \pmod{p-1}$, $d = \gcd(s, p-1) = u*s + v*(p-1)$ then $x = tu/d + j*(p-1)/d$ for some j (to be found by trying)

Example:

```
LIB "crypto.lib";
bigint b=2;
bigint y=10;
bigint p=101;
rho(b,y,p);
↦ 25
```

D.12.2.18 MillerRabin

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `MillerRabin(n,k);`

Return: 1 if n is prime, 0 else

Note: probabilistic test of Miller-Rabin with k loops to test if n is prime. Using the theorem:
If n is prime, $n-1 = 2^s * r$, r odd, then $\text{powerN}(a, r, n) = 1$ or $\text{powerN}(a, r * 2^i, n) = -1$ for some i

Example:

```
LIB "crypto.lib";
bigint x=2;
x=x^787-1;
MillerRabin(x,3);
↦ 0
```

D.12.2.19 SolowayStrassen

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `SolowayStrassen(n,k);`

Return: 1 if n is prime, 0 else

Note: probabilistic test of Soloway-Strassen with k loops to test if n is prime using the theorem: If n is prime then
 $\text{powerN}(a, (n-1)/2, n) = \text{Jacobi}(a, n) \pmod n$

Example:

```
LIB "crypto.lib";
bigint h=10;
bigint p=h^100+267;
//p=h^100+43723;
```

```
//p=h^200+632347;
SolowayStrassen(h,3);
⇨ 0
```

D.12.2.20 PocklingtonLehmer

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\]](#), page 1993).

Usage: PocklingtonLehmer(N); optional: PocklingtonLehmer(N,L); L a list of the first k primes

Return: message N is not prime or $\{A, \{p\}, \{a_p\}\}$ as certificate for N being prime

Note: assumes that it is possible to factorize $N-1=A*B$ such that $\gcd(A,B)=1$, the factorization of A is completely known and $A^2 > N$.
N is prime if and only if for each prime factor p of A we can find a_p such that $a_p^{(N-1)}$ mod N and $\gcd(a_p^{(N-1)/p}-1, N)=1$

Example:

```
LIB "crypto.lib";
bigint N=105554676553297;
PocklingtonLehmer(N);
⇨ [1]:

⇨ [3]:
```

```

⇒      [1]:
⇒      1048583
⇒      [2]:
⇒      2

```

D.12.2.21 PollardRho

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\]](#), page 1993).

Usage: PollardRho(n,k,allFactors); optional: PollardRho(n,k,allFactors,L); L a list of the first k primes

Return: a list of factors of n (which could be just n), if allFactors=0
a list of all factors of n, if allFactors=1

Note: probabilistic rho-algorithm of Pollard to find a factor of n in k loops. Creates a sequence x_i such that $(x_i)^2 = (x_{2i})^2 \pmod n$ for some i, computes $\gcd(x_i - x_{2i}, n)$ to find a divisor. To define the sequence choose x, a and define $x_{n+1} = x_n^2 + a \pmod n$, $x_1 = x$. If allFactors is 1, it tries to find recursively all prime factors using the Soloway-Strassen test.

Example:

```

LIB "crypto.lib";
bigint h=10;
bigint p=h^30+4;
PollardRho(p,5000,0);
⇒ [1]:
⇒ 2
⇒ [2]:
⇒ 157
⇒ [3]:
⇒ 18737561
⇒ [4]:
⇒ 84982068258408294013

```

See also: [Section 5.1.119 \[primefactors\]](#), page 241.

D.12.2.22 pFactor

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\]](#), page 1993).

Usage: pFactor(n,B,P); n to be factorized, B a bound, P a list of primes

Return: a list of factors of n or n if no factor found

Note: Pollard's p-factorization creates the product k of powers of primes (bounded by B) from the list P with the idea that for a prime divisor p of n we have $p-1 \mid k$, and then p divides $\gcd(a^{k-1}, n)$ for some random a

Example:

```

LIB "crypto.lib";
list L=primList(1000);
pFactor(1241143,13,L);
⇒ 547
bigint h=10;
h=h^30+25;

```

```
pFactor(h,20,L);
↳ 325
```

D.12.2.23 quadraticSieve

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `quadraticSieve(n,c,B,k)`; n to be factorized, $[-c,c]$ the sieve-intervall, B a list of primes, k for using the first k elements in B

Return: a list of factors of n or the message: no divisor found

Note: The idea being used is to find x,y such that $x^2=y^2 \bmod n$ then $\gcd(x-y,n)$ can be a proper divisor of n

Example:

```
LIB "crypto.lib";
list L=primList(5000);
quadraticSieve(7429,3,L,4);
↳ 17
quadraticSieve(1241143,100,L,50);
↳ 547
```

D.12.2.24 isOnCurve

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `isOnCurve(N,a,b,P)`;

Return: 1 or 0 (depending on whether P is on the curve or not)

Note: checks whether $P=(P[1]:P[2]:P[3])$ is a point on the elliptic curve defined by $y^2z=x^3+a*xz^2+b*z^3$ over \mathbb{Z}/N

Example:

```
LIB "crypto.lib";
isOnCurve(32003,5,7,list(10,16,1));
↳ 0
```

D.12.2.25 ellipticAdd

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `ellipticAdd(N,a,b,P,Q)`;

Return: list L , representing the point $P+Q$

Note: $P=(P[1]:P[2]:P[3])$, $Q=(Q[1]:Q[2]:Q[3])$ points on the elliptic curve defined by $y^2z=x^3+a*xz^2+b*z^3$ over \mathbb{Z}/N

Example:

```
LIB "crypto.lib";
bigint N=11;
bigint a=1;
bigint b=6;
list P,Q;
P[1]=2;
P[2]=4;
```

```

P[3]=1;
Q[1]=3;
Q[2]=5;
Q[3]=1;
ellipticAdd(N,a,b,P,Q);
⇒ [1]:
⇒ 7
⇒ [2]:
⇒ 2
⇒ [3]:
⇒ 1

```

D.12.2.26 ellipticMult

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `ellipticMult(N,a,b,P,k);`

Return: a list L representing the point $k \cdot P$

Note: $P=(P[1]:P[2]:P[3])$ a point on the elliptic curve defined by $y^2z=x^3+a*xz^2+b*z^3$ over \mathbb{Z}/N

Example:

```

LIB "crypto.lib";
bigint N=11;
bigint a=1;
bigint b=6;
list P;
P[1]=2;
P[2]=4;
P[3]=1;
ellipticMult(N,a,b,P,3);
⇒ [1]:
⇒ 8
⇒ [2]:
⇒ 8
⇒ [3]:
⇒ 1

```

D.12.2.27 ellipticRandomCurve

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `ellipticRandomCurve(N);`

Return: a list of two random numbers a, b and $4a^3+27b^2 \bmod N$

Note: $y^2z=x^3+a*xz^2+b^2*z^3$ defines an elliptic curve over \mathbb{Z}/N

Example:

```

LIB "crypto.lib";
ellipticRandomCurve(32003);
⇒ [1]:
⇒ 22857
⇒ [2]:
⇒ 24963

```

```

⇒ [3]:
⇒ 1

```

D.12.2.28 ellipticRandomPoint

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `ellipticRandomPoint(N,a,b);`

Return: a list representing a random point $(x:y:z)$ of the elliptic curve defined by $y^2z = x^3 + a*xz^2 + b*z^3$ over \mathbb{Z}/N

Example:

```

LIB "crypto.lib";
ellipticRandomPoint(32003,3,181);
⇒ [1]:
⇒ 22857
⇒ [2]:
⇒ 17476
⇒ [3]:
⇒ 1

```

D.12.2.29 countPoints

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `countPoints(N,a,b);`

Return: the number of points of the elliptic curve defined by $y^2 = x^3 + a*x + b$ over \mathbb{Z}/N

Note: trivial approach

Example:

```

LIB "crypto.lib";
countPoints(181,71,150);
⇒ 198

```

D.12.2.30 ellipticAllPoints

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `ellipticAllPoints(N,a,b);`

Return: list of points $(x:y:z)$ of the elliptic curve defined by $y^2z = x^3 + a*xz^2 + b*z^3$ over \mathbb{Z}/N

Example:

```

LIB "crypto.lib";
list L=ellipticAllPoints(181,71,150);
size(L);
⇒ 198
L[size(L)];
⇒ [1]:
⇒ 179
⇒ [2]:
⇒ 0
⇒ [3]:
⇒ 1

```

D.12.2.31 ShanksMestre

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `ShanksMestre(q,a,b)`; optional: `ShanksMestre(q,a,b,s)`; s the number of loops in the algorithm (default $s=1$)

Return: the number of points of the elliptic curve defined by $y^2=x^3+ax+b$ over \mathbb{Z}/N

Note: algorithm of Shanks and Mestre (baby-step-giant-step)

Example:

```
LIB "crypto.lib";
ShanksMestre(32003,71,602);
↦ 32021
```

D.12.2.32 Schoof

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `Schoof(N,a,b)`;

Return: the number of points of the elliptic curve defined by $y^2=x^3+ax+b$ over \mathbb{Z}/N

Note: algorithm of Schoof

Example:

```
LIB "crypto.lib";
Schoof(32003,71,602);
↦ 32021
```

D.12.2.33 generateG

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `generateG(a,b,m)`;

Return: m -th division polynomial

Note: generate the so-called division polynomials, i.e., the recursively defined polynomials $p_m = \text{generateG}(a,b,m)$ in $\mathbb{Z}[x, y]$ such that, for a point $(x:y:1)$ on the elliptic curve defined by $y^2=x^3+ax+b$ over \mathbb{Z}/N the point

$$m^*P = (x - (p_{-(m-1)} * p_{-(m+1)}) / p_{-m}^2, (p_{-(m+2)} * p_{-(m-1)}^2 - p_{-(m-2)} * p_{-(m+1)}^2) / 4y * p_{-m}^3 : 1) \text{ and } m^*P = 0 \text{ if and only if } p_{-m}(P) = 0$$

Example:

```
LIB "crypto.lib";
ring R = 0,(x,y),dp;
generateG(7,15,4);
↦ 4xy6+140xy4+1200xy3-980xy2-1680xy-8572x
```

D.12.2.34 factorLenstraECM

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `factorLenstraECM(N,S,B)`; optional: `factorLenstraECM(N,S,B,d)`; $d+1$ the number of loops in the algorithm (default $d=0$)

Return: a factor of N or the message no factor found

Note:

- computes a factor of N using Lenstra's ECM factorization
- the idea is that the fact that N is not prime is detected using the operations on the elliptic curve
- is similarly to Pollard's $p-1$ -factorization

Example:

```
LIB "crypto.lib";
list L=primList(1000);
factorLenstraECM(181*32003,L,10,5);
↪ 181
bigint h=10;
h=h^30+25;
factorLenstraECM(h,L,4,3);
↪ 13
```

D.12.2.35 ECPP

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\]](#), page 1993).

Usage: ECPP(N);

Return: message: N is not prime or $\{L, P, m, q\}$ as certificate for N being prime
 L a list ($y^2 = x^3 + L[1]*x + L[2]$ defines an elliptic curve C)
 P a list ($(P[1]:P[2]:P[3])$ is a point of C)
 m, q integers

Assume: $\gcd(N, 6) = 1$

Note: The basis of the algorithm is the following theorem:
 Given C , an elliptic curve over \mathbb{Z}/N , P a point of $C(\mathbb{Z}/N)$, m an integer, q a prime with the following properties:

- $q \mid m$
- $q > (4\text{-th root}(N) + 1)^2$
- $m*P = 0 = (0:1:0)$
- $(m/q)*P = (x:y:z)$ and z a unit in \mathbb{Z}/N

Then N is prime.

Example:

```
LIB "crypto.lib";
bigint N=1267985441;
ECPP(N);
↪ P= [1]:
↪ 780306204
↪ [2]:
↪ 1106324420
↪ [3]:
↪ 1
↪ [1]:
↪ [1]:
↪ 67394594
↪ [2]:
↪ 380636642
↪ [2]:
↪ [1]:
↪ 780306204
```

```

↳ 1267993236
↳ [4]:
↳ 105666103

```

D.12.2.36 calculate_ordering

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `calculate_ordering(num1, primitive, mod1)`

Return: `x` so that $\text{primitive}^x == \text{num1} \bmod \text{mod1}$

Example:

```

LIB "crypto.lib";
bigint mod1 = 33;
bigint primitive = 14;
bigint num1 = 5;
calculate_ordering(num1,primitive,mod1);
↳ 3

```

D.12.2.37 is_primitive_root

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `is_primitive_root(primitive, mod1)`

Return: 1 if `primitive` is a primitive root modulo `mod1`, 0 otherwise

Example:

```

LIB "crypto.lib";
is_primitive_root(3,7);
↳ 1
is_primitive_root(2,7);
↳ 0

```

D.12.2.38 find_first_primitive_root

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `find_first_primitive_root(mod1)`

Return: First primitive root modulo `mod1`, 0 if no root can be found.

Example:

```

LIB "crypto.lib";
ring r = 0,x,lp;
find_first_primitive_root(7);
↳ 3
find_first_primitive_root(557);
↳ 2

```

D.12.2.39 binary_add

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `binary_add(binary_list)`

Return: binary encoded list, increased by 1

Example:

```
LIB "crypto.lib";
ring r = 0,x,lp;
list binary_list = 1,0,1,1,1;
binary_add(binary_list);
↪ [1]:
↪    1
↪ [2]:
↪    1
↪ [3]:
↪    0
↪ [4]:
↪    0
↪ [5]:
↪    0
```

D.12.2.40 inverse_modulus

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `inverse_modulus(num, mod1)`

Return: inverse element of num modulo mod1

Example:

```
LIB "crypto.lib";
ring r = 0,x,lp;
int mod1 = 13;
int num = 5;
inverse_modulus(num,mod1);
↪ 8
```

D.12.2.41 is_prime

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `is_prime(n)`

Return: 1 if n is prime, 0 otherwise

Example:

```
LIB "crypto.lib";
ring r = 0,x,lp;
is_prime(10);
↪ 0
is_prime(7);
↪ 1
```

D.12.2.42 find_index

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `find_index(a, e)`

Return: Returns the list index of element `e` in list `a`. Returns 0 if `e` is not in `a`

Example:

```
LIB "crypto.lib";
list a = 1,5,20,6,37;
find_index(a,20);
⇒ 3
find_index(a,6);
⇒ 4
find_index(a,100);
⇒ 0
```

D.12.2.43 subset_sum01

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `subset_sum01(knapsack,solution)`

Return: binary list of the positions of the elements included in the subset sum or 0 if no solution exists

Note: This will return the first solution of the ssk-problem, given be the smallest binary encoding. It wont return several solutions if they exist

Example:

```
LIB "crypto.lib";
list h=1,4,7,32;
subset_sum01(h,20);
⇒ 0
subset_sum01(h,11);
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 1
⇒ [3]:
⇒ 1
⇒ [4]:
⇒ 0
subset_sum01(h,33);
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 0
⇒ [3]:
⇒ 0
⇒ [4]:
⇒ 1
```

D.12.2.44 subset_sum02

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `subset_sum02(knapsack,sol)`

Return: binary list of the positions of the elements included in the subset sum or 0 if no solution exists

Example:

```
LIB "crypto.lib";
list h=1,4,7,32;
subset_sum02(h,20);
⇒ 0
subset_sum02(h,11);
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 1
⇒ [3]:
⇒ 1
⇒ [4]:
⇒ 0
subset_sum02(h,33);
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 0
⇒ [3]:
⇒ 0
⇒ [4]:
⇒ 1
```

D.12.2.45 unbounded_knapsack

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `unbounded_knapsack(knapsack,profit,capacity)`

Return: list of maximum profit of each iteration. For example, `output_list[2]` contains the maximum profit that can be achieved if the knapsack has capacity 2.

Example:

```
LIB "crypto.lib";
list h=1,4,7,32;
list knapsack = 5,2;
list profit = 10,3;
int capacity = 5;
unbounded_knapsack(knapsack,profit,capacity);
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 0
⇒ [3]:
⇒ 3
⇒ [4]:
```

```

⇒      3
⇒ [5]:
⇒      6
⇒ [6]:
⇒     10

```

D.12.2.46 multidimensional_knapsack

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `multidimensional_knapsack(m, capacities, profits)`

Return: binary list of the positions of the elements included in the optimal selection

Example:

```

LIB "crypto.lib";
ring r = 0,x,lp;
matrix m[3][3] = 1,4,10,7,8,3,1,9,7;
list c = 12,17,10;
list p = 3,2,5;
multidimensional_knapsack(m,c,p);
⇒ [1]:
⇒      1
⇒ [2]:
⇒      0
⇒ [3]:
⇒      1

```

D.12.2.47 naccache_stern_generation

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `naccache_stern_generation(key, primenum)`

Return: a hard knapsack list

Example:

```

LIB "crypto.lib";
naccache_stern_generation(5,292);
⇒ 0
naccache_stern_generation(5,293);
⇒ [1]:
⇒      85
⇒ [2]:
⇒     164
⇒ [3]:
⇒     117
⇒ [4]:
⇒      44

```

D.12.2.48 naccache_stern_encryption

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `naccache_stern_encryption(knapsack, message, primenum)`

Return: an encrypted message as integer

Example:

```
LIB "crypto.lib";
//Please note that the values for primenum and hardknapsack have been obtained from t
list hardknapsack = 85,164,117,44;
int primenum = 293;
list message = 1,0,1,0;
naccache_stern_encryption(hardknapsack,message,primenum);
⇒ 9945
```

D.12.2.49 naccache_stern_decryption

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `naccache_stern_decryption(knapsack, key, primenum, message)`

Return: decrypted binary list

Example:

```
LIB "crypto.lib";
//Please note that the values have been obtained from the example of naccache_stern_g
int primenum = 293;
int message = 9945;
int key = 5;
list hardknapsack = 85,164,117,44;
naccache_stern_decryption(hardknapsack,key,primenum,message);
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 0
⇒ [3]:
⇒ 1
⇒ [4]:
⇒ 0
```

D.12.2.50 m_merkle_hellman_transformation

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `m_merkle_hellman_transformation(knapsack, primitive, mod1)`

Return: list containing a hard knapsack

Example:

```
LIB "crypto.lib";
//Please note that the values for primenum and hardknapsack have been obtained from t
list knapsack = 2,3,5,7;
int mod1 = 211;
int primitive = 2;
m_merkle_hellman_transformation(knapsack,primitive,mod1);
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 43
⇒ [3]:
⇒ 132
⇒ [4]:
⇒ 139
```

D.12.2.51 m_merkle_hellman_encryption

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `m_merkle_hellman_encryption(knapsack, message)`

Return: an encrypted message as integer

Note: This works in the same way as `merkle_hellman_encryption`. The additional function is created to keep consistency with the needed functions for every kryptosystem.

Example:

```
LIB "crypto.lib";
//Please note that the values for primenum and hardknapsack have been obtained from t
list knapsack = 1,43,132,139;
list message = 1,0,0,1;
m_merkle_hellman_encryption(knapsack,message);
↳ 140
```

D.12.2.52 m_merkle_hellman_decryption

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `m_merkle_hellman_decryption(knapsack, primitive, mod1, message)`

Return: decrypted binary list

Example:

```
LIB "crypto.lib";
//Please note that the values have been obtained from the example of m_merkle_hellma
list knapsack = 2,3,5,7;
int message = 140;
bigint primitive = 2;
bigint mod1 = 211;
m_merkle_hellman_decryption(knapsack,primitive,mod1,message);
↳ [1]:
↳ 1
↳ [2]:
↳ 0
↳ [3]:
↳ 0
↳ [4]:
↳ 1
```

D.12.2.53 merkle_hellman_encryption

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `merkle_hellman_encryption(knapsack, message)`

Return: encrypted integer

Example:

```
LIB "crypto.lib";
//Please note that the values have been obtained from the example of merkle_hellman.
list hardknapsack = 3,9,15,13;
list message = 0,1,0,1;
merkle_hellman_encryption(hardknapsack,message);
↳ 22
```

D.12.2.54 merkle_hellman_decryption

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `merkle_hellman_decryption(knapsack, key, mod1, message)`

Return: decrypted binary list

Example:

```
LIB "crypto.lib";
//Please note that the values have been obtained from the example of merkle_hellman.
list hardknapsack =3,9,15,13;
int key = 3;
int message = 22;
int mod1 = 23;
merkle_hellman_decryption(hardknapsack, key, mod1, message);
↳ 15
↳ [1]:
↳ 0
↳ [2]:
↳ 1
↳ [3]:
↳ 0
↳ [4]:
↳ 1
```

D.12.2.55 super_increasing_knapsack

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `super_increasing_knapsack(ksize)`

Return: super-increasing knapsack list

Example:

```
LIB "crypto.lib";
super_increasing_knapsack(10);
↳ [1]:
↳ 512
↳ [2]:
↳ 256
↳ [3]:
↳ 128
↳ [4]:
↳ 64
↳ [5]:
↳ 32
↳ [6]:
↳ 16
↳ [7]:
↳ 8
↳ [8]:
↳ 4
↳ [9]:
↳ 2
↳ [10]:
↳ 1
```

D.12.2.56 h_increasing_knapsack

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `h_increasing_knapsack(ksize, h)`

Return: h-increasing knapsack list

Example:

```
LIB "crypto.lib";
h_increasing_knapsack(10,5);
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 2
⇒ [3]:
⇒ 4
⇒ [4]:
⇒ 8
⇒ [5]:
⇒ 16
⇒ [6]:
⇒ 32
⇒ [7]:
⇒ 63
⇒ [8]:
⇒ 124
⇒ [9]:
⇒ 244
⇒ [10]:
⇒ 480
```

D.12.2.57 injective_knapsack

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `injective_knapsack(ksize, kmaxelement)`

Return: list of injective knapsacks with maximal element `kmaxelement` and size `ksize`

Example:

```
LIB "crypto.lib";
injective_knapsack(3,9);
⇒ [1]:
⇒ [1]:
⇒ 9
⇒ [2]:
⇒ 1
⇒ [3]:
⇒ 3
⇒ [2]:
⇒ [1]:
⇒ 9
⇒ [2]:
⇒ 1
⇒ [3]:
```

D.12.2.58 calculate_max_sum

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\]](#), page 1993).

Usage: `calculate_max_sum(a)`

Return: sum of all elements in a

Example:

```
LIB "crypto.lib";
list a = 1,5,3,2,12;
calculate_max_sum(a);
↦ 23
```

D.12.2.59 `set_is_injective`

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `set_is_injective(a)`

Return: 1 if a is injective, 0 otherwise

Example:

```
LIB "crypto.lib";
list inj = 1,5,7,41;
list non_inj = 1,2,3,4;
set_is_injective(inj);
↦ 1
set_is_injective(non_inj);
↦ 0
```

D.12.2.60 `is_h_injective`

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `is_h_injective(a, h)`

Return: 1 if a is h-injective, 0 otherwise

Example:

```
LIB "crypto.lib";
list h_inj = 1,2,4,10,17;
is_h_injective(h_inj,3);
↦ 1
//1+2+4+10=17
is_h_injective(h_inj,4);
↦ 0
```

D.12.2.61 `is_fix_injective`

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `is_fix_injective(a)`

Return: 1 if a is fix-injective, 0 otherwise

Example:

```
LIB "crypto.lib";
//this is fix-injective because 17=10+2+4+1 with different numbers of addends.
list fix_inj = 1,2,4,10,17;
//this is not fix-injective because 4+1=2+3.
```

```

list not_fix_inj = 1,2,3,4;
is_fix_injective(fix_inj);
↳ 1
is_fix_injective(not_fix_inj);
↳ 0

```

D.12.2.62 three_elements

Procedure from library `crypto.lib` (see [Section D.12.2 \[crypto.lib\], page 1993](#)).

Usage: `three_elements(out, iterations)`

Return: Injective_knapsack created with the three elements method

Example:

```

LIB "crypto.lib";
//this is fix-injective because 17=10+2+4+1 with different numbers of addends.
list super_increasing = 1,2,4,10,20;
list a = three_elements(super_increasing,2);
a;

set_is_injective(a);
↳ 1

```

D.12.3 hyperel_lib

Library: `hyperel.lib`

Author: Markus Hochstetter, markushochstetter@gmx.de

Note: The library provides procedures for computing with divisors in the jacobian of hyper-elliptic curves. In addition procedures are available for computing the rational representation of divisors and vice versa. The library is intended to be used for teaching and demonstrating purposes but not for efficient computations.

Procedures:

D.12.3.1 ishyper

Procedure from library `hyperel.lib` (see [Section D.12.3 \[hyperel.lib\]](#), page 2019).

Usage: `ishyper(h,f);` $h, f = \text{poly}$

Return: 1 if $y^2 + h(x)y = f(x)$ is hyperelliptic, 0 otherwise

Note: Tests, if $y^2 + h(x)y = f(x)$ is a hyperelliptic curve.
Curve is defined over basering. Additionally shows error-messages.

Example:

```
LIB "hyperel.lib";
ring R=7,x,dp;
// hyperelliptic curve  $y^2 + h*y = f$ 
poly h=x;
poly f=x5+5x4+6x2+x+3;
ishyper(h,f);
↦ 1
```

D.12.3.2 isoncurve

Procedure from library `hyperel.lib` (see [Section D.12.3 \[hyperel.lib\]](#), page 2019).

Usage: `isoncurve(P,h,f);` $h, f = \text{poly}$; $P = \text{list}$

Return: 1 or 0 (if P is on curve or not)

Note: Tests, if $P = (P[1], P[2])$ is on the hyperelliptic curve $y^2 + h(x)y = f(x)$. Curve is defined over basering.

Example:

```
LIB "hyperel.lib";
ring R=7,x,dp;
// hyperelliptic curve  $y^2 + h*y = f$ 
poly h=x;
poly f=x5+5x4+6x2+x+3;
list P=2,3;
isoncurve(P,h,f);
↦ 1
```

D.12.3.3 chinrestp

Procedure from library `hyperel.lib` (see [Section D.12.3 \[hyperel.lib\]](#), page 2019).

Usage: `chinrestp(b,moduli);` $b, \text{moduli} = \text{list of polynomials}$

Return: $\text{poly } x$, s.t. $x = b[i] \bmod \text{moduli}[i]$

Note: chinese remainder theorem for polynomials

Example:

```
LIB "hyperel.lib";
ring R=7,x,dp;
list b=3x-4, -3x2+1, 1, 4;
list moduli=(x-2)^2, (x-5)^3, x-1, x-6;
chinrestp(b,moduli);
↦ -x6-3x5-x4+2x3-2x2+3x+3
```

D.12.3.4 norm

Procedure from library `hyperel.lib` (see [Section D.12.3 \[hyperel.lib\], page 2019](#)).

Usage: `norm(a,b,h,f);`

Return: norm of $a(x)-b(x)y$ in $\text{IF}[C]$

Note: The norm is a polynomial in just one variable.
Curve $C: y^2+h(x)y=f(x)$ is defined over basering.

Example:

```
LIB "hyperel.lib";
ring R=7,x,dp;
// hyperelliptic curve y^2 + h*y = f
poly h=x;
poly f=x5+5x4+6x2+x+3;
poly a=x2+1;
poly b=x;
norm(a,b,h,f);
↦ -x7+2x6+3x4-x3+1
```

D.12.3.5 multi

Procedure from library `hyperel.lib` (see [Section D.12.3 \[hyperel.lib\], page 2019](#)).

Usage: `multi(a,b,c,d,h,f);`

Return: list L with $L[1]-L[2]y=(a(x)-b(x)y)*(c(x)-d(x)y)$ in $\text{IF}[C]$

Note: Curve $C: y^2+h(x)y=f(x)$ is defined over basering.

Example:

```
LIB "hyperel.lib";
ring R=7,x,dp;
poly h=x;
poly f=x5+5x4+6x2+x+3;
// hyperelliptic curve y^2 + h*y = f
poly a=x2+1;
poly b=x;
poly c=5;
poly d=-x;
multi(a,b,c,d,h,f);
↦ [1]:
↦ -x7+2x6+x4-x3+2x2-2
↦ [2]:
↦ -2x3-3x
```

D.12.3.6 divisor

Procedure from library `hyperel.lib` (see [Section D.12.3 \[hyperel.lib\], page 2019](#)).

Usage: `divisor(a,b,h,f);` optional: `divisor(a,b,h,f,s);` $s=0,1$

Return: list P

Note: $P[1][3]*(P[1][1], P[1][2]) + \dots + P[\text{size}(P)][3]*$
 $*(P[\text{size}(P)][1], P[\text{size}(P)][2]) - (*)_{\text{infty}} = \text{div}(a(x)-b(x)y)$ if there is an optional parameter $s!=0$, then divisor additionally returns a parameter, which says, whether irreducible polynomials occurred during computations or not. Otherwise only warnings are displayed on the monitor. For $s=0$ nothing happens.
 Curve $C: y^2+h(x)y=f(x)$ is defined over basering.

Example:

```
LIB "hyperel.lib";
ring R=7,x,dp;
// hyperelliptic curve y^2 + h*y = f
poly h=x;
poly f=x5+5x4+6x2+x+3;
poly a=(x-1)^2*(x-6);
poly b=0;
divisor(a,b,h,f,1);
↳ [1]:
↳   [1]:
↳     -1
↳   [2]:
↳     -3
↳   [3]:
↳     2
↳ [2]:
↳   [1]:
↳     1
↳   [2]:
↳     -2
↳   [3]:
↳     2
↳ [3]:
↳   [1]:
↳     1
↳   [2]:
↳     1
↳   [3]:
↳     2
↳ 0
```

D.12.3.7 gcddivisor

Procedure from library `hyperel.lib` (see [Section D.12.3 \[hyperel.lib\]](#), page 2019).

Usage: `gcddivisor(p,q);`

Return: list P

Note: gcd of two divisors

Example:

```
LIB "hyperel.lib";
ring R=7,x,dp;
// hyperelliptic curve y^2 + h*y = f
poly h=x;
poly f=x5+5x4+6x2+x+3;
```

```
// two divisors
list p=list(-1,-3,1),list(1,1,2);
list q=list(1,1,1),list(2,2,1);
gcddivisor(p,q);
↳ [1]:
↳   [1]:
↳     1
↳   [2]:
↳     1
↳   [3]:
↳     1
```

D.12.3.8 semidiv

Procedure from library `hyperel.lib` (see [Section D.12.3 \[hyperel.lib\]](#), page 2019).

Usage: `semidiv(D,h,f);`

Return: list P

Note: important: Divisor D has to be semireduced!
 Computes semireduced divisor $P[1][3]*(P[1][1], P[1][2]) + \dots + P[\text{size}(P)][3]*$
 $*(P[\text{size}(P)][1], P[\text{size}(P)][2]) - (*)_{\infty} = \text{div}(D[1], D[2])$
 Curve $C: y^2 + h(x)y = f(x)$ is defined over basering.

Example:

```
LIB "hyperel.lib";
ring R=7,x,dp;
// hyperelliptic curve y^2 + h*y = f
poly h=x;
poly f=x5+5x4+6x2+x+3;
// Divisor
list D=x2-1,2x-1;
semidiv(D,h,f);
↳ [1]:
↳   [1]:
↳     -1
↳   [2]:
↳     -3
↳   [3]:
↳     1
↳ [2]:
↳   [1]:
↳     1
↳   [2]:
↳     1
↳   [3]:
↳     1
```

D.12.3.9 cantoradd

Procedure from library `hyperel.lib` (see [Section D.12.3 \[hyperel.lib\]](#), page 2019).

Usage: `cantoradd(D,Q,h,f);`

Return: list P

Note: Cantor's Algorithm - composition
important: D and Q have to be semireduced!
Computes semireduced divisor $\text{div}(P[1], P[2]) = \text{div}(D[1], D[2]) + \text{div}(Q[1], Q[2])$ The divisors are defined over the basering.
Curve C: $y^2 + h(x)y = f(x)$ is defined over the basering.

Example:

```
LIB "hyperel.lib";
ring R=7,x,dp;
// hyperelliptic curve y^2 + h*y = f
poly h=x;
poly f=x5+5x4+6x2+x+3;
// two divisors in rational representation
list D=x2-1,2x-1;
list Q=x2-3x+2,-3x+1;
cantoradd(D,Q,h,f);
⇒ [1]:
⇒ x2-x-2
⇒ [2]:
⇒ -3x+1
```

D.12.3.10 cantorred

Procedure from library `hyperel.lib` (see [Section D.12.3 \[hyperel.lib\]](#), page 2019).

Usage: `cantorred(D,h,f);`

Return: list N

Note: Cantor's algorithm - reduction.
important: Divisor D has to be semireduced!
Computes reduced divisor $\text{div}(N[1], N[2]) = \text{div}(D[1], D[2])$.
The divisors are defined over the basering.
Curve C: $y^2 + h(x)y = f(x)$ is defined over the basering.

Example:

```
LIB "hyperel.lib";
ring R=7,x,dp;
// hyperelliptic curve y^2 + h*y = f
poly h=x;
poly f=x5+5x4+6x2+x+3;
// semireduced divisor
list D=2x4+3x3-3x-2, -x3-2x2+3x+1;
cantorred(D,h,f);
⇒ [1]:
⇒ x2-2x+2
⇒ [2]:
⇒ 2x-2
```

D.12.3.11 double

Procedure from library `hyperel.lib` (see [Section D.12.3 \[hyperel.lib\]](#), page 2019).

Usage: `double(D,h,f);`

Return: list $Q=2*D$

Note: important: Divisor D has to be semireduced!
 Special case of Cantor's algorithm.
 Computes reduced divisor $\text{div}(Q[1], Q[2]) = 2 * \text{div}(D[1], D[2])$.
 The divisors are defined over the basering.
 Curve $C: y^2 + h(x)y = f(x)$ is defined over the basering.

Example:

```
LIB "hyperel.lib";
ring R=7,x,dp;
// hyperelliptic curve y^2 + h*y = f
poly h=x;
poly f=x5+5x4+6x2+x+3;
// reduced divisor
list D=x2-1,2x-1;
double(D,h,f);
⇒ [1]:
⇒ x2-2x+1
⇒ [2]:
⇒ 3x-2
```

D.12.3.12 cantormult

Procedure from library `hyperel.lib` (see [Section D.12.3 \[hyperel.lib\]](#), page 2019).

Usage: `cantormult(m,D,h,f);`

Return: `list res=m*D`

Note: important: Divisor D has to be semireduced!
 Uses repeated doublings for a faster computation
 of the reduced divisor $m*D$.
 Attention: Factor $m=\text{int}$, this means bounded.
 For $m < 0$ the inverse of $m*D$ is returned.
 The divisors are defined over the basering.
 Curve $C: y^2 + h(x)y = f(x)$ is defined over the basering.

Example:

```
LIB "hyperel.lib";
ring R=7,x,dp;
// hyperelliptic curve y^2 + h*y = f
poly h=x;
poly f=x5+5x4+6x2+x+3;
// reduced divisor
list D=x2-1,2x-1;
cantormult(34,D,h,f);
⇒ [1]:
⇒ x2-3x-3
⇒ [2]:
⇒ x+1
```

D.12.4 teachstd_lib

Library: `teachstd.lib`

Purpose: Procedures for teaching standard bases

Author: G.-M. Greuel, greuel@mathematik.uni-kl.de

Note: The library is intended to be used for teaching purposes, but not for serious computations. Sufficiently high printlevel allows to control each step, thus illustrating the algorithms at work. The procedures are implemented exactly as described in the book 'A SINGULAR Introduction to Commutative Algebra' by G.-M. Greuel and G. Pfister (Springer 2002).

Procedures:

D.12.4.1 ecart

Procedure from library `teachstd.lib` (see [Section D.12.4 \[teachstd.lib\], page 2025](#)).

Usage: `ecart(f)`; `f` poly or vector

Return: the ecart `e` of `f` of type `int`

Example:

```
LIB "teachstd.lib";
ring r=0,(x,y,z),ls;
ecart((y+z+x+xyz)**2);
  ↪ 4
ring s=0,(x,y,z),dp;
ecart((y+z+x+xyz)**2);
  ↪ 0
```

D.12.4.2 tail

Procedure from library `teachstd.lib` (see [Section D.12.4 \[teachstd.lib\], page 2025](#)).

Usage: `tail(f)`; `f` poly or vector

Return: `f-lead(f)`, the tail of `f` of type `poly`

Example:

```
LIB "teachstd.lib";
ring r=0,(x,y,z),ls;
tail((y+z+x+xyz)**2);
  ↪ 2yz+y2+2xz+2xy+2xyz2+2xy2z+x2+2x2yz+x2y2z2
ring s=0,(x,y,z),dp;
tail((y+z+x+xyz)**2);
  ↪ 2x2yz+2xy2z+2xyz2+x2+2xy+y2+2xz+2yz+z2
```

D.12.4.3 sameComponent

Procedure from library `teachstd.lib` (see [Section D.12.4 \[teachstd.lib\], page 2025](#)).

Usage: `sameComponent(f,g)`; `f,g` poly or vector

Return: 1 if `f` and `g` are of type `poly` or if `f` and `g` are of type `vector` and their leading monomials involve the same module component, 0 if not

Example:

```
LIB "teachstd.lib";
ring r=0,(x,y,z),dp;
sameComponent([y+z+x,xyz],[z2,xyz]);
```

```

↳ 1
sameComponent([y+z+x,xyz],[z4,xyz]);
↳ 0
sameComponent(y+z+x+xyz, xy+z5);
↳ 1

```

D.12.4.4 leadmonomial

Procedure from library `teachstd.lib` (see [Section D.12.4 \[teachstd.lib\], page 2025](#)).

Usage: `leadmonomial(f)`; f poly or vector

Return: the leading monomial of f of type poly

Note: if f is of type poly, `leadmonomial(f)=leadmonom(f)`, if f is of type vector and if `leadmonom(f)=m*gen(i)` then `leadmonomial(f)=m`

Example:

```

LIB "teachstd.lib";
ring s=0,(x,y,z),(c,dp);
leadmonomial((y+z+x+xyz)^2);
↳ x2y2z2
leadmonomial([(y+z+x+xyz)^2,xyz5]);
↳ x2y2z2

```

D.12.4.5 monomialLcm

Procedure from library `teachstd.lib` (see [Section D.12.4 \[teachstd.lib\], page 2025](#)).

Usage: `monomialLcm(m,n)`; m,n of type poly or vector

Return: least common multiple of leading monomials of m and n , of type poly

Note: if $m = (x_1 \dots x_r)^{(a_1, \dots, a_r)} \cdot \text{gen}(i)$ ($\text{gen}(i)=1$ if m is of type poly) and $n = (x_1 \dots x_r)^{(b_1, \dots, b_r)} \cdot \text{gen}(j)$, then the proc returns $(x_1 \dots x_r)^{(\max(a_1, b_1), \dots, \max(a_r, b_r))}$ if $i=j$ and 0 if $i \neq j$.

Example:

```

LIB "teachstd.lib";
ring r=0,(x,y,z),ds;
monomialLcm(xy2,yz3);
↳ xy2z3
monomialLcm([xy2,xz],[yz3]);
↳ 0
monomialLcm([xy2,xz3],[yz3]);
↳ xy2z3

```

D.12.4.6 spoly

Procedure from library `teachstd.lib` (see [Section D.12.4 \[teachstd.lib\], page 2025](#)).

Usage: `spoly(f,g[s])`; f,g poly or vector, s int

Return: the s -polynomial of f and g , of type poly or vector
if $s \neq 0$ the symmetric s -polynomial (without division) is returned

Example:

```

LIB "teachstd.lib";
ring r=0,(x,y,z),ls;
spoly(2x2+x2y,3y3+xyz);
  ↦ x2y4-2/3x3yz
ring s=0,(x,y,z),(c,dp);
spoly(2x2+x2y,3y3+xyz);
  ↦ -1/3x3yz+2x2y2
spoly(2x2+x2y,3y3+xyz,1);           //symmetric s-poly without division
  ↦ -x3yz+6x2y2
spoly([5x2+x2y,z5],[x2,y3,y4]);     //s-poly for vectors
  ↦ [5x2,z5-y4,-y5]

```

D.12.4.7 minEcart

Procedure from library `teachstd.lib` (see [Section D.12.4 \[teachstd.lib\], page 2025](#)).

Usage: `minEcart(T,h)`; T ideal or module, h poly or vector

Return: element g from T such that `leadmonom(g)` divides `leadmonom(h)`
`ecart(g)` is minimal with this property (if $T \neq 0$);
 return 0 if T is 0 or $h = 0$

Example:

```

LIB "teachstd.lib";
ring R=0,(x,y,z),dp;
ideal T = x2y+x2,y3+xyz,xyz2+z4;
poly h = x2y2z2+x5+yx3+z6;
minEcart(T,h);"";
  ↦ x2y+x2
  ↦
ring S=0,(x,y,z),(c,ds);
module T = [x2+x2y,y2],[y3+xyz,x3-z3],[x3y+z4,0,x2];
vector h = [x3y+x5+x2y2z2+z6,x3];
minEcart(T,h);
  ↦ [x3y+z4,0,x2]

```

D.12.4.8 NFMora

Procedure from library `teachstd.lib` (see [Section D.12.4 \[teachstd.lib\], page 2025](#)).

Usage: `NFMora(f,G[s])`; f poly or vector, G ideal or module, s int

Return: the Mora normal form of f w.r.t. G, same type as f
 if $s \neq 0$ the symmetric s-polynomial (without division) is used

Note: Show comments if `printlevel > 0`, pauses computation if `printlevel > 1`

Example:

```

LIB "teachstd.lib";
ring r=0,(x,y,z),dp;
poly f = x2y2z2+x5+yx3+z6-3y3;
ideal G = x2y+x2,y3+xyz,xyz2+z6;
NFMora(f,G);"";
  ↦ x5-x2yz2+x3y-xyz2-3y3
  ↦
ring s=0,(x,y,z),ds;

```

```

poly f = x3y+x5+x2y2z2+z6;
ideal G = x2+x2y,y3+xyz,x3y2+z4;
NFMora(f,G);"";
↳ 0
↳
vector v = [f,x2+x2y];
module M = [x2+x2y,f],[y3+xyz,y3],[x3y2+z4,z2];
NFMora(v,M);
↳ x2*gen(2)+x2y*gen(2)+x3y*gen(1)+x5*gen(1)+x2y2z2*gen(1)+z6*gen(1)

```

D.12.4.9 prodcrit

Procedure from library `teachstd.lib` (see [Section D.12.4 \[teachstd.lib\], page 2025](#)).

Usage: `prodcrit(f,g[o]);` f, g poly or vector, and optional int argument o

Return: 1 if product criterion applies in the same module component, 2 if `lead(f)` and `lead(g)` involve different components, 0 else

Note: if product criterion applies we can delete (f, g) from pairset. This procedure returns 0 if o is given and is a positive integer, or you may set the attribute "default_arg" for `prodcrit` to 1.

Example:

```

LIB "teachstd.lib";
ring r=0,(x,y,z),dp;
poly f = y3z3+x5+yx3+z6;
poly g = x5+yx3;
prodcrit(f,g);
↳ 1
vector v = x3z2*gen(1)+x3y*gen(1)+x2y*gen(2);
vector w = y4*gen(1)+y3*gen(2)+xyz*gen(1);
prodcrit(v,w);
↳ 0

```

D.12.4.10 chaincrit

Procedure from library `teachstd.lib` (see [Section D.12.4 \[teachstd.lib\], page 2025](#)).

Usage: `chaincrit(f,g,h);` f, g, h poly or module

Return: 1 if chain criterion applies, 0 else

Note: if chain criterion applies to f, g, h we can delete (g, h) from pairset

Example:

```

LIB "teachstd.lib";
ring r=0,(x,y,z),dp;
poly f = x2y2z2+x5+yx3+z6;
poly g = x5+yx3;
poly h = y2z5+x5+yx3;
chaincrit(f,g,h);
↳ 1
vector u = [x2y3-z2,x2y];
vector v = [x2y2+z2,x2-y2];
vector w = [x2y4+z3,x2+y2];
chaincrit(u,v,w);
↳ 1

```

D.12.4.11 pairset

Procedure from library `teachstd.lib` (see [Section D.12.4 \[teachstd.lib\], page 2025](#)).

Usage: `pairset(G)`; G ideal or module

Return: list L ,
 $L[1]$ = the pairset of G as list (not containing pairs for which the product or the chain criterion applies),
 $L[2]$ = intvec v , $v[1]$ = # product criterion, $v[2]$ = # chain criterion

Example:

```
LIB "teachstd.lib";
ring r=0,(x,y,z),dp;
ideal G = x2y+x2,y3+xyz,xyz2+z4;
pairset(G);"";
⇒ [1]:
⇒ [1]:
⇒ [1]=x2y+x2
⇒ [2]=y3+xyz
⇒ [2]:
⇒ [1]=x2y+x2
⇒ [2]=xyz2+z4
⇒ [3]:
⇒ [1]=y3+xyz
⇒ [2]=xyz2+z4
⇒ [2]:
⇒ 0,0
⇒
module T = [x2y3-z2,x2y],[x2y2+z2,x2-y2],[x2y4+z3,x2+y2];
pairset(T);
⇒ [1]:
⇒ [1]:
⇒ [1]=x2y3*gen(1)+x2y*gen(2)-z2*gen(1)
⇒ [2]=x2y2*gen(1)+x2*gen(2)-y2*gen(2)+z2*gen(1)
⇒ [2]:
⇒ [1]=x2y3*gen(1)+x2y*gen(2)-z2*gen(1)
⇒ [2]=x2y4*gen(1)+z3*gen(1)+x2*gen(2)+y2*gen(2)
⇒ [2]:
⇒ 0,1
```

D.12.4.12 updatePairs

Procedure from library `teachstd.lib` (see [Section D.12.4 \[teachstd.lib\], page 2025](#)).

Usage: `updatePairs(P,S,h)`; P list, S ideal or module, h poly or vector
 P a list of pairs of polys or vectors (obtained from `pairset`)

Return: list Q ,
 $Q[1]$ = the pairset P enlarged by all pairs (f,h) , f from S , without pairs for which the product or the chain criterion applies
 $Q[2]$ = intvec v , $v[1]$ = # product criterion, $v[2]$ = # chain criterion

Example:

```

LIB "teachstd.lib";
ring R1=0,(x,y,z),(c,dp);
ideal S = x2y+x2,y3+xyz;
poly h = x2y+xyz;
list P = pairset(S)[1];
P;"";
⇒ [1]:
⇒   _[1]=x2y+x2
⇒   _[2]=y3+xyz
⇒
updatePairs(P,S,h);"";
⇒ [1]:
⇒   [1]:
⇒     _[1]=x2y+x2
⇒     _[2]=y3+xyz
⇒   [2]:
⇒     _[1]=x2y+x2
⇒     _[2]=x2y+xyz
⇒ [2]:
⇒   0,1
⇒
module T = [x2y3-z2,x2y],[x2y4+z3,x2+y2];
P = pairset(T)[1];
P;"";
⇒ [1]:
⇒   _[1]=[x2y3-z2,x2y]
⇒   _[2]=[x2y4+z3,x2+y2]
⇒
updatePairs(P,T,[x2+x2y,y3+xyz]);
⇒ [1]:
⇒   [1]:
⇒     _[1]=[x2y3-z2,x2y]
⇒     _[2]=[x2y4+z3,x2+y2]
⇒   [2]:
⇒     _[1]=[x2y3-z2,x2y]
⇒     _[2]=[x2y+x2,y3+xyz]
⇒ [2]:
⇒   0,1

```

D.12.4.13 standard

Procedure from library `teachstd.lib` (see [Section D.12.4 \[teachstd.lib\]](#), page 2025).

Usage: `standard(i[s]);` id ideal or module, s int

Return: a standard basis of id, using generalized Mora's algorithm which is Buchberger's algorithm for global monomial orderings. If $s!=0$ the symmetric s-polynomial (without division) is used

Note: Show comments if `printlevel > 0`, pauses computation if `printlevel > 1`

Example:

```

LIB "teachstd.lib";
ring r=0,(x,y,z),dp;
ideal G = x2y+x2,y3+xyz,xyz2+z4;

```

```

standard(G);"";
↳ _[1]=x2y+x2
↳ _[2]=y3+xyz
↳ _[3]=xyz2+z4
↳ _[4]=x3z-x2y
↳ _[5]=-xz4+x2z2
↳ _[6]=-y2z4-x2z3
↳ _[7]=z6+x2yz2
↳ _[8]=x2z3-x3z
↳ _[9]=-x2z2+x3
↳ _[10]=x4-x2yz
↳
ring s=0,(x,y,z),(c,ds);
ideal G = 2x2+x2y,y3+xyz,3x3y+z4;
standard(G);"";
↳ _[1]=2x2+x2y
↳ _[2]=y3+xyz
↳ _[3]=3x3y+z4
↳ _[4]=-2/3z4+x3y2
↳
standard(G,1);"";           //use symmetric s-poly without division
↳ _[1]=2x2+x2y
↳ _[2]=y3+xyz
↳ _[3]=3x3y+z4
↳ _[4]=-2z4+3x3y2
↳
module M = [2x2,x3y+z4],[3y3+xyz,y3],[5z4,z2];
standard(M);
↳ _[1]=[2x2,x3y+z4]
↳ _[2]=[3y3+xyz,y3]
↳ _[3]=[5z4,z2]
↳ _[4]=[0,-2/3x2y3+x3y4+1/3x4y2z+y3z4+1/3xyz5]
↳ _[5]=[0,-2/5x2z2+x3yz4+z8]
↳ _[6]=[0,-3/5y3z2-1/5xyz3+y3z4]

```

D.12.4.14 localstd

Procedure from library `teachstd.lib` (see [Section D.12.4 \[teachstd.lib\]](#), page 2025).

Usage: `localstd(id); id = ideal`

Return: A standard basis for a local degree ordering, using Lazard's method.

Note: The procedure homogenizes `id` w.r.t. a new 1st variable `local@t`, computes a SB w.r.t. $(dp(1), dp)$ and substitutes `local@t` by 1. Hence the result is a SB with respect to an ordering which sorts first w.r.t. the subdegree of the original variables and then refines it with `dp`. This is the local degree ordering `ds`.
`localstd` may be used in order to avoid cancellation of units and thus to be able to use `option(contentSB)` also for local orderings.

Example:

```

LIB "teachstd.lib";
ring R = 0,(x,y,z),ds;

D.12.5 weierstr_lib

Library: weierstr.lib

Purpose: Procedures for the Weierstrass Theorems

Author: G.-M. Greuel, greuel@mathematik.uni-kl.de

Procedures:

D.12.5.1 weierstrDiv

Procedure from library `weierstr.lib` (see [Section D.12.5 \[weierstr_lib\]](#), page 2033).

Usage: weierstrDiv(g,f,d); g,f=poly, d=integer

Assume: f must be general of finite order, say b, in the last ring variable, say T; if not use the procedure `lastvarGeneral` first

Purpose: perform the Weierstrass division of g by f up to order d

Return:

- a list, say l, of two polynomials and an integer, such that $g = l[1]*f + l[2]$, $\deg_T(l[2]) < b$, up to (including) total degree d
- l[3] is the number of iterations used
- if f is not T-general, return (0,g)

Note: the procedure works for any monomial ordering

Theory: the proof of Grauert-Remmert (Analytische Stellenalgebren) is used for the algorithm

Example:

```

LIB "weierstr.lib";
ring R = 0,(x,y),ds;
poly f = y - xy2 + x2;
poly g = y;
list l = weierstrDiv(g,f,10); l;"";
⇒ [1]:
⇒ 1+xy-x3+x2y2-2x4y+2x6+x3y3-3x5y2+5x7y+x4y4-5x9-4x6y3+9x8y2+x5y5

```

```

⇒ [2] :
⇒      -x2+x5-2x8
⇒ [3] :
⇒      5
⇒
l[1]*f + l[2];           //g = l[1]*f+l[2] up to degree 10
⇒ y-5x11+14x10y2+5x7y5-9x9y4-x6y7

```

D.12.5.2 weierstrPrep

Procedure from library `weierstr.lib` (see [Section D.12.5 \[weierstr.lib\]](#), page 2033).

Usage: `weierstrPrep(f,d); f=poly, d=integer`

Assume: `f` must be general of finite order, say `b`, in the last ring variable, say `T`; if not apply the procedure `lastvarGeneral` first

Purpose: perform the Weierstrass preparation of `f` up to order `d`

Return: - a list, say `l`, of two polynomials and one integer,
`l[1]` a unit, `l[2]` a Weierstrass polynomial, `l[3]` an integer such that $l[1]*f = l[2]$, where `l[2]` is a Weierstrass polynomial, (i.e. $l[2] = T^b + \text{lower terms in } T$) up to (including) total degree `d` `l[3]` is the number of iterations used
 - if `f` is not `T`-general, return (0,0)

Note: the procedure works for any monomial ordering

Theory: the proof of Grauert-Remmert (Analytische Stellenalgebren) is used for the algorithm

Example:

```

LIB "weierstr.lib";
ring R = 0,(x,y),ds;
poly f = xy+y2+y4;
list l = weierstrPrep(f,5); l; ""
⇒ [1] :
⇒      1-x2+xy-y2+3x4-3x3y+3x2y2-2xy3+y4
⇒ [2] :
⇒      xy+y2-x3y
⇒ [3] :
⇒      6
⇒
f*l[1]-l[2];           // = 0 up to degree 5
⇒ 3x5y+3x4y4-3x3y5+3x2y6-2xy7+y8

```

D.12.5.3 lastvarGeneral

Procedure from library `weierstr.lib` (see [Section D.12.5 \[weierstr.lib\]](#), page 2033).

Usage: `lastvarGeneral(f,d); f=poly`

Return: `poly`, say `g`, obtained from `f` by a generic change of variables, s.t. `g` is general of finite order `b` w.r.t. the last ring variable, say `T` (i.e. $g(0,\dots,0,T) = c*T^b + \text{higher terms}$, $c \neq 0$)

Note: the procedure works for any monomial ordering

Example:

```
LIB "weierstr.lib";
ring R = 2,(x,y,z),ls;
poly f = xyz;
lastvarGeneral(f);
↦ z24+yz19+xz6+xyz
```

D.12.5.4 generalOrder

Procedure from library `weierstr.lib` (see [Section D.12.5 \[weierstr.lib\]](#), page 2033).

Usage: `generalOrder(f); f=poly`

Return: integer b if f is general of order b w.r.t. the last variable, say T , resp. -1 if not (i.e. $f(0,\dots,0,T)$ is of order b , resp. $f(0,\dots,0,T)=0$)

Note: the procedure works for any monomial ordering

Example:

```
LIB "weierstr.lib";
ring R = 0,(x,y),ds;
poly f = x2-4xy+4y2-2xy2+4y3+y4;
generalOrder(f);
↦ 2
```

D.12.6 rootsmr.lib

Library: `rootsmr.lib`

Purpose: Counting the number of real roots of polynomial systems

Author: Enrique A. Tobis, etobis@dc.uba.ar

Overview: Routines for counting the number of real roots of a multivariate polynomial system. Two methods are implemented: deterministic computation of the number of roots, via the signature of a certain bilinear form (`nrRootsDeterm`); and a rational univariate projection, using a pseudorandom polynomial (`nrRootsProbab`). It also includes a command to verify the correctness of the pseudorandom answer.

References:

Basu, Pollack, Roy, "Algorithms in Real Algebraic Geometry", Springer, 2003.

Procedures:

D.12.6.1 nrRootsProbab

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\]](#), page 2035).

Return: `int`: the number of real roots of the ideal I by a probabilistic algorithm

Assume: If I is not a Groebner basis, then a Groebner basis will be computed by using `std`. If I is already a Groebner basis (i.e. if `attrib(I,"isSB")`; returns 1) then this Groebner basis will be used, hence it must be one w.r.t. (any) global ordering. This may be useful if the ideal is known to be a Groebner basis or if it can be computed faster by a different method.

Note: If `n<10` is given, n is the number of digits being used for constructing a random characteristic polynomial, a bigger n is more safe but slower (default: $n=5$). If `printlevel>0` the number of complex solutions is displayed (default: `printlevel=0`).

Example:

```

LIB "rootsmr.lib";
ring r = 0,(x,y,z),lp;
ideal i = (x-1)*(x-2),(y-1)^3*(x-y),(z-1)*(z-2)*(z-3)^2;
nrRootsProbab(i);          //no of real roots (using internally std)
↪ 9
i = groebner(i);           //using the hilbert driven GB computation
int pr = printlevel;
printlevel = 2;
nrRootsProbab(i);
↪ //ideal has 32 complex solutions, counted with multiplicity
↪ *****
↪ * WARNING: This polynomial was obtained using pseudorandom numbers.*
↪ * If you want to verify the result, please use the command          *
↪ *                                                                    *
↪ * verify(p,b,i)                                                    *
↪ *                                                                    *
↪ * where p is the polynomial I returned, b is the monomial basis    *
↪ * used, and i the Groebner basis of the ideal                      *
↪ *****
↪ 9
printlevel = pr;

```

See also: [Section D.12.6.2 \[nrRootsDeterm\]](#), page 2036; [Section D.12.7.15 \[nrroots\]](#), page 2050; [Section D.12.6.9 \[randcharpoly\]](#), page 2040; [Section D.8.4.2 \[solve\]](#), page 1849.

D.12.6.2 nrRootsDeterm

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\]](#), page 2035).

Return: int: the number of real roots of the ideal I by a deterministic algorithm

Assume: If I is not a Groebner basis, then a Groebner basis will be computed by using std. If I is already a Groebner basis (i.e. if `attrib(I,"isSB")` returns 1) then this Groebner basis will be used, hence it must be one w.r.t. (any) global ordering. This may be useful if the ideal is known to be a Groebner basis or if it can be computed faster by a different method.

Note: If `printlevel>0` the number of complex solutions is displayed (default: `printlevel=0`). The procedure `nrRootsProbab` is usually faster.

Example:

```

LIB "rootsmr.lib";
ring r = 0,(x,y,z),lp;
ideal I = (x-1)*(x-2),(y-1),(z-1)*(z-2)*(z-3)^2;
nrRootsDeterm(I);          //no of real roots (using internally std)
↪ 6
I = groebner(I);           //using the hilbert driven GB computation
int pr = printlevel;
printlevel = 2;
nrRootsDeterm(I);
↪ //ideal has 8 complex solutions, counted with multiplicity
↪ 6
printlevel = pr;

```

See also: [Section D.12.6.1 \[nrRootsProbab\]](#), page 2035; [Section D.12.7.15 \[nrroots\]](#), page 2050; [Section D.8.4.2 \[solve\]](#), page 1849; [Section D.12.6.4 \[sturmquery\]](#), page 2037.

D.12.6.3 symsignature

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\]](#), page 2035).

Usage: `symsignature(m)`; `m` matrix. `m` must be symmetric.

Return: `int`: the signature of `m`

Example:

```
LIB "rootsmr.lib";
ring r = 0,(x,y),dp;
ideal i = x4-y2x,y2-13;
i = std(i);
ideal b = qbase(i);
matrix m = matbil(1,b,i);
symsignature(m);
↦ 4
```

See also: [Section D.12.6.5 \[matbil\]](#), page 2037; [Section D.12.6.4 \[sturmquery\]](#), page 2037.

D.12.6.4 sturmquery

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\]](#), page 2035).

Usage: `sturmquery(h,b,i)`; `h` poly, `b,i` ideal

Return: `int`: the Sturm query of `h` in $V(i)$

Assume: `i` is a Groebner basis, `b` is an ordered monomial basis of r/i , `r` = basering.

Example:

```
LIB "rootsmr.lib";
ring r = 0,(x,y),dp;
ideal i = x4-y2x,y2-13;
i = std(i);
ideal b = qbase(i);
sturmquery(1,b,i);
↦ 4
```

See also: [Section D.12.6.5 \[matbil\]](#), page 2037; [Section D.12.6.3 \[symsignature\]](#), page 2037.

D.12.6.5 matbil

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\]](#), page 2035).

Usage: `matbil(h,b,i)`; `h` poly, `b,i` ideal

Return: `matrix`: the matrix of the bilinear form $(f,g) \mapsto \text{trace}(m_fhg)$, `m_fhg` = multiplication with `fhg` on r/i

Assume: `i` is a Groebner basis and `b` is an ordered monomial basis of r/i , `r` = basering

Example:

```
LIB "rootsmr.lib";
ring r = 0,(x,y),dp;
ideal i = x4-y2x,y2-13;
i = std(i);
ideal b = qbase(i);
poly f = x3-xy+y-13+x4-y2x;
```

```

matrix m = matbil(f,b,i);
print(m);
⇒ 0,      13182, 0,      -13182,0,      0,      0,      1014,
⇒ 13182, 0,      -13182,0,      0,      0,      1014, 0,
⇒ 0,      -13182,0,      0,      0,      1014, 0,      -1014,
⇒ -13182,0,      0,      0,      1014, 0,      -1014,0,
⇒ 0,      0,      0,      1014, 0,      -1014,0,      0,
⇒ 0,      0,      1014, 0,      -1014,0,      0,      0,
⇒ 0,      1014, 0,      -1014, 0,      0,      -338, 104,
⇒ 1014, 0,      -1014, 0,      0,      0,      104, -26

```

See also: [Section D.12.6.6 \[matmult\], page 2038](#); [Section D.12.6.7 \[tracemult\], page 2038](#).

D.12.6.6 matmult

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\], page 2035](#)).

Usage: `matmult(f,b,i)`; f poly, b,i ideal

Return: matrix: the matrix of the multiplication map by f (m_f) on r/i w.r.t. to the monomial basis b of r/i ($r = \text{basering}$)

Assume: i is a Groebner basis and b is an ordered monomial basis of r/i , as given by `qbase(i)`

Example:

```

LIB "rootsmr.lib";
ring r = 0,(x,y),dp;
ideal i = x4-y2x,y2-13;
i = std(i);
ideal b = qbase(i);
poly f = x3-xy+y-13+x4-y2x;
matrix m = matmult(f,b,i);
print(m);
⇒ 0,      1,      0,      -1,0,      0,      1,      0,
⇒ 13,      0,      -13,0,      0,      0,      0,      1,
⇒ 0,      0,      0,      1, 0,      -1,0,      0,
⇒ 0,      0,      13, 0,      -13,0,      0,      0,
⇒ 0,      -13,0,      0, 0,      1, 0,      -1,
⇒ -169,0,      0,      0, 13, 0,      -13,0,
⇒ 0,      0,      0,      0, 0,      0,      -13,1,
⇒ 0,      0,      0,      0, 0,      0,      13, -13

```

See also: [Section D.12.6.8 \[coords\], page 2039](#); [Section D.12.6.5 \[matbil\], page 2037](#).

D.12.6.7 tracemult

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\], page 2035](#)).

Usage: `tracemult(f,B,I)`; f poly, B,I ideal

Return: number: the trace of the multiplication by f (m_f) on r/I , written in the monomial basis B of r/I , $r = \text{basering}$ (faster than `matmult + trace`)

Assume: I is given by a Groebner basis and B is an ordered monomial basis of r/I

Example:

```

LIB "rootsmr.lib";
ring r = 0,(x,y),dp;
ideal i = x4-y2x,y2-13;
i = std(i);
ideal b = qbase(i);
poly f = x3-xy+y-13+x4-y2x;
matrix m = matmult(f,b,i);
print(m);
⇒ 0, 1, 0, -1,0, 0, 1, 0,
⇒ 13, 0, -13,0, 0, 0, 0, 1,
⇒ 0, 0, 0, 1, 0, -1,0, 0,
⇒ 0, 0, 13, 0, -13,0, 0, 0,
⇒ 0, -13,0, 0, 0, 1, 0, -1,
⇒ -169,0, 0, 0, 13, 0, -13,0,
⇒ 0, 0, 0, 0, 0, 0, -13,1,
⇒ 0, 0, 0, 0, 0, 0, 13, -13
tracemult(f,b,i); //the trace of m
⇒ -26

```

See also: [Section D.12.6.6 \[matmult\]](#), page 2038; [Section 5.1.158 \[trace\]](#), page 281.

D.12.6.8 coords

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\]](#), page 2035).

Usage: `coords(f,b,i)`, f poly, b,i ideal

Return: list of numbers: the coordinates of the class of $f \pmod i$ in the monomial basis b

Assume: i is a Groebner basis and b is an ordered monomial basis of r/i , $r = \text{basering}$

Example:

```

LIB "rootsmr.lib";
ring r = 0,(x,y),dp;
ideal i = x4-y2x,y2-13;
poly f = x3-xy+y-13+x4-y2x;
i = std(i);
ideal b = qbase(i);
b;
⇒ b[1]=x3y
⇒ b[2]=x3
⇒ b[3]=x2y
⇒ b[4]=x2
⇒ b[5]=xy
⇒ b[6]=x
⇒ b[7]=y
⇒ b[8]=1
coords(f,b,i);

↳ [7]:
↳ 1
↳ [8]:
↳ -13

```

See also: [Section D.12.6.5 \[matbil\]](#), page 2037; [Section D.12.6.6 \[matmult\]](#), page 2038.

D.12.6.9 randcharpoly

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\]](#), page 2035).

Usage: `randcharpoly(b,i); randcharpoly(b,i,n);` `b,i` ideal; `n` int

Return: `poly`: the characteristic polynomial of a pseudorandom rational univariate projection having one zero per zero of `i`. If `n<10` is given, it is the number of digits being used for the pseudorandom coefficients (default: `n=5`)

Assume: `i` is a Groebner basis and `b` is an ordered monomial basis of `r/i`, `r = basering`

Note: shows a warning if `printlevel>0` (default: `printlevel=0`)

Example:

```

LIB "rootsmr.lib";
ring r = 0,(x,y,z),dp;
ideal i = (x-1)*(x-2),(y-1),(z-1)*(z-2)*(z-3)^2;
i = std(i);
ideal b = qbase(i);
poly p = randcharpoly(b,i);

D.12.6.10 verify

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\]](#), page 2035).

Usage: `verify(p,B,I);` p poly, B,I,ideal

Return: integer: 1 if and only if the polynomial p splits the points of $V(I)$. It's used to check the result of `randcharpoly`

Assume: I is given by a Groebner basis and B is an ordered monomial basis of r/I , $r = \text{basering}$

Note: comments the result if `printlevel>0` (default: `printlevel=0`)

Example:

```

LIB "rootsmr.lib";
ring r = 0,(x,y),dp;
poly f = x3-xy+y-13+x4-y2x;
ideal i = x4-y2x,y2-13;
i = std(i);
ideal b = qbase(i);
poly p = randcharpoly(b,i);
verify(p,b,i);
↪ 1

```

See also: [Section D.12.6.9 \[randcharpoly\]](#), page 2040.

D.12.6.11 randlinpoly

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\]](#), page 2035).

Usage: `randlinpoly();` `randlinpoly(n);` n int

Return: poly: linear combination of the variables of the ring, with pseudorandom coefficients. If $n < 10$ is given, it is the number of digits being used for the range of the coefficients (default: $n=5$)

Example:

```

LIB "rootsmr.lib";
ring r = 0,(x,y,z,w),dp;
poly p = randlinpoly();
p;
↪ 80035x+36642y+40875z+54263w
randlinpoly(5);
↪ 68857x+95664y+28174z+34170w

```

See also: [Section D.12.6.9 \[randcharpoly\]](#), page 2040.

D.12.6.12 powersums

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\]](#), page 2035).

Usage: `powersums(f,b,i);` f poly; b,i ideal

Return: list: the powersums of the results of evaluating f at the zeros of I

Assume: i is a Groebner basis and b is an ordered monomial basis of r/i , $r = \text{basering}$

Example:

```
LIB "rootsmr.lib";
ring r = 0,(x,y,z),dp;
ideal i = (x-1)*(x-2),(y-1),(z+5); // V(I) = {(1,1,-5),(2,1,-5)}
i = std(i);
ideal b = qbase(i);
poly f = x+y+z;
list psums = list(-2-3,4+9); // f evaluated at V(I) gives {-3,-2}
list l = powersums(f,b,i);
psums;
⇒ [1]:
⇒ -5
⇒ [2]:
⇒ 13
l;
⇒ [1]:
⇒ -5
⇒ [2]:
⇒ 13
```

See also: [Section D.12.6.13 \[symmfunc\]](#), page 2042.

D.12.6.13 symmfunc

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\]](#), page 2035).

Usage: `symmfunc(s); s list`

Return: list: the symmetric functions of the roots of a polynomial, given the power sums of those roots.

Example:

```
LIB "rootsmr.lib";
ring r = 0,x,dp;
poly p = (x-1)*(x-2)*(x-3);
list psums = list(1+2+3,1+4+9,1+8+27);
list l = symmfunc(psums);
l;
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ -6
⇒ [3]:
⇒ 11
⇒ [4]:
⇒ -6
p; // Compare p with the elements of l
⇒ x3-6x2+11x-6
```

See also: [Section D.12.6.12 \[powersums\]](#), page 2041.

D.12.6.14 univarpoly

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\]](#), page 2035).

Usage: `univarpoly(l); l list`

Return: `poly:` a polynomial `p` on the first variable of basering, say `x`, with $p = l[1] + l[2]*x + l[3]*x^2 + \dots$

Example:

```
LIB "rootsmr.lib";
ring r = 0,x,dp;
list l = list(1,2,3,4,5);
poly p = univarpoly(l);
p;
↪ x4+2x3+3x2+4x+5
```

D.12.6.15 qbase

Procedure from library `rootsmr.lib` (see [Section D.12.6 \[rootsmr.lib\]](#), page 2035).

Usage: `qbase(I); I zero-dimensional ideal`

Return: `ideal:` A monomial basis of the quotient between the basering and the ideal `I`, sorted according to the basering order.

Example:

```
LIB "rootsmr.lib";
ring r = 0,(x,y,z),dp;
ideal i = 2x2,-y2,z3;
i = std(i);
ideal b = qbase(i);
b;
↪ b[1]=xyz2
↪ b[2]=xyz
↪ b[3]=xz2
↪ b[4]=yz2
↪ b[5]=xy
↪ b[6]=xz
↪ b[7]=yz
↪ b[8]=z2
↪ b[9]=x
↪ b[10]=y
↪ b[11]=z
↪ b[12]=1
b = kbase(i);
b; // Compare this with the result of qbase
↪ b[1]=xyz2
↪ b[2]=yz2
↪ b[3]=xz2
↪ b[4]=z2
↪ b[5]=xyz
↪ b[6]=yz
↪ b[7]=xz
↪ b[8]=z
↪ b[9]=xy
↪ b[10]=y
↪ b[11]=x
↪ b[12]=1
```

See also: [Section 5.1.69 \[kbase\]](#), page 205.

D.12.7 rootsur_lib

Library: rootsur.lib

Purpose: Counting number of real roots of univariate polynomial

Author: Enrique A. Tobis, etobis@dc.uba.ar

Overview: Routines for bounding and counting the number of real roots of a univariate polynomial, by means of several different methods, namely Descartes' rule of signs, the Budan-Fourier theorem, Sturm sequences and Sturm-Habicht sequences. The first two give bounds on the number of roots. The other two compute the actual number of roots of the polynomial. There are several wrapper functions, to simplify the application of the aforesaid theorems and some functions to determine whether a given polynomial is univariate.

References:

Basu, Pollack, Roy, "Algorithms in Real Algebraic Geometry", Springer, 2003.

Procedures:

D.12.7.1 isuni

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur_lib\]](#), page 2044).

Usage: `isuni(p); poly p;`

Return: `poly`: if `p` is a univariate polynomial, it returns the variable. If not, zero.

Example:

```
LIB "rootsur.lib";
ring r = 0,(x,y),dp;
poly p = 6x7-3x2+2x-15/7;
isuni(p);
↪ x
isuni(p*y);
↪ 0
```

See also: [Section D.12.7.2 \[whichvariable\]](#), page 2044.

D.12.7.2 whichvariable

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur_lib\]](#), page 2044).

Usage: `whichvariable(p); poly p`

Return: `poly`: if `p` is a univariate monomial, the variable. Otherwise 0.

Assume: `p` is a monomial

Example:

```
LIB "rootsur.lib";
ring r = 0,(x,y),dp;
whichvariable(x5);
↪ x
whichvariable(x3y);
↪ 0
```

See also: [Section D.12.7.1 \[isuni\]](#), page 2044.

D.12.7.3 varsigns

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur.lib\]](#), page 2044).

Usage: `varsigns(l)`; list `l`.

Return: `int`: the number of sign changes in the list `l`

Example:

```
LIB "rootsur.lib";
ring r = 0,x,dp;
list l = 1,2,3;
varsigns(l);
↪ 0
l = 1,-1,2,-2,3,-3;
varsigns(l);
↪ 5
```

See also: [Section D.12.7.5 \[boundposDes\]](#), page 2045.

D.12.7.4 boundBuFou

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur.lib\]](#), page 2044).

Usage: `boundBuFou(p,a,b)`; `p` poly, `a,b` number

Return: `int`: an upper bound for the number of real roots of `p` in $(a,b]$, with the same parity as the actual number of roots (using the Budan-Fourier Theorem)

Assume: - `p` is a univariate polynomial with rational coefficients
 - `a`, `b` are rational numbers with $a < b$

Example:

```
LIB "rootsur.lib";
ring r = 0,x,dp;
poly p = (x+2)*(x-1)*(x-5);
boundBuFou(p,-3,5);
↪ 3
boundBuFou(p,-2,5);
↪ 2
```

See also: [Section D.12.7.5 \[boundposDes\]](#), page 2045; [Section D.12.7.3 \[varsigns\]](#), page 2045.

D.12.7.5 boundposDes

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur.lib\]](#), page 2044).

Usage: `boundposDes(p)`; poly `p`

Return: `int`: an upper bound for the number of positive roots of `p`, with the same parity as the actual number of positive roots of `p`.

Assume: `p` is a univariate polynomial with rational coefficients

Example:

```
LIB "rootsur.lib";
ring r = 0,x,dp;
poly p = (x+2)*(x-1)*(x-5);
boundposDes(p);
```

```

    ↪ 2
    p = p*(x2+1);
    boundposDes(p);
    ↪ 4

```

See also: [Section D.12.7.4 \[boundBuFou\]](#), page 2045.

D.12.7.6 boundDes

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur.lib\]](#), page 2044).

Usage: `boundDes(p); poly p`

Return: `int`: an upper bound for the number of real roots of `p`, with the same parity as the actual number of real roots of `p`.

Assume: `p` is a univariate polynomial with rational coefficients

Example:

```

LIB "rootsur.lib";
ring r = 0,x,dp;
poly p = (x+2)*(x-1)*(x-5);
boundDes(p);
↪ 3
p = p*(x2+1);
boundDes(p);
↪ 5

```

See also: [Section D.12.7.4 \[boundBuFou\]](#), page 2045.

D.12.7.7 allrealst

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur.lib\]](#), page 2044).

Usage: `allrealst(p); poly p`

Return: `int`: 1 if and only if all the roots of `p` are real, 0 otherwise. Checks by using Sturm's Theorem whether all the roots of `p` are real

Assume: `p` is a univariate polynomial with rational coefficients

Example:

```

LIB "rootsur.lib";
ring r = 0,x,dp;
poly p = (x+2)*(x-1)*(x-5);
allrealst(p);
↪ 1
p = p*(x2+1);
allrealst(p);
↪ 0

```

See also: [Section D.12.7.9 \[allreal\]](#), page 2047; [Section D.12.7.10 \[sturm\]](#), page 2047; [Section D.12.7.12 \[sturmha\]](#), page 2048.

D.12.7.8 maxabs

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur.lib\]](#), page 2044).

Usage: `maxabs(p);` poly `p`

Return: number: an upper bound for the largest absolute value of a root of `p`

Assume: `p` is a univariate polynomial with rational coefficients

Example:

```
LIB "rootsur.lib";
ring r = 0,x,dp;
poly p = (x+2)*(x-1)*(x-5);
maxabs(p);
↦ 11
```

See also: [Section D.12.7.10 \[sturm\]](#), page 2047.

D.12.7.9 allreal

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur.lib\]](#), page 2044).

Usage: `allreal(p);`

Return: int: 1 if and only if all the roots of `p` are real, 0 otherwise

Example:

```
LIB "rootsur.lib";
ring r = 0,x,dp;
poly p = (x+2)*(x-1)*(x-5);
allreal(p);
↦ 1
p = p*(x2+1);
allreal(p);
↦ 0
```

See also: [Section D.12.7.7 \[allrealst\]](#), page 2046.

D.12.7.10 sturm

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur.lib\]](#), page 2044).

Usage: `sturm(p,a,b);` poly `p`, number `a,b`

Return: int: the number of real roots of `p` in $(a,b]$

Assume: `p` is a univariate polynomial with rational coefficients,
 `a, b` are rational numbers with $a < b$

Example:

```
LIB "rootsur.lib";
ring r = 0,x,dp;
poly p = (x+2)*(x-1)*(x-5);
sturm(p,-3,6);
↦ 3
p = p*(x2+1);
sturm(p,-3,6);
↦ 3
```

```

p = p*(x+2);
sturm(p,-3,6);
↦ 3

```

See also: [Section D.12.7.9 \[allreal\]](#), page 2047; [Section D.12.7.7 \[allrealst\]](#), page 2046; [Section D.12.7.12 \[sturmha\]](#), page 2048.

D.12.7.11 sturmseq

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur.lib\]](#), page 2044).

Usage: `sturmseq(p);` p poly

Return: list: a Sturm sequence of p

Assume: p is a univariate polynomial with rational coefficients

Theory: The Sturm sequence of p (also called remainder sequence) is the sequence beginning with p, p' and goes on with the negative part of the remainder of the two previous polynomials, until the remainder is zero.

See: Basu, Pollack, Roy, Algorithms in Real Algebraic Geometry, Springer, 2003.

Example:

```

LIB "rootsur.lib";
ring r = 0,(z,x),dp;
poly p = x5-3x4+12x3+7x-153;
sturmseq(p);
↦ [1]:
↦ x5-3x4+12x3+7x-153
↦ [2]:
↦ x4-12/5x3+36/5x2+7/5
↦ [3]:
↦ -x3-9/7x2-5/3x+317/7
↦ [4]:
↦ -x2-756/151x+2433/151
↦ [5]:
↦ x-514191/177889
↦ [6]:
↦ 1

```

See also: [Section D.12.7.10 \[sturm\]](#), page 2047; [Section D.12.7.13 \[sturmhaseq\]](#), page 2049.

D.12.7.12 sturmha

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur.lib\]](#), page 2044).

Usage: `sturmha(p,a,b);` poly p, number a,b

Return: int: the number of real roots of p in (a,b) (using a Sturm-Habicht sequence)

Example:

```

LIB "rootsur.lib";
ring r = 0,x,dp;
poly p = (x+2)*(x-1)*(x-5);
sturmha(p,-3,6);
↦ 3
p = p*(x2+1);
sturmha(p,-3,6);

```

↪ 3

See also: [Section D.12.7.9 \[allreal\]](#), page 2047; [Section D.12.7.10 \[sturm\]](#), page 2047.

D.12.7.13 sturmhaseq

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur.lib\]](#), page 2044).

Usage: `sturmhaseq(P)`; P poly.

Return: list: the non-zero polynomials of the Sturm-Habicht sequence of P

Assume: P is a univariate polynomial.

Theory: The Sturm-Habicht sequence (also subresultant sequence) is closely related to the Sturm sequence, but behaves better with respect to the size of the coefficients. It is defined via subresultants. See: Basu, Pollack, Roy, *Algorithms in Real Algebraic Geometry*, Springer, 2003.

Example:

```
LIB "rootsur.lib";
ring r = 0,x,dp;
poly p = x5-x4+x-3/2;
list l = sturmhaseq(p);
l;
↪ [1]:
↪ 132949/16

↪ -25x-332
↪ [3]:
↪ -16x2+42x-24
↪ [4]:
↪ 4x3-20x+73/2
↪ [5]:
↪ 5x4-4x3+1
↪ [6]:
↪ x5-x4+x-3/2
```

See also: [Section D.12.7.10 \[sturm\]](#), page 2047; [Section D.12.7.12 \[sturmha\]](#), page 2048; [Section D.12.7.11 \[sturmseq\]](#), page 2048.

D.12.7.14 reverse

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur.lib\]](#), page 2044).

Usage: `reverse(l)`; l list

Return: list: l reversed.

Example:

```
LIB "rootsur.lib";
ring r = 0,x,dp;
list l = 1,2,3,4,5;
list rev = reverse(l);
l;

```

D.12.7.15 nrroots

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur.lib\]](#), page 2044).

Usage: `nrroots(p); poly p`

Return: `int`: the number of real roots of `p`

Example:

```

LIB "rootsur.lib";
ring r = 0,x,dp;
poly p = (x+2)*(x-1)*(x-5);
nrroots(p);
↪ 3
p = p*(x2+1);
nrroots(p);
↪ 3

```

D.12.7.16 isparam

Procedure from library `rootsur.lib` (see [Section D.12.7 \[rootsur.lib\]](#), page 2044).

Usage: `isparam(ideal/module/poly/list);`

Return: `int`: 0 if the argument has non-parametric coefficients and 1 if it has parametric coefficients

Example:

```

LIB "rootsur.lib";
ring r = 0,x,dp;
isparam(2x3-56x+2);
↪ 0
ring s = (0,a,b,c),x,dp;
isparam(2x3-56x+2);

```

```

    ↦ 0
    isparam(2x3-56x+abc);
    ↦ 1

```

D.13 Tropical Geometry

D.13.1 cimonom_lib

Library: cimonom.lib

Purpose: Determines if the toric ideal of an affine monomial curve is a complete intersection

Authors: I.Bermejo, ibermejo@ull.es
 I.Garcia-Marco, iggarcia@ull.es
 J.-J.Salazar-Gonzalez, jjsalaza@ull.es

Overview: A library for determining if the toric ideal of an affine monomial curve is a complete intersection with NO NEED of computing explicitly a system of generators of such ideal. It also contains procedures to obtain the minimum positive multiple of an integer which is in a semigroup of positive integers. The procedures are based on a paper by Isabel Bermejo, Ignacio Garcia and Juan Jose Salazar-Gonzalez: 'An algorithm to check whether the toric ideal of an affine monomial curve is a complete intersection', Preprint.

Procedures: See also: [Section C.6.4 \[Integer programming\]](#), page 784.

D.13.1.1 BelongSemig

Procedure from library `cimonom.lib` (see [Section D.13.1 \[cimonom.lib\]](#), page 2051).

Usage: BelongSemig (n,v[,sup]); n bigint, v and sup intvec

Return: In the default form, it returns 1 if n is in the semigroup generated by the elements of v or 0 otherwise. If the argument sup is added and in case n belongs to the semigroup generated by the elements of v, it returns a monomial in the variables $\{x(i) \mid i \text{ in sup}\}$ of degree n if we set $\deg(x(\text{sup}[j])) = v[j]$.

Assume: v and sup positive integer vectors of same size, sup has no repeated entries, x(i) has to be an indeterminate in the current ring for all i in sup.

Example:

```

LIB "cimonom.lib";
ring r=0,x(1..5),dp;
int a = 125;
intvec v = 13,17,51;
intvec sup = 2,4,1;
BelongSemig(a,v,sup);
↦ x(2)^7*x(4)^2
BelongSemig(a,v);
↦ 1

```

D.13.1.2 MinMult

Procedure from library `cimonom.lib` (see [Section D.13.1 \[cimonom.lib\], page 2051](#)).

Usage: MinMult (a, b); a integer, b integer vector.

Return: an integer k, the minimum positive integer such that ka belongs to the semigroup generated by the integers in b.

Assume: a is a positive integer, b is a positive integers vector.

Example:

```
LIB "cimonom.lib";
"int a = 46;";
↪ int a = 46;
"intvec b = 13,17,59;";
↪ intvec b = 13,17,59;
"MinMult(a,b);";
↪ MinMult(a,b);
int a = 46;
intvec b = 13,17,59;
MinMult(a,b);
↪ 3
"// 3*a = 8*b[1] + 2*b[2]"
```

D.13.1.3 CompInt

Procedure from library `cimonom.lib` (see [Section D.13.1 \[cimonom.lib\], page 2051](#)).

Usage: CompInt(d); d intvec.

Return: 1 if the toric ideal $I(d)$ is a complete intersection or 0 otherwise.

Assume: d is a vector of positive integers.

Note: If `printlevel > 0`, additional info is displayed in case $I(d)$ is a complete intersection: if `printlevel >= 1`, it displays a minimal set of generators of the toric ideal formed by quasihomogeneous binomials. Moreover, if `printlevel >= 2` and $\gcd(d) = 1$, it also shows the Frobenius number of the semigroup generated by the elements in d.

Example:

```
LIB "cimonom.lib";
printlevel = 0;
intvec d = 14,15,10,21;
CompInt(d);
↪ 1
printlevel = 3;
d = 36,54,125,150,225;
CompInt(d);
↪ // Toric ideal:
↪ id[1]=-x(1)^3+x(2)^2
↪ id[2]=-x(4)^3+x(5)^2
↪ id[3]=-x(3)^3+x(4)*x(5)
↪ id[4]=-x(1)^11*x(2)+x(4)^3
↪ // Frobenius number of the numerical semigroup:
↪ 793
↪ 1
```

```

d = 45,70,75,98,147;
CompInt(d);
↦ 0

```

D.13.2 gfan.lib

Library: gfan.lib

Purpose: Interface to gfan and gfanlib for computations in convex geometry

Authors: Anders N. Jensen, email: jensen@imf.au.dk
 Yue Ren, email: ren@mathematik.uni-kl.de
 Frank Seelisch

Procedures:

D.13.2.1 fullSpace

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: fullSpace(n); n int

Return: cone, the ambient space of dimension n

Example:

```

LIB "gfan.lib";
cone c = fullSpace(2);
generatorsOfLinealitySpace(c);
↦ -1, 0,
↦ 0, -1

```

D.13.2.2 origin

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: origin(n); n int

Return: cone, the origin in an ambient space of dimension n

Example:

```

LIB "gfan.lib";
cone c = origin(2);
equations(c);
↦ 1,0,
↦ 0,1

```

D.13.2.3 positiveOrthant

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: positiveOrthant(n); n int

Return: cone, the positive orthant of dimension n

Example:

```

LIB "gfan.lib";
cone c = positiveOrthant(2);
rays(c);
↦ 1,0,
↦ 0,1

```

D.13.2.4 ambientDimension

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `ambientDimension(c)`; `c` cone
 `ambientDimension(f)`; `f` fan
 `ambientDimension(p)`; `p` polytope

Return: `int`, the dimension of the ambient space the input lives in

Example:

```
LIB "gfan.lib";
intmat M1[2][2]=
1,0,
0,1;
cone c1=coneViaPoints(M1);
ambientDimension(c1);
↪ 2
intmat M2[2][3]=
1,0,0,
0,1,0;
cone c2=coneViaPoints(M2);
ambientDimension(c2);
↪ 3
fan f = emptyFan(3);
ambientDimension(f);
↪ 3
```

D.13.2.5 canonicalizeCone

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `canonicalizeCone(c)`; `c` cone

Return: cone, a unique representation of the cone `c`

Example:

```
LIB "gfan.lib";
intmat M[5][3]=
8,1,9,
9,2,4,
0,6,2,
8,8,8,
0,9,5;
cone c=coneViaInequalities(M);
c;

```

D.13.2.6 codimension

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `codimension(c); c cone`
 `codimension(f); f fan`
 `codimension(p); p polytope`

Return: `int`, the codimension of the input

Example:

```

LIB "gfan.lib";
intmat M1[1][2]=
1,0;
cone c1=coneViaPoints(M1);
codimension(c1);
↳ 1
intmat M2[2][2]=
1,0,
0,1;
cone c2=coneViaPoints(M2);
codimension(c2);
↳ 0
fan f = emptyFan(2);
codimension(f);
↳ -1
insertCone(f,c1);
codimension(f);
↳ 1
insertCone(f,c2);

```

```
codimension(f);
↳ 0
```

D.13.2.7 coneViaPoints

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `coneViaPoints(HL);` intmat HL
 `coneViaPoints(HL,L);` intmat HL, intmat L
 `coneViaPoints(HL,L,flags);` intmat HL, intmat L, int flags

Return: cone

Purpose: cone generated by half lines generated by the row vectors of HL and (if stated) by lines generated by the row vectors of L; flags may range between 0,...,3 defining an upper and lower bit ($0=0*2+0$, $1=0*2+1$, $2=1*2+0$, $3=1*2+1$),
 if upper bit is 1, then program assumes that each row vector in HL generates a ray of the cone,
 if lower bit is 1, then program assumes that the span of the row vectors of L is the lineality space of the cone,
 if either bit is 0, then program computes the information itself.

Example:

```
LIB "gfan.lib";
// Let's define a cone in R^3 generated by the following half lines:
intmat HL[5][3]=
1,0, 0,
-1,0, 0,
0,1, 1,
0,1,-1,
0,0, 1;
cone c=coneViaPoints(HL);
c;
↳ AMBIENT_DIM
↳ 3
↳ FACETS
↳ 0,1,0,
↳ 0,1,1
↳ LINEAR_SPAN
↳
↳
kill HL,c;
// Note that (1,0,0) and (-1,0,0) form a line, hence also possible:
intmat HL[3][3]=
0,1, 1,
0,1,-1,
0,0, 1;
intmat L[1][3]=
1,0,0;
cone c=coneViaPoints(HL,L);
c;
↳ AMBIENT_DIM
↳ 3
↳ FACETS
```

```

⇒ 0,1,0,
⇒ 0,1,1
⇒ LINEAR_SPAN
⇒
⇒
kill HL,L,c;
// lineality space is exactly Lin(1,0,0)
intmat HL[3][3]=
0,1, 1,
0,1,-1,
0,0, 1;
intmat L[1][3]=
1,0,0;
cone c=coneViaPoints(HL,L,1);
c;
⇒ AMBIENT_DIM
⇒ 3
⇒ FACETS
⇒ 0,1,0,
⇒ 0,1,1
⇒ LINEAR_SPAN
⇒
⇒
kill HL,L,c;
// and that (0,1,-1), (0,1,1) generate rays
intmat HL[3][3]=
0,1, 1,
0,1,-1;
intmat L[1][3]=
1,0,0;
cone c=coneViaPoints(HL,L,1);
c;
⇒ AMBIENT_DIM
⇒ 3
⇒ FACETS
⇒ 0,1,-1,
⇒ 0,1, 1
⇒ LINEAR_SPAN
⇒
⇒
kill HL,L,c;
// and that (0,1,-1), (0,1,1) generate rays
intmat HL[3][3]=
0,1, 1,
0,1,-1;
intmat L[1][3]=
1,0,0;
cone c=coneViaPoints(HL,L,3);
c;
⇒ AMBIENT_DIM
⇒ 3
⇒ FACETS
⇒ 0,1,-1,

```

```

⇒ 0,1, 1
⇒ LINEAR_SPAN
⇒
⇒

```

D.13.2.8 coneViaInequalities

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `coneViaInequalities(IE); intmat IE`
 `coneViaInequalities(IE,E); intmat IE, intmat E`
 `coneViaInequalities(IE,E,flags); intmat IE, intmat E, int flags`

Return: `cone`

Purpose: cone consisting of all points x , such that $IE \cdot x \geq 0$ in each component and (if stated) $E \cdot x = 0$;
 inequalities and (if stated) equations will be transformed, getting rid of redundancies;
 flags may range between 0,...,3 defining an upper and lower bit ($0=0 \cdot 2+0$, $1=0 \cdot 2+1$,
 $2=1 \cdot 2+0$, $3=1 \cdot 2+1$),
 if higher bit is 1, then program assumes each inequality yields a facet, if lower bit is 1,
 then program assumes the kernel of E is the span of the cone, if either bit is 0, then
 program computes the information itself.

Example:

```

LIB "gfan.lib";
// Let's define a cone in R^3 given by the following inequalities:
intmat IE[6][3]=
1,3,5,
1,5,3,
0,1,-1,
0,1,1,
1,0,0,
-1,0,0;
cone c=coneViaInequalities(IE);
c;
⇒ AMBIENT_DIM
⇒ 3
⇒ INEQUALITIES
⇒ 0,1,-1,
⇒ 0,1, 1,
⇒ 1,3, 5,
⇒ 1,5, 3
⇒ LINEAR_SPAN
⇒ -1,0,0
⇒
// Note that the last two inequalities yield  $x_1 = 0$ , hence also possible:
intmat IE[4][3]=
⇒ // ** redefining IE (intmat IE[4][3]=) ./examples/coneViaInequalities.sin\
g:13
0,1,-1,
0,1,1;
intmat E[1][3]=
1,0,0;

```

```

cone c=coneViaInequalities(IE,E);
⇒ // ** redefining c (cone c=coneViaInequalities(IE,E);) ./examples/coneVia\
  Inequalities.sing:18
c;
⇒ AMBIENT_DIM
⇒ 3
⇒ INEQUALITIES
⇒ 0,1,-1,
⇒ 0,1, 1
⇒ LINEAR_SPAN
⇒ 1,0,0
⇒
// each inequalities gives rise to a facet
intmat IE[2][3]=
⇒ // ** redefining IE (intmat IE[2][3]=) ./examples/coneViaInequalities.sin\
  g:21
0,1,-1,
0,1,1;
intmat E[1][3]=
⇒ // ** redefining E (intmat E[1][3]=) ./examples/coneViaInequalities.sing:\
  24
1,0,0;
cone c=coneViaInequalities(IE,E,1);
⇒ // ** redefining c (cone c=coneViaInequalities(IE,E,1);) ./examples/coneV\
  iaInequalities.sing:26
c;
⇒ AMBIENT_DIM
⇒ 3
⇒ INEQUALITIES
⇒ 0,1,-1,
⇒ 0,1, 1
⇒ LINEAR_SPAN
⇒ 1,0,0
⇒
// and the kernel of E is the span of the cone
intmat IE[2][3]=
⇒ // ** redefining IE (intmat IE[2][3]=) ./examples/coneViaInequalities.sin\
  g:29
0,1,-1,
0,1,1;
intmat E[1][3]=
⇒ // ** redefining E (intmat E[1][3]=) ./examples/coneViaInequalities.sing:\
  32
1,0,0;
cone c=coneViaInequalities(IE,E,3);
⇒ // ** redefining c (cone c=coneViaInequalities(IE,E,3);) ./examples/coneV\
  iaInequalities.sing:34
c;
⇒ AMBIENT_DIM
⇒ 3
⇒ FACETS
⇒ 0,1,-1,
⇒ 0,1, 1

    ↪ LINEAR_SPAN
    ↪ 1,0,0
    ↪

```

D.13.2.9 coneLink

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `coneLink(c,w)`; `c` cone, `w` intvec/bigintmat

Return: cone, the link of `c` around `w`

Example:

```

LIB "gfan.lib";
intmat M[3][3]=
1,0,0,
0,1,0,
0,0,1;
cone c=coneViaPoints(M);
intvec v=1,0,0;
cone cv=coneLink(c,v);
rays(cv);
↪ 0,1,0,
↪ 0,0,1
generatorsOfLinealitySpace(cv);
↪ -1,0,0
intvec w=1,1,1;
cone cw=coneLink(c,w);
rays(cw);
↪
generatorsOfLinealitySpace(cw);
↪ -1, 0, 0,
↪ 0,-1, 0,
↪ 0, 0,-1

```

D.13.2.10 containsAsFace

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `containsAsFace(c,d)`; `c` cone, `d` cone

Return: 1, if `d` is a face of `c`; 0 otherwise

Example:

```

LIB "gfan.lib";
intmat M[2][2]=
1,0,
0,1;
cone c=coneViaPoints(M);
intmat N1[1][2]=
1,1;
cone d1=coneViaPoints(N1);
containsInSupport(c,d1);
↪ 1
containsAsFace(c,d1);
↪ 0

```

```

intmat N2[1][2]=
0,1;
cone d2=coneViaPoints(N2);
containsInSupport(c,d2);
↳ 1
containsAsFace(c,d2);
↳ 1

```

D.13.2.11 containsInSupport

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `containsInSupport(c,d);` c cone, d cone
 `containsInSupport(c,p);` c cone, p intvec/bigintmat

Return: 1, if d resp. p is contained in c ; 0 otherwise

Example:

```

LIB "gfan.lib";
intmat M[2][2]=
1,0,
0,1;
cone c=coneViaPoints(M);
containsInSupport(c,c);
↳ 1
intmat N1[2][2]=
1,1,
0,1;
cone d1=coneViaPoints(N1);
containsInSupport(c,d1);
↳ 1
intmat N2[2][2]=
1,1,
1,-1;
cone d2=coneViaPoints(N2);
containsInSupport(c,d2);
↳ 0
intvec p1=0,1;
containsInSupport(c,p1);
↳ 1
intvec p2=1,-1;
containsInSupport(c,p2);
↳ 0

```

D.13.2.12 containsPositiveVector

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `containsPositiveVector(c);` c cone

Return: 1, if c contains a vector with only positive entries in its relative interior

Example:

```

LIB "gfan.lib";
intmat M1[2][2]=
1,1,

```

```

1,-1;
cone c1=coneViaPoints(M1);
containsPositiveVector(c1);
 $\mapsto$  1
intmat M2[2][2]=
0,1,
-1,0;
cone c2=coneViaPoints(M2);
containsPositiveVector(c2);
 $\mapsto$  0

```

D.13.2.13 containsRelatively

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `containsRelatively(c,p);` c cone, p intvec/bigintmat

Return: 1 iff the given cone contains the given point in its relative interior; 0 otherwise

Example:

```

LIB "gfan.lib";
intmat M[2][2]=
1,0,
0,1;
cone c=coneViaPoints(M);
intvec p1=1,1;
containsRelatively(c,p1);
 $\mapsto$  1
intvec p2=0,1;
containsRelatively(c,p2);
 $\mapsto$  0

```

D.13.2.14 convexHull

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `convexHull(c1,c2);` c1 cone, c2 cone
`convexHull(c1,p1);` c1 cone, p1 polytope
`convexHull(p1,c1);` p1 cone, c1 polytope
`convexHull(p1,p2);` p1 polytope, p2 polytope

Return: cone resp polytope, the convex hull of its two input objects

Example:

```

LIB "gfan.lib";
intmat M1[2][2]=
1,0,
0,1;
cone c1=coneViaPoints(M1);
intmat M2[2][2]=
1,1,
1,-1;
cone c2=coneViaPoints(M2);
intmat M3[2][2]=
1,0,

```

```

0,-1;
cone c3=coneViaPoints(M3);
cone c12=convexHull(c1,c2);
c12;
⇒ AMBIENT_DIM
⇒ 2
⇒ FACETS
⇒ 1,0,
⇒ 1,1
⇒ LINEAR_SPAN
⇒
⇒
print(rays(c12));
⇒ 1,-1,
⇒ 0, 1
cone c23=convexHull(c2,c3);
c23;
⇒ AMBIENT_DIM
⇒ 2
⇒ FACETS
⇒ 1,-1,
⇒ 1, 0
⇒ LINEAR_SPAN
⇒
⇒
print(rays(c23));
⇒ 0,-1,
⇒ 1, 1
cone c13=convexHull(c1,c3);
c13;
⇒ AMBIENT_DIM
⇒ 2
⇒ FACETS
⇒ 1,0
⇒ LINEAR_SPAN
⇒
⇒
print(rays(c13));
⇒ 1,0

```

D.13.2.15 convexIntersection

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `convexIntersection(c1,c2);` c1 cone, c2 cone
 `convexIntersection(c1,p1);` c1 cone, p1 polytope
 `convexIntersection(p1,c1);` p1 cone, c1 polytope
 `convexIntersection(p1,p2);` p1 polytope, p2 polytope
 `convexIntersection(L);` L list of cones resp polytopes

Return: cone resp polytope, the convex hull of its two input objects

Example:

```
LIB "gfan.lib";
```

```

intmat M1[2][2]=
1,0,
0,1;
cone c1=coneViaPoints(M1);
intmat M2[2][2]=
1,1,
1,-1;
cone c2=coneViaPoints(M2);
intmat M3[2][2]=
1,0,
0,-1;
cone c3=coneViaPoints(M3);
cone c12=convexIntersection(c1,c2);
c12;
⇒ AMBIENT_DIM
⇒ 2
⇒ FACETS
⇒ 0, 1,
⇒ 1,-1
⇒ LINEAR_SPAN
⇒
⇒
print(rays(c12));
⇒ 1,0,
⇒ 1,1
cone c23=convexIntersection(c2,c3);
c23;
⇒ AMBIENT_DIM
⇒ 2
⇒ FACETS
⇒ 0,-1,
⇒ 1, 1
⇒ LINEAR_SPAN
⇒
⇒
print(rays(c23));
⇒ 1, 0,
⇒ 1,-1
cone c13=convexIntersection(c1,c3);
c13;
⇒ AMBIENT_DIM
⇒ 2
⇒ FACETS
⇒ 1,0
⇒ LINEAR_SPAN
⇒ 0,1
⇒
print(rays(c13));
⇒ 1,0

```

D.13.2.16 dimension

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `dimension(c); c cone`
 `dimension(f); f fan`
 `dimension(p); p polytope`

Return: `int`, the dimension of the input

Example:

```
LIB "gfan.lib";
intmat M1[1][2]=
1,0;
cone c1=coneViaPoints(M1);
dimension(c1);
↪ 1
intmat M2[2][2]=
1,0,
0,1;
cone c2=coneViaPoints(M2);
dimension(c2);
↪ 2
fan f = emptyFan(2);
dimension(f);
↪ -1
insertCone(f,c1);
dimension(f);
↪ 1
insertCone(f,c2);
dimension(f);
↪ 2
```

D.13.2.17 dualCone

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `dualCone(c); c cone`

Return: `cone`, the dual of `c`

Example:

```
LIB "gfan.lib";
intmat M1[2][2]=
1,0,
0,1;
cone c1=coneViaPoints(M1);
cone d1=dualCone(c1);
d1;
↪ AMBIENT_DIM
↪ 2
↪ INEQUALITIES
↪ 0,1,
↪ 1,0
↪ LINEAR_SPAN
↪
↪
print(rays(d1));
↪ 1,0,
```

```

⇒ 0,1
intmat M2[2][2]=
1,1,
0,1;
cone c2=coneViaPoints(M2);
cone d2=dualCone(c2);
d2;
⇒ AMBIENT_DIM
⇒ 2
⇒ INEQUALITIES
⇒ 0,1,
⇒ 1,1
⇒ LINEAR_SPAN
⇒
⇒
print(rays(d2));
⇒ 1,0,
⇒ -1,1

```

D.13.2.18 equations

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `equations(c)`; `c` cone
 `equations(p)`; `p` polytope

Return: `bigintmat`, defining equations of `c` resp `p`

Note: neither unique nor complete, unless `c` resp `p` in canonical form

Example:

```

LIB "gfan.lib";
intmat M1[2][2]=
1,0,
0,1;
cone c1=coneViaPoints(M1);
bigintmat E1=equations(c1);
print(E1);
⇒
intmat M2[1][2]=
1,0;
cone c2=coneViaPoints(M2);
bigintmat E2=equations(c2);
print(E2);
⇒ 0,-1

```

D.13.2.19 faceContaining

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `faceContaining(c,w)`; `c` cone, `w` intvec/bigintmat

Assume: `containsInSupport(c,w)==1`

Return: cone, the face of `c` containing `w` in its relative interior

Example:

```

LIB "gfan.lib";
intmat M[2][2]=
1,0,
0,1;
cone c=coneViaPoints(M);
faceContaining(c,intvec(1,0));
⇒ AMBIENT_DIM
⇒ 2
⇒ INEQUALITIES
⇒ 1,0
⇒ LINEAR_SPAN
⇒ 0,1
⇒
faceContaining(c,intvec(0,1));
⇒ AMBIENT_DIM
⇒ 2
⇒ INEQUALITIES
⇒ 0,1
⇒ LINEAR_SPAN
⇒ 1,0
⇒
faceContaining(c,intvec(1,1));
⇒ AMBIENT_DIM
⇒ 2
⇒ INEQUALITIES
⇒ 0,1,
⇒ 1,0
⇒ LINEAR_SPAN
⇒
⇒
faceContaining(c,intvec(0,0));
⇒ AMBIENT_DIM
⇒ 2
⇒ INEQUALITIES
⇒
⇒ LINEAR_SPAN
⇒ 1,0,
⇒ 0,1
⇒

```

D.13.2.20 facets

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `facets(c);` c cone
 `facets(p);` p polytope

Return: bigintmat, the facets of c resp p

Example:

```

LIB "gfan.lib";
intmat M1[2][2]=
1,0,
0,1;

```

```

cone c1=coneViaPoints(M1);
bigintmat F1=facets(c1);
print(F1);
↳ 0,1,
↳ 1,0
intmat M2[2][2]=
1,1,
0,-1;
cone c2=coneViaPoints(M2);
bigintmat F2=facets(c2);
print(F2);
↳ 1,-1,
↳ 1, 0

```

D.13.2.21 generatorsOfLinealitySpace

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `generatorsOfLinealitySpace(c); c cone`

Return: `bigintmat`, generators of the lineality space of `c`

Example:

```

LIB "gfan.lib";
intmat M[5][3]=
1,0,0,
0,1,0,
0,0,1,
-1,0,0,
0,-1,0;
cone c=coneViaPoints(M);
bigintmat L=generatorsOfLinealitySpace(c);
print(L);
↳ -1, 0,0,
↳ 0,-1,0

```

D.13.2.22 generatorsOfSpan

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `generatorsOfSpan(c); c cone`

Return: `bigintmat`, generators of the span of `c`

Example:

```

LIB "gfan.lib";
intmat M[3][5]=
1,0,0,0,0,
0,1,0,0,0,
0,0,1,0,0;
cone c=coneViaPoints(M);
bigintmat S=generatorsOfSpan(c);
print(S);
↳ -1, 0, 0,0,0,
↳ 0,-1, 0,0,0,
↳ 0, 0,-1,0,0

```

D.13.2.23 getLinearForms

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `getLinearForms(c);` c cone
 `getLinearForms(p);` p polytope

Return: `bigintmat`, linear forms previously stored in c resp p

Example:

```
LIB "gfan.lib";
intmat M[2][3]=
-1,0,0,
0,-1,0;
cone c=coneViaPoints(M);
getLinearForms(c);
↦
intvec v=1,1,1;
setLinearForms(c,v);
getLinearForms(c);
↦ 1,1,1
```

D.13.2.24 getMultiplicity

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `getMultiplicity(c);` c cone
 `getMultiplicity(p);` p polytope

Return: `bigint`, 1 or a multiplicity previously stored in c resp p

Example:

```
LIB "gfan.lib";
intmat M[2][3]=
-1,0,0,
0,-1,0;
cone c=coneViaPoints(M);
getMultiplicity(c);
↦ 1
setMultiplicity(c,3);
getMultiplicity(c);
↦ 3
```

D.13.2.25 inequalities

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `inequalities(c);` c cone
 `inequalities(p);` p polytope

Return: `bigintmat`, the inequalities of c resp p

Note: neither unique nor irredundant, unless c resp p in canonical form

Example:

```

LIB "gfan.lib";
intmat M1[2][2]=
1,0,
0,1;
cone c1=coneViaPoints(M1);
bigintmat I1=inequalities(c1);
print(I1);
↪ 0,1,
↪ 1,0
intmat M2[2][2]=
1,1,
0,-1;
cone c2=coneViaPoints(M2);
bigintmat I2=inequalities(c2);
print(I2);
↪ 1,-1,
↪ 1, 0

```

D.13.2.26 isFullSpace

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `isFullSpace(c)`; c cone

Return: 1, if c is the entire ambient space; 0 otherwise

Example:

```

LIB "gfan.lib";
cone c1;
isFullSpace(c1);
↪ 1
intmat M2[2][2]=
1,0,
0,1;
cone c2=coneViaPoints(M2);
isFullSpace(c2);
↪ 0
intmat M3[4][2]=
1,0,
0,1,
-1,0,
0,-1;
cone c3=coneViaPoints(M3);
isFullSpace(c3);
↪ 1

```

D.13.2.27 isOrigin

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `isOrigin(c)`; c cone

Return: 1, if c is the origin; 0 otherwise

Example:

```

LIB "gfan.lib";
cone c1;
isOrigin(c1);
 $\mapsto$  1
intmat M2[2][2]=
1,0,
0,1;
cone c2=coneViaPoints(M2);
isOrigin(c2);
 $\mapsto$  0
intmat M3[4][2]=
1,0,
0,1,
-1,0,
0,-1;
cone c3=coneViaPoints(M3);
isOrigin(c3);
 $\mapsto$  0

```

D.13.2.28 isSimplicial

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `isSimplicial(c)`; `c` cone
 `isSimplicial(f)`; `f` fan

Return: 1, if `c` resp `f` is simplicial; 0 otherwise

Example:

```

LIB "gfan.lib";
intmat M1[3][3]=
1,0,0,
0,1,0,
0,0,1;
cone c1=coneViaPoints(M1);
isSimplicial(c1);
 $\mapsto$  1
intmat M2[4][3]=
1,0,0,
0,1,0,
0,0,1,
1,1,-1;
cone c2=coneViaPoints(M2);
isSimplicial(c2);
 $\mapsto$  0
/*****/
fan f=emptyFan(3);
isSimplicial(f);
 $\mapsto$  1
intmat N1[3][3]=
1,0,0,
0,1,0,
0,0,1;
cone d1=coneViaPoints(N1);

```

```

insertCone(f,d1);
isSimplicial(f);
 $\mapsto$  1
intmat N2[4][3]=
1,0,0,
0,1,0,
1,0,-1,
0,1,-1;
cone d2=coneViaPoints(N2);
insertCone(f,d2);
isSimplicial(f);
 $\mapsto$  0

```

D.13.2.29 linealityDimension

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `linealityDimension(c); c cone`
 `linealityDimension(f); f fan`

Return: `int`, the dimension of the lineality space of `c` resp `f`

Example:

```

LIB "gfan.lib";
intmat M1[3][3]=
1,0,0,
0,1,0,
0,0,1;
cone c1=coneViaPoints(M1);
linealityDimension(c1);
 $\mapsto$  0
intmat M2[4][3]=
1,0,0,
0,1,0,
0,0,1,
-1,0,0;
cone c2=coneViaPoints(M2);
linealityDimension(c2);
 $\mapsto$  1

```

D.13.2.30 linealitySpace

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `linealitySpace(c); c cone`

Return: `cone`, the lineality space of `c`

Example:

```

LIB "gfan.lib";
intmat M1[3][3]=
1,0,0,
0,1,0,
0,0,1;
cone c1=coneViaPoints(M1);
cone l1=linealitySpace(c1);

```

```

l1;
↳ AMBIENT_DIM
↳ 3
↳ INEQUALITIES
↳
↳ LINEAR_SPAN
↳ 1,0,0,
↳ 0,1,0,
↳ 0,0,1
↳
intmat M2[4][3]=
1,0,0,
0,1,0,
0,0,1,
-1,0,0;
cone c2=coneViaPoints(M2);
cone l2=linealitySpace(c2);
l2;
↳ AMBIENT_DIM
↳ 3
↳ INEQUALITIES
↳
↳ LINEAR_SPAN
↳ 0,1,0,
↳ 0,0,1
↳

```

D.13.2.31 negatedCone

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `negatedCone(c); c cone`

Return: `cone`, the negative of `c`

Example:

```

LIB "gfan.lib";
intmat M[2][2]=
1,0,
0,1;
cone c=coneViaPoints(M);
cone cn=negatedCone(c);
print(rays(cn));
↳ -1, 0,
↳ 0, -1

```

D.13.2.32 polytopeViaInequalities

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `polytopeViaInequalities(EV [, E [, flags]]); intmat EV,E, int flags`

Return: `polytope` consisting of all points x , such that $IE^*x \geq 0$ in each component and (if stated) $E^*x = 0$;
`flags` may range between 0,...,3 defining an upper and lower bit ($0=0*2+0$, $1=0*2+1$,

$2=1*2+0$, $3=1*2+1$),
 if higher bit is 1, then program assumes each inequality yields a facet, if lower bit is 1,
 then program assumes the kernel of E is the span of the cone, if either bit is 0, then
 program computes the information itself.

Example:

```
LIB "gfan.lib";
intmat IE[2][3]=
1,0,0,
0,1,0;
intmat E[1][3]=
0,0,1;
polytope p=polytopeViaInequalities(IE,E);
p;
↳ AMBIENT_DIM
↳ 2
↳ INEQUALITIES
↳ 0,1,0,
↳ 1,0,0
↳ EQUATIONS
↳ 0,0,1
↳
```

D.13.2.33 polytopeViaPoints

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `polytopeViaPoints(V [, flags]);` intmat V, int flags

Return: polytope which is the intersection of the cone generated by the row vectors of V with the hyperplane, in which the first coordinate equals 1; flags may be 0 or 1, if flags is 1, then program assumes that each row vector of M generates a ray in the cone, if flags is 0, then program computes that information itself

Example:

```
LIB "gfan.lib";
// This is a polytope in R^2 generated by (0,0), (1,0), (0,1), (0,0);
intmat V[4][3]=
1,0,0,
1,1,0,
1,0,1,
1,1,1;
polytope p1=polytopeViaPoints(V);
p1;
↳ AMBIENT_DIM
↳ 2
↳ INEQUALITIES
↳ 0, 0, 1,
↳ 0, 1, 0,
↳ 1,-1, 0,
↳ 1, 0,-1
↳ EQUATIONS
↳
↳
```

```

// This is a polytope in R^2 generated by (1/2,2/3), (3/4,4/5), (5/6,6/7):
intmat V[3][3]=
↳ // ** redefining V (intmat V[3][3]=) ./examples/polytopeViaPoints.sing:11
6,3,4,
20,15,16,
42,35,36;
polytope p2=polytopeViaPoints(V);
p2;
↳ AMBIENT_DIM
↳ 2
↳ INEQUALITIES
↳ -10,-24, 35,
↳ -6, -8, 15,
↳ 8, 12,-21
↳ EQUATIONS
↳
↳
// This polytope is the positive orthant in R^2:
// (0,1,0) and (0,0,1) imply that the polytope is unbounded in that direction
intmat V[3][3]=
↳ // ** redefining V (intmat V[3][3]=) ./examples/polytopeViaPoints.sing:19
1,0,0,
0,1,0,

↳
↳

```

D.13.2.34 quotientLatticeBasis

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `quotientLatticeBasis(c);` c cone

Return: `bigintmat`, a basis of \mathbb{Z}^n intersected with the span of c modulo \mathbb{Z}^n intersected with the lineality space of c

Example:

```

LIB "gfan.lib";
intmat M[3][2]=
1,0,
0,1,
-1,0;
cone c=coneViaPoints(M);
bigintmat Q=quotientLatticeBasis(c);
print(Q);
↳ 0,1

```

D.13.2.35 randomPoint

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `randomPoint(c); c cone`
 `randomPoint(c,b); c cone, b int`

Return: `bigintmat`, a random point in the relative interior of `c`

Note: returns a weighted sum over all its rays
 if `b` is given and `b>0`, only chooses weights between 1 and `b`

Example:

```
LIB "gfan.lib";
intmat M[2][2]=
1,0,
0,1;
cone c=coneViaPoints(M);
bigintmat Q=randomPoint(c);
print(Q);
↪ 1335380034,380636641
bigintmat P=randomPoint(c,5);
print(P);
↪ 4,4
```

D.13.2.36 rays

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `rays(c); c cone`

Return: `bigintmat`, generators of the rays of `c`, orthogonal to its lineality space

Example:

```
LIB "gfan.lib";
intmat M1[2][2]=
1,0,
0,1;
cone c1=coneViaPoints(M1);
bigintmat R1=rays(c1);
print(R1);
↪ 1,0,
↪ 0,1
intmat M2[3][2]=
1,0,
0,1,
-1,0;
cone c2=coneViaPoints(M2);
bigintmat R2=rays(c2);
print(R2);
↪ 0,1
```

D.13.2.37 relativeInteriorPoint

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `relativeInteriorPoint(c); c cone`

Return: bigintmat, a point in the relative interior of c

Note: not unique, unless c is in its canonical form

Example:

```
LIB "gfan.lib";
intmat M1[2][2]=
1,0,
0,1;
cone c1=coneViaPoints(M1);
relativeInteriorPoint(c1);
↦ 1,1
intmat M2[2][2]=
1,0,
1,1;
cone c2=coneViaPoints(M2);
relativeInteriorPoint(c2);
↦ 2,1
```

D.13.2.38 semigroupGenerator

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `semigroupGenerator(c);` c cone

Return: bigintmat, the generator of Z^n intersected with c modulo Z^n intersected with the lineality space of c

Assume: `dimension(c) == linealityDimension(c)+1`

Example:

```
LIB "gfan.lib";
intmat M[3][2]=
1,0,
0,1,
-1,0;
cone c=coneViaPoints(M);
semigroupGenerator(c);
↦ 0,1
```

D.13.2.39 setLinearForms

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `setLinearForms(c,v);` c cone, v intvec
`setLinearForms(p,v);` p polytope, v intvec

Return: none, stores linear forms in c resp p

Example:

```
LIB "gfan.lib";
intmat M[2][3]=
-1,0,0,
0,-1,0;
cone c=coneViaPoints(M);
getLinearForms(c);
↦
```

```

intvec v=1,1,1;
setLinearForms(c,v);
getLinearForms(c);
↦ 1,1,1

```

D.13.2.40 setMultiplicity

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `setMultiplicity(c,m)`; `c` cone, `m` int
 `setMultiplicity(p,m)`; `p` polytope, `m` int

Return: none, stores a multiplicity in `c` resp `p`

Example:

```

LIB "gfan.lib";
intmat M[2][3]=
-1,0,0,
0,-1,0;
cone c=coneViaPoints(M);
getMultiplicity(c);
↦ 1
setMultiplicity(c,3);
getMultiplicity(c);
↦ 3

```

D.13.2.41 span

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `span(c)`; `c` cone

Return: `bigintmat`, unique irredundant equations of `c`

Note: the name 'span' was chosen to be in line with polymake's nomenclature

Example:

```

LIB "gfan.lib";
intmat M[3][5]=
1,0,0,0,0,
0,1,0,0,0,
0,0,1,0,0;
cone c=coneViaPoints(M);
bigintmat Eq=span(c);
print(Eq);
↦ 0,0,0,-1, 0,
↦ 0,0,0, 0,-1

```

D.13.2.42 uniquePoint

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `uniquePoint(c)`; `c` cone

Return: `bigintmat`, a unique point in `c` stable under reflections at coordinate hyperplanes

Example:

```

LIB "gfan.lib";
intmat M1[2][2]=
1,0,
0,1;
cone c1=coneViaPoints(M1);
uniquePoint(c1);
↪ 1,1
intmat M2[2][2]=
-1,0,
0,1;
cone c2=coneViaPoints(M2);
uniquePoint(c2);
↪ -1,1

```

D.13.2.43 containsInCollection

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `containsInCollection(f,c)`; f fan, c cone

Return: 1, if f contains c ; 0 otherwise

Example:

```

LIB "gfan.lib";
fan f=emptyFan(2);
intmat M[2][2]=
1,0,
0,1;
cone c=coneViaPoints(M);
containsInCollection(f,c);
↪ 0
insertCone(f,c);
containsInCollection(f,c);
↪ 1

```

D.13.2.44 emptyFan

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `emptyFan(n)`; n int

Return: fan, an empty fan in ambient dimension n

Example:

```

LIB "gfan.lib";
fan f=emptyFan(2);
f;
↪ _application PolyhedralFan
↪ _version 2.2
↪ _type PolyhedralFan
↪
↪ AMBIENT_DIM

D.13.2.45 fanViaCones

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `fanViaCones(L)`; L list
 `fanViaCones(c1[,...,ck])`; c1,...,ck cones

Return: fan, creates a fan generated by the cones in L resp c1,...,ck

Example:

```

LIB "gfan.lib";
intmat M[2][2]=1,0,0,1;
cone c=coneViaPoints(M);
intmat N[2][2]=1,0,0,-1;
cone d=coneViaPoints(N);
fan f=fanViaCones(c,d);

D.13.2.46 fullFan

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `fullFan(n); n int`

Return: `fan`, an full fan in ambient dimension `n`

Example:

```

LIB "gfan.lib";
fan f=fullFan(2);
f;
⇒ _application PolyhedralFan
⇒ _version 2.2
⇒ _type PolyhedralFan

D.13.2.47 fVector

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `fVector(f); f fan`

Return: `bigintmat`, the f-Vector of `f`

Example:

```

LIB "gfan.lib";
fan f=emptyFan(2);
fVector(f);
↳
intmat M[2][2]=1,0,0,1;
cone c=coneViaPoints(M);
insertCone(f,c);
fVector(f);
↳ 1,2,1

```

D.13.2.48 getCone

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `getCone(f,d,i[,m]);` `f` fan, `d` int, `i` int, `m` int

Assume: `d` is between 0 and `ambientDimension(f)`
`i` is between 1 and `numberOfConesOfDimension(f,d,o,m)`

Return: cone, returns in the fan `f` of all cones in dimension `d` the `i`-th cone if `m!=0`, it will enumerate over maximal cones only

Example:

```
LIB "gfan.lib";
intmat M[3][3]=
1,0,0,
0,1,0,
0,0,1;
cone c=coneViaPoints(M);
fan f=emptyFan(3);

⇒ 0,-1,0
⇒
```

D.13.2.49 insertCone

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `insertCone(f,c[,b]);` `f` fan, `c` cone, `b` int

Assume: `isCompatible(f,c)=1`

Return: none, inserts the cone `c` into `f`
if `b=0`, then skips check whether `f` and `c` are compatible

Example:

```
LIB "gfan.lib";
fan f=emptyFan(3);
f;
⇒ _application PolyhedralFan
⇒ _version 2.2
```

D.13.2.50 isCompatible

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `isCompatible(f,c);` f fan, c cone

Return: 1 if f and c live in the same ambient space and
if the intersection of c with any cone of f is a face of each; 0 otherwise

Example:

```

LIB "gfan.lib";
fan f=emptyFan(3);
intmat M1[3][3]=

```

```

1,0,0,
0,1,0,
0,0,1;
cone c1=coneViaPoints(M1);
isCompatible(f,c1);
⇒ 1
insertCone(f,c1);
intmat M2[3][3]=
1,1,1,
1,0,0,
0,1,0;
cone c2=coneViaPoints(M2);
isCompatible(f,c2);
⇒ 0
intmat M3[3][3]=
1,0,0,
0,1,0,
0,0,-1;
cone c3=coneViaPoints(M3);
isCompatible(f,c3);
⇒ 1

```

D.13.2.51 isPure

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `isPure(f); f fan`

Return: 1 if all maximal cones of `f` are of the same dimension 0 otherwise

Example:

```

LIB "gfan.lib";
fan f=fullFan(2);
isPure(f);
⇒ 1
fan g=emptyFan(2);
intmat M1[2][2]=
1,0,
0,1;
cone c1=coneViaPoints(M1);
insertCone(g,c1);
isPure(g);
⇒ 1
intmat M2[1][2]=

D.13.2.52 nmaxcones

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `nmaxcones(f); f fan`

Return: `int`, the number of maximal cones in `f`

Example:

```
LIB "gfan.lib";
fan f=emptyFan(3);
nmaxcones(f);
↪ 0
intmat M1[3][3]=
1,0,0,
0,1,0,
0,0,1;
cone c1=coneViaPoints(M1);
insertCone(f,c1);
nmaxcones(f);
↪ 1
intmat M2[2][3]=
1,0,0,
0,-1,0;
cone c2=coneViaPoints(M2);
insertCone(f,c2);
nmaxcones(f);
↪ 2
```

D.13.2.53 `ncones`

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `ncones(f); f fan`

Return: `int`, the number of cones in `f`

Example:

```
LIB "gfan.lib";
fan f=emptyFan(3);
ncones(f);
↪ 0
intmat M1[3][3]=
1,0,0,
0,1,0,
0,0,1;
cone c1=coneViaPoints(M1);
insertCone(f,c1);
ncones(f);
↪ 8
intmat M2[2][3]=
1,0,0,
0,-1,0;
cone c2=coneViaPoints(M2);
insertCone(f,c2);
ncones(f);
↪ 10
```

D.13.2.54 numberOfConesOfDimension

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `numberOfConesOfDimension(f,d[,m]);` f fan, d int, m int

Assume: d is between 0 and `ambientDimension(f)`

Return: cone, returns in the fan f the number of cones in dimension d if $m \neq 0$, it will only count maximal cones

Example:

```
LIB "gfan.lib";
fan f=emptyFan(3);
ncones(f);
↳ 0
intmat M[3][3]=
1,0,0,
0,1,0,
0,0,1;
cone c=coneViaPoints(M);
insertCone(f,c);
numberOfConesOfDimension(f,0,0);
↳ 1
numberOfConesOfDimension(f,0,1);
↳ 0
numberOfConesOfDimension(f,1,0);
↳ 3
numberOfConesOfDimension(f,0,1);
↳ 0
numberOfConesOfDimension(f,2,0);
↳ 3
numberOfConesOfDimension(f,2,1);
↳ 0
numberOfConesOfDimension(f,3,0);
↳ 1
numberOfConesOfDimension(f,3,1);
↳ 1
```

D.13.2.55 removeCone

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: `removeCone(f,c[,b]);` f fan, c cone, b int

Assume: `containsInCollection(f,c)=1`

Return: none, removes the cone c from f
if $b=0$, skips the check whether c is contained in f

Example:

```
LIB "gfan.lib";
intmat M[2][2]=1,0,0,1;
intmat N[2][2]=1,0,1,-1;
cone c=coneViaPoints(M);
cone d=coneViaPoints(N);
fan f=emptyFan(2);
```

```

D.13.2.56 dualPolytope

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `dualPolytope(p); p polytope`

Return: polytope, the dual of p

Example:

```
LIB "gfan.lib";
intmat M[4][2]=
0,0,
1,0,
0,1,
1,1;
polytope p=polytopeViaPoints(M);

D.13.2.57 newtonPolytope

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: newtonPolytope(f); f poly

Return: polytope, the convex hull of all exponent vectors of f

Example:

```
LIB "gfan.lib";
ring r;
poly f=x+y+z;
polytope p=newtonPolytope(f);
p;
↳ AMBIENT_DIM

```

D.13.2.58 vertices

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\], page 2053](#)).

Usage: vertices(p); p polytope

Return: bigintmat, the vertices of p modulo its lineality space

Example:

```
LIB "gfan.lib";
intmat M[4][3]=
1,0,0,
```

```

1,2,0,
1,0,2,
1,2,2,
1,1,1;
polytope p=polytopeViaPoints(M);
vertices(p);
↦ 1,2,0,
↦ 1,0,0,
↦ 1,0,2,
↦ 1,2,2

```

D.13.2.59 onesVector

Procedure from library `gfan.lib` (see [Section D.13.2 \[gfan.lib\]](#), page 2053).

Usage: `onesVector(n);` n int

Return: intvec, intvec of length n with all entries 1

Example:

```

LIB "gfan.lib";
intvec w = onesVector(3);
w;
↦ 1,1,1

```

D.13.3 gitfan.lib

Library: `gitfan.lib`

Purpose: Compute GIT-fans.

Authors: Janko Boehm, boehm at mathematik.uni-kl.de
 Simon Keicher, keicher at mail.mathematik.uni-tuebingen.de
 Yue Ren, ren at mathematik.uni-kl.de

Overview: This library allows you to calculate GIT-fans, torus orbits and GKZ-fans.

In provides features to make use of symmetries of the torus action under consideration.

The main procedure is `GITfan` which can be directly applied to an ideal and a grading matrix encoding the torus action, and returns a fan, the associated GIT-fan. We also provide various procedures implementing substeps of the algorithm to deal with large computations.

The library uses the package 'gfanlib' by Anders N. Jensen.

For notation, background, and algorithms see [BKR16].

Functions produce debug output if `printlevel` is positive.

Elements of the symmetric group S_n of type permutation can be created by the function `permutationFromIntvec`.

The images of $1, \dots, n$ can be obtained by `permutationToIntvec`. Composition of permutations can be done by the `*`-Operator, also powers can be computed in the usual way.

References:

[BKR16] J. Boehm, S. Keicher, Y. Ren: Computing GIT-Fans with Symmetry and the Mori Chamber Decomposition of M_{06}^{bar} , <https://arxiv.org/abs/1603.09241>

Types: permutation; Permutation in map representation.

Procedures:

D.13.3.1 isAface

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\]](#), page 2093).

Usage: `isAface(a,gam0)`; `a`: ideal, `gam0`:intvec

Purpose: Checks whether `gam0` is an a-face w.r.t. the ideal `a`.

Return: int

Example:

```
LIB "gitfan.lib";
ring R = 0,(T(1..4)),dp;
ideal I = T(1)*T(2)-T(4);
intvec w = 1,4;
intvec v = 1,2,4;
isAface(I,w); // should be 0
⇒ 0
isAface(I,v); // should be 1
⇒ 1
```

D.13.3.2 afaces

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\]](#), page 2093).

Usage: `afaces(a [,L])`; `a`: ideal, `L`: list of intvecs

Purpose: Returns a list of all a-faces (considered as intvecs of 0 and 1, where the *i*-th entry is 1 if the cone has the *i*-th unit basis vector as a generator), if `L` is specified only the faces of the simplex listed in `L` are considered (e.g. representatives with respect to a group action).

Return: a list of intvecs

Example:

```
LIB "gitfan.lib";
ring R = 0,T(1..3),dp;
ideal a = T(1)+T(2)+T(3);
list F = afaces(a);
print(F);
⇒ [1]:
⇒ 0
⇒ [2]:
⇒ 1,2
⇒ [3]:
⇒ 1,3
⇒ [4]:
⇒ 2,3
⇒ [5]:
⇒ 1,2,3
print(size(F));
⇒ 5
// 2nd ex //
```

```

ring R2 = 0,T(1..3),dp;
ideal a2 = T(2)^2*T(3)^2+T(1)*T(3);
list F2 = afaces(a2);
print(F2);
↳ [1]:
↳ 0
↳ [2]:
↳ 1
↳ [3]:
↳ 2
↳ [4]:
↳ 1,2
↳ [5]:
↳ 3
↳ [6]:
↳ 1,2,3
print(size(F2));
↳ 6
// 3rd ex //
ring R3 = 0,T(1..3),dp;
ideal a3 = 0;
list F3 = afaces(a3);
print(F3);
↳ [1]:
↳ 0
↳ [2]:
↳ 1
↳ [3]:
↳ 2
↳ [4]:
↳ 1,2
↳ [5]:
↳ 3
↳ [6]:
↳ 1,3
↳ [7]:
↳ 2,3
↳ [8]:
↳ 1,2,3
print(size(F3));
↳ 8
// 4th ex //
ring R4 = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
list F4 = afaces(J);
print(size(F4));
↳ 172

```

D.13.3.3 fullDimImages

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\], page 2093](#)).

Usage: `fullDimImages(afaces, Q);` `afaces`: list, `Q`: intmat

Purpose: Determines the a-faces (represented as intvecs) from the list `afaces` which have a full-dimensional projection with respect to `Q`.

Return: a list of intvecs

Example:

```
LIB "gitfan.lib";
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
intmat Q[5][10] =
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,
0, 1, 1, 0, 0, 0, -1, 1, 0, 0,
0, 1, 0, 1, 0, -1, 0, 0, 1, 0,
0, 0, 1, 1, -1, 0, 0, 0, 0, 1;
list AF= afaces(J,nrows(Q));
size(AF);
↳ 81
size(fullDimImages(AF,Q));
↳ 36
```

D.13.3.4 minimalAfaces

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\], page 2093](#)).

Usage: `minimalAfaces(listOfAfaces);` `listOfAfaces`: list

Purpose: Returns a list of all minimal a-faces. Note that `listOfAfaces` must only contain a-faces which project to full dimension.

Return: a list of intvecs

Example:

```
LIB "gitfan.lib";
setcores(4);
↳ 4
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
intmat Q[5][10] =
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,
```

```

0, 1, 1, 0, 0, 0, -1, 1, 0, 0,
0, 1, 0, 1, 0, -1, 0, 0, 1, 0,
0, 0, 1, 1, -1, 0, 0, 0, 0, 1;
list AF= afaces(J,nrows(Q));
size(AF);
↳ 81
AF=fullDimImages(AF,Q);
size(AF);
↳ 36
AF=minimalAfaces(AF);
size(AF);
↳ 25

```

D.13.3.5 orbitCones

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\], page 2093](#)).

Usage: `orbitCones(AF, Q[, d]);` AF: list of intvecs, Q: intmat, d: int

Purpose: Returns the list consisting of all cones $Q(\text{gam0})$ where gam0 in AF. If the optional argument d is given then the function returns only the orbit cones of dimension at least d

Return: a list of cones

Example:

```

LIB "gitfan.lib";
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
intmat Q[5][10] =
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,
0, 1, 1, 0, 0, 0, -1, 1, 0, 0,
0, 1, 0, 1, 0, -1, 0, 0, 1, 0,
0, 0, 1, 1, -1, 0, 0, 0, 0, 1;
list AF= afaces(J);
print(size(AF));
↳ 172
list OC = orbitCones(AF,Q);
size(OC);
↳ 172

```

D.13.3.6 GITcone

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\], page 2093](#)).

Usage: `GITcone(OCcones, w);` OCcones: list of orbit cones, w: bigintmat with one row

Purpose: Returns the intersection of all orbit cones containing w .

Return: cone,intvec with the GIT cone containing w , and the hash of this cone (the indices of the orbit cones contributing to the intersection)

Example:

```

LIB "gitfan.lib";
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
intmat Q[5][10] =
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,
0, 1, 1, 0, 0, 0, -1, 1, 0, 0,
0, 1, 0, 1, 0, -1, 0, 0, 1, 0,
0, 0, 1, 1, -1, 0, 0, 0, 0, 1;
list AF= afaces(J,nrows(Q));
AF=fullDimImages(AF,Q);
AF = minimalAfaces(AF);
list OC = orbitCones(AF,Q);
bigintmat w[1][nrows(Q)];
int j;
for(int i = 1; i <= nrows(Q); i++)
{
for(j=1;j<=nrows(Q);j++)
{
w[1,j]= w[1,j] + Q[1,i];
}
}
GITcone(OC,w);
⇒ AMBIENT_DIM
⇒ 5
⇒ FACETS
⇒ 0,0,0,0,1,
⇒ 0,1,0,0,0
⇒ LINEAR_SPAN
⇒ 1,0,0,0,-1,
⇒ 0,0,1,0,-1,
⇒ 0,0,0,1,-1
⇒ 3,5,6,8,10,11,12,14,16,17,18,19,20,21,22,23,24,25

```

D.13.3.7 GITfan

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\]](#), page 2093).

Usage: `GITfan(J,Q [, G]);` J:ideal, Q:intmat, G:list

Purpose: Computes the GIT fan associated to J and Q. Optionally a symmetry group action on the column space of Q can be specified.

Return: a fan, the GIT fan.

Note: The procedure uses parallel computation for the construction of the GIT-cones. The a-faces are not computed in parallel. This can be done by calling the `aface` procedure specifying a list of simplex faces. If used with the optional argument G, the orbit

decomposition of the simplex of columns of Q is computed. Refer to the Singular documentation on how to do this more efficiently using GAP.

Example:

```
LIB "gitfan.lib";
setcores(4);
↪ 4
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
intmat Q[5][10] =
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,
0, 1, 1, 0, 0, 0, -1, 1, 0, 0,
0, 1, 0, 1, 0, -1, 0, 0, 1, 0,
0, 0, 1, 1, -1, 0, 0, 0, 0, 1;
fan GIT = GITfan(J,Q);
intmat Q[5][10] =
↪ // ** redefining Q (intmat Q[5][10] => ./examples/GITfan.sing:17
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,
0, 1, 1, 0, 0, 0, -1, 1, 0, 0,
0, 1, 0, 1, 0, -1, 0, 0, 1, 0,
0, 0, 1, 1, -1, 0, 0, 0, 0, 1;
list simplexSymmetryGroup = G25Action();
fan GIT2 = GITfan(J,Q,simplexSymmetryGroup);
```

D.13.3.8 GITfanFromOrbitCones

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\]](#), page 2093).

Usage: `GITfanFromOrbitCones(OC, Q, Qgamma [, file1, file2]);` OC:list, Q:bigintmat, Qgamma:cone, file1:string, file2:string

Purpose: Returns the common refinement of the cones given in the list OC which is supposed to contain the orbit cones intersected with Qgamma. The optional argument can be used to specify one or two strings with file names, where the first file will contain the hashes of the GIT-cones and the second argument the actual cones in their H-representation. To obtain the whole GIT-fan Qgamma has to be take the cone generated by the columns of Q.

Return: a list containing the bigint hashes of the GIT cones.

Example:

```
LIB "gitfan.lib";
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
```

```

T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
intmat Q[5][10] =
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,
0, 1, 1, 0, 0, 0, -1, 1, 0, 0,
0, 1, 0, 1, 0, -1, 0, 0, 1, 0,
0, 0, 1, 1, -1, 0, 0, 0, 0, 1;
list AF= afaces(J,nrows(Q));
AF=fullDimImages(AF,Q);
AF = minimalAfaces(AF);
list OC = orbitCones(AF,Q);
cone Qgamma = coneViaPoints(transpose(Q));
list GIT = GITfanFromOrbitCones(OC,Q,Qgamma);
size(GIT);
↳ 76

```

D.13.3.9 GITfanParallel

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\]](#), page 2093).

Usage: `GITfanParallel(OC, Q, Qgamma [, file1]);` OC:list, Q:intmat, Qgamma:cone, file1:string

Purpose: Returns the common refinement of the cones given in the list OC which is supposed to contain the orbit cones intersected with Qgamma. The optional argument can be used to specify a name for a file which will contain the hashes of the GIT-cones. To obtain the whole GIT-fan Qgamma has to be take the cone generated by the columns of Q.

Return: a list containing the bigint hashes of the GIT cones.

Note: The procedure uses parallel computation for the construction of the GIT-cones.

Example:

```

LIB "gitfan.lib";
setcores(4);
↳ 4
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);

D.13.3.12 computeAfaceOrbits

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\]](#), page 2093).

Usage: `computeAfaceOrbits(AF,G)`; AF list of intvecs, G: list of permutations

Purpose: Computes the orbits of the afaces in the list AF under the group action in G, where G is a list of permutations. We assume that the elements of G form a group and the first entry corresponds to the neutral element.

Return: a list of lists of intvecs

Example:

```
LIB "gitfan.lib";
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
intmat Q[5][10] =
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,
0, 1, 1, 0, 0, 0, -1, 1, 0, 0,
0, 1, 0, 1, 0, -1, 0, 0, 1, 0,
0, 0, 1, 1, -1, 0, 0, 0, 0, 1;
list simplexSymmetryGroup = G25Action();
list simplexOrbitRepresentatives = intvec( 1, 2, 3, 4, 5 ),
intvec( 1, 2, 3, 5, 6 ),
intvec( 1, 2, 3, 5, 7 ),
intvec( 1, 2, 3, 5, 10 ),
intvec( 1, 2, 3, 7, 9 ),
intvec( 1, 2, 6, 9, 10 ),
intvec( 1, 2, 3, 4, 5, 6 ),
intvec( 1, 2, 3, 4, 5, 10 ),
intvec( 1, 2, 3, 5, 6, 8 ),
intvec( 1, 2, 3, 5, 6, 9 ),
intvec( 1, 2, 3, 5, 7, 10 ),
intvec( 1, 2, 3, 7, 9, 10 ),
intvec( 1, 2, 3, 4, 5, 6, 7 ),
intvec( 1, 2, 3, 4, 5, 6, 8 ),
intvec( 1, 2, 3, 4, 5, 6, 9 ),
intvec( 1, 2, 3, 5, 6, 9, 10 ),
intvec( 1, 2, 3, 4, 5, 6, 7, 8 ),
intvec( 1, 2, 3, 4, 5, 6, 9, 10 ),
intvec( 1, 2, 3, 4, 5, 6, 7, 8, 9 ),
intvec( 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 );
list afaceOrbitRepresentatives=afaces(J,simplexOrbitRepresentatives);

apply(afaceOrbits,size);
↪ 10 15 10 1
```

D.13.3.13 minimalAfaceOrbits

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\]](#), page 2093).

Usage: `minimalAfaceOrbits(afaceOrbits);` `afaceOrbits`: list

Purpose: Returns a list of all minimal a-face orbits.

Return: a list of intvecs

Example:

```
LIB "gitfan.lib";
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
intmat Q[5][10] =
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,
0, 1, 1, 0, 0, 0, -1, 1, 0, 0,
0, 1, 0, 1, 0, -1, 0, 0, 1, 0,
0, 0, 1, 1, -1, 0, 0, 0, 0, 1;
list simplexSymmetryGroup = G25Action();
list simplexOrbitRepresentatives = intvec( 1, 2, 3, 4, 5 ),
intvec( 1, 2, 3, 5, 6 ),
intvec( 1, 2, 3, 5, 7 ),
intvec( 1, 2, 3, 5, 10 ),
intvec( 1, 2, 3, 7, 9 ),
intvec( 1, 2, 6, 9, 10 ),
intvec( 1, 2, 3, 4, 5, 6 ),
intvec( 1, 2, 3, 4, 5, 10 ),
intvec( 1, 2, 3, 5, 6, 8 ),
intvec( 1, 2, 3, 5, 6, 9 ),
intvec( 1, 2, 3, 5, 7, 10 ),
intvec( 1, 2, 3, 7, 9, 10 ),
intvec( 1, 2, 3, 4, 5, 6, 7 ),
intvec( 1, 2, 3, 4, 5, 6, 8 ),
intvec( 1, 2, 3, 4, 5, 6, 9 ),
intvec( 1, 2, 3, 5, 6, 9, 10 ),
intvec( 1, 2, 3, 4, 5, 6, 7, 8 ),
intvec( 1, 2, 3, 4, 5, 6, 9, 10 ),
intvec( 1, 2, 3, 4, 5, 6, 7, 8, 9 ),
intvec( 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 );
list afaceOrbitRepresentatives=afaces(J,simplexOrbitRepresentatives);
list fullDimAfaceOrbitRepresentatives=fullDimImages(afaceOrbitRepresentatives,Q);
list afaceOrbits=computeAfaceOrbits(fullDimAfaceOrbitRepresentatives,simplexSymmetryGroup);
apply(afaceOrbits,size);
↳ 10 15 10 1
list minAfaceOrbits = minimalAfaceOrbits(afaceOrbits);
apply(minAfaceOrbits,size);
↳ 10 15
```

D.13.3.14 orbitConeOrbits

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\], page 2093](#)).

Usage: `orbitConeOrbits(F, Q);` F: list, Q: intmat

Purpose: Projects a list F of a-face orbits to the orbit cones with respect to Q. The function checks whether the projections are of full dimension and returns an error otherwise.

Return: a list of lists of cones

Example:

```
LIB "gitfan.lib";
// Note that simplexOrbitRepresentatives and simplexSymmetryGroup are subsets of the
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
intmat Q[5][10] =
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,
0, 1, 1, 0, 0, 0, -1, 1, 0, 0,
0, 1, 0, 1, 0, -1, 0, 0, 1, 0,
0, 0, 1, 1, -1, 0, 0, 0, 0, 1;
list simplexOrbitRepresentatives = intvec( 1, 2, 3, 4, 5 ),
intvec( 1, 2, 3, 5, 6 ),
intvec( 1, 2, 3, 5, 7 ),
intvec( 1, 2, 3, 5, 10 ),

D.13.3.16 intersectOrbitsWithMovingCone

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\]](#), page 2093).

Usage: `intersectOrbitsWithMovingCone(OCmin, mov);` OCmin: list of lists of cones, mov: cone

Purpose: Intersects all cones in the orbits in OCmin with mov discarding all orbits of cones which are not of full dimension. The resulting orbits are duplicate free.

Return: a list of lists of cones

Example:

```
LIB "gitfan.lib";
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
intmat Q[5][10] =

D.13.3.17 groupActionOnQImage

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\]](#), page 2093).

Usage: `groupActionOnQImage(G,Q)`; G: list of permutations, Q: intmat

Purpose: Given the group G of permutations acting on the simplex on `ncols(Q)` objects, computes the corresponding group action on the image of Q. We assume that the basering has characteristic 0.

Return: list of matrices

Example:

```

LIB "gitfan.lib";
ring R = 0,(x),dp;
intmat Q[5][10] =
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,
0, 1, 1, 0, 0, 0, -1, 1, 0, 0,
0, 1, 0, 1, 0, -1, 0, 0, 1, 0,
0, 0, 1, 1, -1, 0, 0, 0, 0, 1;
list generatorsG = permutationFromIntvec(intvec( 1, 3, 2, 4, 6, 5, 7, 8, 10, 9 )),
permutationFromIntvec(intvec( 5, 7, 1, 6, 9, 2, 8, 4, 10, 3 ));
groupActionOnQImage(generatorsG,Q);
⇒ [1]:
⇒ 1,0,0,0,0,
⇒ 0,1,0,0,0,
⇒ 0,0,1,0,0,
⇒ 0,0,0,0,1,
⇒ 0,0,0,1,0
⇒ [2]:
⇒ -1,1,1,0,1,

```

D.13.3.18 groupActionOnHashes

Usage: groupActionOnHashes(Asigma,OCmov); Asigma: list, Ocmov: list of list of cones

Return: list of permutations

```
LIB "gitfan.lib";
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
intmat Q[5][10] =
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,
0, 1, 1, 0, 0, 0, -1, 1, 0, 0,
0, 1, 0, 1, 0, -1, 0, 0, 1, 0,
0, 0, 1, 1, -1, 0, 0, 0, 0, 1;
list AF= afaces(J);
list OC = orbitCones(AF,Q);
list generatorsG = permutationFromIntvec(intvec( 1, 3, 2, 4, 6, 5, 7, 8, 10, 9 )),
permutationFromIntvec(intvec( 5, 7, 1, 6, 9, 2, 8, 4, 10, 3 ));
list Asigmagens = groupActionOnQImage(generatorsG,Q);
groupActionOnHashes(Asigmagens,list(OC));

D.13.3.19 storeActionOnOrbitConeIndices

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\], page 2093](#)).

Usage: `storeActionOnOrbitConeIndices(generatorsGperm,st);` generatorsGperm: list, fn: string

Purpose: Write the action on the set of orbit cones to the file fn in Singular readable format.

Return: nothing

D.13.3.20 permutationFromIntvec

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\], page 2093](#)).

Usage: `permutationFromIntvec(sigmaImage);` sigmaImage: intvec

Purpose: Create a permutation from an intvec of images.

Return: permutation

D.13.3.21 permutationToIntvec

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\], page 2093](#)).

Usage: `permutationToIntvec(sigma);` sigma: permutation

Purpose: Convert a permutation to an intvec of images.

Return: intvec

Example:

```

LIB "gitfan.lib";
permutation sigma = permutationFromIntvec(intvec( 1, 2, 4, 3, 5, 7, 6, 9, 8, 10 ));
sigma;
⇒ | 1 2 3 4 5 6 7 8 9 10|
⇒ | 1 2 4 3 5 7 6 9 8 10|
⇒
permutationToIntvec(sigma);
⇒ 1,2,4,3,5,7,6,9,8,10

```

D.13.3.22 evaluateProduct

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\]](#), page 2093).

Usage: `evaluateProduct(generatorsGperm,st);` generatorsGperm: list, st: string

Purpose: Evaluates a formal product of variables x_i in `st`, where x_i corresponds to the permutation `generatorsGperm[i]`.

Return: permutation

Example:

```
LIB "gitfan.lib";
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
intmat Q[5][10] =
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,

```

D.13.3.23 GITfanSymmetric

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\]](#), page 2093).

Usage: `GITfanSymmetric(OC, Q, Qgamma, actiononorbitcones [, file1, file2]);` OC:list, Q:bigintmat, Qgamma:cone, actiononorbitcones: list of intvec, file1:string, file2:string

Purpose: Returns the common refinement of the cones given in the list `OC` which is supposed to contain the orbit cones intersected with `Qgamma`. The list `actiononorbitcones` is supposed to contain the symmetry group acting as permutations of on the list of orbit cones in `OC`. The optional argument can be used to specify one or two strings with file names, where the first file will contain the hashes of the GIT-cones and the second argument the actual cones in their H-representation. To obtain the whole GIT-fan `Qgamma` has to be take the cone generated by the columns of `Q`.

Return: a list containing the bigint hashes of the GIT cones.

Example:

```

LIB "gitfan.lib";
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);

D.13.3.24 GITfanParallelSymmetric

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\]](#), page 2093).

Usage: `GITfanParallelSymmetric(OC, Q, Qgamma, actiononorbitcones [, file1]);` OC:list, Q:bigintmat, Qgamma:cone, actiononorbitcones: list of intvec, file1:string

Purpose: Returns the common refinement of the cones given in the list OC which is supposed to contain the orbit cones intersected with Qgamma. The list actiononorbitcones is supposed to contain the symmetry group acting as permutations of on the list of orbit cones in OC. The optional argument can be used to specify a name for a file which will contain the hashes of the GIT-cones. To obtain the whole GIT-fan Qgamma has to be take the cone generated by the columns of Q.

Return: a list containing the bigint hashes of the GIT cones.

Note: The procedure uses parallel computation for the construction of the GIT-cones.

Example:

```

LIB "gitfan.lib";
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);

```

```

ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),

D.13.3.25 bigintToBinary

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\], page 2093](#)).

Usage: `bigintToBinary(n, r)`: n bigint, r int.

Assume: n is smaller than 2^r .

Return: an intvec, with entries the positions of 1 in the binary representation of n with r bits.

Example:

```

LIB "gitfan.lib";
bigintToBinary(bigint(2)^90-1, 90);
↳ 1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,27,2\
8,29,30,31,32,33,34,35,36,37,38,39,40,41,42,43,44,45,46,47,48,49,50,51,52\
,53,54,55,56,57,58,59,60,61,62,63,64,65,66,67,68,69,70,71,72,73,74,75,76,\
77,78,79,80,81,82,83,84,85,86,87,88,89,90

```

D.13.3.26 binaryToBigint

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\], page 2093](#)).

D.13.3.27 applyPermutationToIntvec

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\], page 2093](#)).

Usage: `applyPermutationToIntvec(v,g)`; v : intvec, g : permutation

Purpose: Apply g to the set of entries of v . The result is a sorted intvec. We assume that the entries of v are valid arguments of g . We do not require that the input is sorted.

Return: intvec.

Example:

```

LIB "gitfan.lib";
permutation g = permutationFromIntvec(intvec(10, 9, 7, 4, 8, 6, 3, 5, 2, 1));
applyPermutationToIntvec(intvec(1, 3, 4, 6, 8),g);
↳ 4,5,6,7,10

```

D.13.3.28 hashToCone

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\], page 2093](#)).

Usage: `hashToCone(v, OC)`: `v` bigint, `OC` list of cones.

Assume: the elements of `OC` are the orbit cones used in the hash representation of the GIT cones.

Return: a cone, the intersection of the cones in `OC` according to the binary representation of the hash `v`.

Example:

```
LIB "gitfan.lib";
setcores(4);
↪ 4
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
intmat Q[5][10] =
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,
0, 1, 1, 0, 0, 0, -1, 1, 0, 0,
0, 1, 0, 1, 0, -1, 0, 0, 1, 0,
0, 0, 1, 1, -1, 0, 0, 0, 0, 1;
list AF= afaces(J,nrows(Q));
AF=fullDimImages(AF,Q);
AF = minimalAfaces(AF);
list OC = orbitCones(AF,Q);
bigint v = 21300544;
hashToCone(v, OC);

```

D.13.3.29 hashesToFan

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\], page 2093](#)).

Usage: `hashesToFan(hashes, OC)`: `hashes` list of bigint, `OC` list of cones.

Assume: the elements of `OC` are the orbit cones used in the hash representation of the GIT cones.

Return: a fan, with maximal cones the intersections of the cones in OC according to the binary representation of the hashes.

Example:

```
LIB "gitfan.lib";
setcores(4);
↪ 4
ring R = 0,T(1..10),wp(1,1,1,1,1,1,1,1,1,1);
ideal J =
T(5)*T(10)-T(6)*T(9)+T(7)*T(8),
T(1)*T(9)-T(2)*T(7)+T(4)*T(5),
T(1)*T(8)-T(2)*T(6)+T(3)*T(5),
T(1)*T(10)-T(3)*T(7)+T(4)*T(6),
T(2)*T(10)-T(3)*T(9)+T(4)*T(8);
intmat Q[5][10] =
1, 1, 1, 1, 0, 0, 0, 0, 0, 0,
1, 0, 0, 0, 1, 1, 1, 0, 0, 0,
0, 1, 1, 0, 0, 0, 0, -1, 1, 0,
0, 1, 0, 1, 0, -1, 0, 0, 1, 0,
0, 0, 1, 1, -1, 0, 0, 0, 0, 1;
list AF= afaces(J,nrows(Q));
AF=fullDimImages(AF,Q);
AF = minimalAfaces(AF);
list OC = orbitCones(AF,Q);
cone Qgamma = coneViaPoints(transpose(Q));
list GIT = GITfanParallel(OC,Q,Qgamma);
fan Sigma = hashesToFan(GIT,OC);
```

D.13.3.30 gitCone

Procedure from library `gitfan.lib` (see [Section D.13.3 \[gitfan.lib\]](#), page 2093).

Usage: `gitCone(a, Q, w)`; a: ideal, Q:bigintmat, w:bigintmat

Purpose: Returns the GIT-cone $\lambda(w)$, i.e. the intersection of all orbit cones containing the vector w.

Note: call this only if you are interested in a single GIT-cone.

Return: a cone.

Example:

```
LIB "gitfan.lib";
intmat Q[3][4] =
1,0,1,0,
0,1,0,1,
0,0,1,1;
ring R = 0,T(1..4),dp;
ideal a = 0;
bigintmat w[1][3] = 3,3,1;
cone lambda = gitCone(a, Q, w);
rays(lambda);
↪ 1,0,0,
↪ 0,1,0,
↪ 1,1,1
```

```

bigintmat w2[1][3] = 1,1,1;
cone lambda2 = gitCone(a, Q, w2);
rays(lambda2);
↳ 1,1,1

```

D.13.4 polymake_lib

Library: polymake.lib

Purpose: Computations with polytopes and fans, interface to TOPCOM

Author: Thomas Markwig, email: keilen@mathematik.uni-kl.de
Yue Ren, email: ren@mathematik.uni-kl.de

Warning: Most procedures will not work unless polymake or topcom is installed and if so, they will only work with the operating system LINUX! For more detailed information see IMPORTANT NOTE respectively consult the help string of the procedures.

The conventions used in this library for polytopes and fans, e.g. the length and labeling of their vertices resp. rays, differs from the conventions used in polymake and thus from the conventions used in the polymake extension polymake.so of Singular. We recommend to use the newer polymake.so whenever possible.

Important note:

Even though this is a Singular library for computing polytopes and fans such as the Newton polytope or the Groebner fan of a polynomial, most of the hard computations are NOT done by Singular but by the program

- TOPCOM by Joerg Rambau, Universitaet Bayreuth (see http://www.uni-bayreuth.de/de/team/rambau_joerg/TOPCOM/);

this library should rather be seen as an interface which allows to use a (very limited) number of options which topcom offers to compute with polytopes and fans and to make the results available in Singular for further computations; moreover, the user familiar with Singular does not have to learn the syntax of topcom, if the options offered here are sufficient for his purposes.

Note, though, that the procedures concerned with planar polygons are independent of topcom.

Procedures using topcom: Procedures concerned with planar polygons:

D.13.4.1 triangulations

Procedure from library `polymake.lib` (see [Section D.13.4 \[polymake_lib\]](#), page 2132).

Usage: `triangulations(polygon[,#]);` list polygon, list #

Assume: polygon is a list of integer vectors of the same size representing the affine coordinates of the lattice points

Purpose: the procedure considers the marked polytope given as the convex hull of the lattice points and with these lattice points as markings; it then computes all possible triangulations of this marked polytope

Return: list, each entry corresponds to one triangulation and the *i*th entry is itself a list of integer vectors of size three, where each integer vector defines one triangle in the triangulation by telling which points of the input are the vertices of the triangle

- Note:**
- the procedure calls for its computations the program `points2triangs` from the program `topcom` by Joerg Rambau, Universitaet Bayreuth; it therefore is necessary that this program is installed in order to use this procedure; see <http://www.rambau.wm.uni-bayreuth.de/TOPCOM/>;
 - if you only want to have the regular triangulations the procedure should be called with the string `'regular'` as optional argument
 - the procedure creates the files `/tmp/triangulationsinput` and `/tmp/triangulationsoutput`; the former is used as input for `points2triangs` and the latter is its output containing the triangulations of corresponding to points in the format of `points2triangs`; if you wish to use this for further computations with `topcom`, you have to call the procedure with the string `'keepfiles'` as optional argument
 - note that an integer `i` in an integer vector representing a triangle refers to the `i`th lattice point, i.e. `polygon[i]`; this convention is different from TOPCOM's convention, where `i` would refer to the `i-1`st lattice point

Example:

```
LIB "polymake.lib";
// the lattice points of the unit square in the plane
list polygon=intvec(0,0),intvec(0,1),intvec(1,0),intvec(1,1);
// the triangulations of this lattice point configuration are computed
list triang=triangulations(polygon);
⇒ Evaluating Commandline Options ...
⇒ ... done.
⇒ 0
⇒ 0
triang;
⇒ [1]:
⇒   [1]:
⇒     1,2,3
⇒   [2]:
⇒     2,3,4
⇒ [2]:
⇒   [1]:
⇒     1,3,4
⇒   [2]:
⇒     1,2,4
```

D.13.4.2 secondaryPolytope

Procedure from library `polymake.lib` (see [Section D.13.4 \[polymake.lib\]](#), page 2132).

Usage: `secondaryPolytope(polygon[,#]);` list polygon, list #

Assume:

- polygon is a list of integer vectors of the same size representing the affine coordinates of lattice points
- if the triangulations of the corresponding polygon have already been computed with the procedure `triangulations` then these can be given as a second (optional) argument in order to avoid doing this computation again

Purpose: the procedure considers the marked polytope given as the convex hull of the lattice points and with these lattice points as markings; it then computes the lattice points of the secondary polytope given by this marked polytope which correspond to the triangulations computed by the procedure `triangulations`

- Return:** list, say L , such that:
 $L[1]$ = intmat, each row gives the affine coordinates of a lattice point in the secondary polytope given by the marked polytope corresponding to polygon
 $L[2]$ = the list of corresponding triangulations
- Note:** if the triangulations are not handed over as optional argument the procedure calls for its computation of these triangulations the program `points2triangs` from the program `topcom` by Joerg Rambau, Universitaet Bayreuth; it therefore is necessary that this program is installed in order to use this procedure; see <http://www.rambau.wm.uni-bayreuth.de/TOPCOM/>;

Example:

```
LIB "polymake.lib";
// the lattice points of the unit square in the plane
list polygon=intvec(0,0),intvec(0,1),intvec(1,0),intvec(1,1);
// the secondary polytope of this lattice point configuration is computed
list secpoly=secondaryPolytope(polygon);
⇒ Evaluating Commandline Options ...
⇒ ... done.
⇒ 0
⇒ 0
// the points in the secondary polytope
print(secpoly[1]);
⇒      1      2      2      1

⇒      [2]:
⇒      2,3,4
⇒ [2]:
⇒      [1]:
⇒      1,3,4
⇒      [2]:
⇒      1,2,4
```

D.13.4.3 cycleLength

Procedure from library `polymake.lib` (see [Section D.13.4 \[polymake.lib\]](#), page 2132).

- Usage:** `cycleLength(boundary,interior)`; list boundary, intvec interior
- Assume:** boundary is a list of integer vectors describing a cycle in some convex lattice polygon around the lattice point interior ordered clock wise
- Return:** string, the cycle length of the corresponding cycle in the dual tropical curve

Example:

```
LIB "polymake.lib";
// the integer vectors in boundary are lattice points on the boundary
// of a convex lattice polygon in the plane
list boundary=intvec(0,0),intvec(0,1),intvec(0,2),intvec(2,2),
```

```

intvec(2,1),intvec(2,0);
// interior is a lattice point in the interior of this lattice polygon
intvec interior=1,1;
// compute the general cycle length of a cycle of the corresponding cycle
// in the dual tropical curve, note that (0,1) and (2,1) do not contribute
cycleLength(boundary,interior);
↪ -4*u11+u00+u02+u22+u20

```

D.13.4.4 splitPolygon

Procedure from library `polymake.lib` (see [Section D.13.4 \[polymake.lib\]](#), page 2132).

Usage: `splitPolygon (markings);` markings list

Assume: markings is a list of integer vectors representing lattice points in the plane which we consider as the marked points of the convex lattice polytope spanned by them

Purpose: split the marked points in the vertices, the points on the facets which are not vertices, and the interior points

Return: list, L consisting of three lists
`L[1]` : represents the vertices the polygon ordered clockwise
`L[1][i][1]` = intvec, the coordinates of the *i*th vertex
`L[1][i][2]` = int, the position of `L[1][i][1]` in markings
`L[2][i]` : represents the lattice points on the facet of the polygon with endpoints `L[1][i]` and `L[1][i+1]`
(i considered modulo size(L[1]))
`L[2][i][j][1]` = intvec, the coordinates of the *j*th lattice point on that facet
`L[2][i][j][2]` = int, the position of `L[2][i][j][1]` in markings
`L[3]` : represents the interior lattice points of the polygon
`L[3][i][1]` = intvec, coordinates of *i*th interior point
`L[3][i][2]` = int, the position of `L[3][i][1]` in markings

Example:

```

LIB "polymake.lib";
// the lattice polygon spanned by the points (0,0), (3,0) and (0,3)
// with all integer points as markings
list polygon=intvec(1,1),intvec(3,0),intvec(2,0),intvec(1,0),
intvec(0,0),intvec(2,1),intvec(0,1),intvec(1,2),
intvec(0,2),intvec(0,3);
// split the polygon in its vertices, its facets and its interior points
list sp=splitPolygon(polygon);
// the vertices

D.13.4.5 eta

Procedure from library `polymake.lib` (see [Section D.13.4 \[polymake.lib\]](#), page 2132).

Usage: `eta(triang,polygon);` triang, polygon list

- Assume:** polygon has the format of the output of `splitPolygon`, i.e. it is a list with three entries describing a convex lattice polygon in the following way:
 polygon[1] : is a list of lists; for each i the entry `polygon[1][i][1]` is a lattice point which is a vertex of the lattice
 polygon, and `polygon[1][i][2]` is an integer assigned to this lattice point as identifying index
 polygon[2] : is a list of lists; for each vertex of the polygon, i.e. for each entry in `polygon[1]`, it contains a list `polygon[2][i]`, which contains the lattice points on the facet with endpoints `polygon[1][i]` and `polygon[1][i+1]` - i considered mod `size(polygon[1])`; each such lattice point contributes an entry `polygon[2][i][j][1]` which is an integer vector giving the coordinate of the lattice point and an entry `polygon[2][i][j][2]` which is the identifying index
 polygon[3] : is a list of lists, where each entry corresponds to a lattice point in the interior of the polygon, with `polygon[3][j][1]` being the coordinates of the point and `polygon[3][j][2]` being the identifying index;
 triang is a list of integer vectors all of size three describing a triangulation of the polygon described by `polygon`; if an entry of `triang` is the vector (i,j,k) then the triangle is built by the vertices with indices i, j and k
- Return:** `intvec`, the integer vector `eta` describing that vertex of the Newton polytope discriminant of the polygon whose dual cone in the Groebner fan contains the cone of the secondary fan of the polygon corresponding to the given triangulation
- Note:** for a better description of `eta` see Gelfand, Kapranov, Zelevinski: Discriminants, Resultants and multidimensional Determinants. Chapter 10.

Example:

```
LIB "polymake.lib";
// the lattice polygon spanned by the points (0,0), (3,0) and (0,3)
// with all integer points as markings
list polygon=intvec(1,1),intvec(3,0),intvec(2,0),intvec(1,0),
intvec(0,0),intvec(2,1),intvec(0,1),intvec(1,2),
intvec(0,2),intvec(0,3);
// split the polygon in its vertices, its facets and its interior points
list sp=splitPolygon(polygon);
// define a triangulation by connecting the only interior point
// with the vertices
list triang=intvec(1,2,5),intvec(1,5,10),intvec(1,5,10);
// compute the eta-vector of this triangulation
eta(triang,sp);
⇒ 9,1,0,0,1,0,0,0,0,1
```

D.13.4.6 findOrientedBoundary

Procedure from library `polymake.lib` (see [Section D.13.4 \[polymake.lib\]](#), page 2132).

- Usage:** `findOrientedBoundary(polygon)`; `polygon` list
- Assume:** `polygon` is a list of integer vectors defining integer lattice points in the plane
- Return:** list `l` with the following interpretation
`l[1]` = list of integer vectors such that the polygonal path defined by these is the

boundary of the convex hull of the lattice points in polygon
 $l[2]$ = list, the redundant points in $l[1]$ have been removed

Example:

```
LIB "polymake.lib";
// the following lattice points in the plane define a polygon
list polygon=intvec(0,0),intvec(3,1),intvec(1,0),intvec(2,0),
intvec(1,1),intvec(3,2),intvec(1,2),intvec(2,3),
intvec(2,4);
// we compute its boundary
list boundarypolygon=findOrientedBoundary(polygon);
// the points on the boundary ordered clockwise are boundarypolygon[1]
boundarypolygon[1];
⇒ [1]:
⇒ 0,0
⇒ [2]:
⇒ 1,2
⇒ [3]:
⇒ 2,4
⇒ [4]:
⇒ 3,2
⇒ [5]:
⇒ 3,1
⇒ [6]:
⇒ 2,0
⇒ [7]:
⇒ 1,0
// the vertices of the boundary are boundarypolygon[2]
boundarypolygon[2];
⇒ [1]:
⇒ 0,0
⇒ [2]:
⇒ 2,4
⇒ [3]:
⇒ 3,2
⇒ [4]:
⇒ 3,1
⇒ [5]:
⇒ 2,0
```

D.13.4.7 cyclePoints

Procedure from library `polymake.lib` (see [Section D.13.4 \[polymake.lib\]](#), page 2132).

Usage: `cyclePoints(triang,points,pt)` triang,points list, pt int

Assume:

- points is a list of integer vectors describing the lattice points of a marked polygon;
- triang is a list of integer vectors describing a triangulation of the marked polygon in the sense that an integer vector of the form (i,j,k) describes the triangle formed by `polygon[i]`, `polygon[j]` and `polygon[k]`;
- pt is an integer between 1 and `size(points)`, singling out a lattice point among the marked points

Purpose: consider the convex lattice polygon, say P , spanned by all lattice points in points which in the triangulation triang are connected to the point `points[pt]`; the procedure

computes all marked points in points which lie on the boundary of that polygon, ordered clockwise

Return: list, of integer vectors which are the coordinates of the lattice points on the boundary of the above mentioned polygon P, if this polygon is not the empty set (that would be the case if points[pt] is not a vertex of any triangle in the triangulation); otherwise return the empty list

Example:

```
LIB "polymake.lib";
// the lattice polygon spanned by the points (0,0), (3,0) and (0,3)
// with all integer points as markings
list points=intvec(1,1),intvec(3,0),intvec(2,0),intvec(1,0),
intvec(0,0),intvec(2,1),intvec(0,1),intvec(1,2),
intvec(0,2),intvec(0,3);
// define a triangulation
list triang=intvec(1,2,5),intvec(1,5,7),intvec(1,7,9),intvec(8,9,10),
intvec(1,8,9),intvec(1,2,8);
// compute the points connected to (1,1) in triang
cyclePoints(triang,points,1);
⇒ [1]:
⇒ 3,0
⇒ [2]:
⇒ 0,0
⇒ [3]:
⇒ 0,1
⇒ [4]:
⇒ 0,2
⇒ [5]:
⇒ 1,2
```

D.13.4.8 latticeArea

Procedure from library `polymake.lib` (see [Section D.13.4 \[polymake.lib\]](#), page 2132).

Usage: `latticeArea(polygon)`; polygon list

Assume: polygon is a list of integer vectors in the plane

Return: int, the lattice area of the convex hull of the lattice points in polygon, i.e. twice the Euclidean area

Example:

```
LIB "polymake.lib";
// define a polygon with lattice area 5
list polygon=intvec(1,2),intvec(1,0),intvec(2,0),intvec(1,1),
intvec(2,1),intvec(0,0);
latticeArea(polygon);
⇒ 5
```

D.13.4.9 picksFormula

Procedure from library `polymake.lib` (see [Section D.13.4 \[polymake.lib\]](#), page 2132).

Usage: `picksFormula(polygon)`; polygon list

Assume: polygon is a list of integer vectors in the plane and consider their convex hull C

Return: list, L of three integers
 L[1] : the lattice area of C, i.e. twice the Euclidean area
 L[2] : the number of lattice points on the boundary of C
 L[3] : the number of interior lattice points of C

Note: the integers in L are related by Pick's formula, namely: $L[1] = L[2] + 2 \cdot L[3] - 2$

Example:

```
LIB "polymake.lib";
// define a polygon with lattice area 5
list polygon=intvec(1,2),intvec(1,0),intvec(2,0),intvec(1,1),
intvec(2,1),intvec(0,0);
list pick=picksFormula(polygon);
// the lattice area of the polygon is:
pick[1];
⇒ 5
// the number of lattice points on the boundary is:
pick[2];
⇒ 5
// the number of interior lattice points is:
pick[3];
⇒ 1
// the number's are related by Pick's formula:
pick[1]-pick[2]-2*pick[3]+2;
⇒ 0
```

D.13.4.10 ellipticNF

Procedure from library `polymake.lib` (see [Section D.13.4 \[polymake.lib\]](#), page 2132).

Usage: `ellipticNF(polygon);` polygon list

Assume: polygon is a list of integer vectors in the plane such that their convex hull C has precisely one interior lattice point; i.e. C is the Newton polygon of an elliptic curve

Purpose: compute the normal form of the polygon with respect to the unimodular affine transformations $T = A \cdot x + v$; there are sixteen different normal forms (see e.g. Bjorn Poonen, Fernando Rodriguez-Villegas: Lattice Polygons and the number 12. Amer. Math. Monthly 107 (2000), no. 3, 238–250.)

Return: list, L such that
 L[1] : list whose entries are the vertices of the normal form of the polygon
 L[2] : the matrix A of the unimodular transformation
 L[3] : the translation vector v of the unimodular transformation
 L[4] : list such that the ith entry is the image of `polygon[i]` under the unimodular transformation T

Example:

```
LIB "polymake.lib";
ring r=0,(x,y),dp;
// the Newton polygon of the following polynomial
// has precisely one interior point
poly f=x22y11+x19y10+x17y9+x16y9+x12y7+x9y6+x7y5+x2y3;
list polygon=list(intvec(22,11),intvec(19,10),intvec(17,9),
```

```

intvec(16,9), intvec(12,7),intvec(9,6),
intvec(7,5),intvec(2,3));
// its lattice points are
polygon;
⇒ [1]:
⇒ 22,11
⇒ [2]:
⇒ 19,10
⇒ [3]:
⇒ 17,9
⇒ [4]:
⇒ 16,9
⇒ [5]:
⇒ 12,7
⇒ [6]:
⇒ 9,6
⇒ [7]:
⇒ 7,5
⇒ [8]:
⇒ 2,3
// find its normal form
list nf=ellipticNF(polygon);
// the vertices of the normal form are
nf[1];
⇒ [1]:
⇒ 4,0
⇒ [2]:
⇒ 0,0
⇒ [3]:
⇒ 0,2
// it has been transformed by the unimodular affine transformation A*x+v
// with matrix A
nf[2];
⇒ 3,-7,
⇒ -2,5
// and translation vector v
nf[3];
⇒ 15,-11
// the 3rd lattice point ...
polygon[3];
⇒ 17,9
// ... has been transformed to
nf[4][3];
⇒ 3,0

```

D.13.5 realizationMatroids_lib

Library: realizationMatroids.lib

Purpose: Deciding Relative Realizability for Tropical Fan Curves in 2-Dimensional Matroidal Fans

Authors: Anna Lena Winstel, winstel@mathematik.uni-kl.de

Overview: In tropical geometry, one question to ask is the following: given a one-dimensional balanced polyhedral fan C which is set theoretically contained in the tropicalization $\text{trop}(Y)$ of an algebraic variety Y , does there exist a curve X in Y such that $\text{trop}(X) = C$? This equality of C and $\text{trop}(X)$ denotes an equality of both, the fans $\text{trop}(X)$ and C and their weights on the maximal cones. The relative realization space of C with respect to Y is the space of all algebraic curves in Y which tropicalize to C .

This library provides procedures deciding relative realizability for tropical fan curves, i.e. one-dimensional weighted balanced polyhedral fans, contained in two-dimensional matroidal fans $\text{trop}(Y)$ where Y is a projective plane.

Notation: If Y is a projective plane in $(n-1)$ -dimensional projective space, we consider $\text{trop}(Y)$ in $\mathbb{R}^n/\langle 1 \rangle$. Moreover, for the relative realization space of C with respect to Y we only consider algebraic curves of degree $\deg(C)$ in Y which tropicalize to C .

Procedures:

D.13.5.1 realizationDim

Procedure from library `realizationMatroids.lib` (see [Section D.13.5 \[realizationMatroids.lib\]](#), [page 2141](#)).

Usage: `realizationDim(I,C)`; where I is a homogeneous linear ideal defining the projective plane $Y = V(I)$ and C is a list of intvectors such that each intvector represents a one-dimensional cone in the tropical fan curve whose relative realizability should be checked. This representation is done in the following way: the one-dimensional cone K is represented by a vector w whose equivalence class $[w]$ in $\mathbb{R}^n/\langle 1 \rangle$ can be written as $[w] = m*[v]$ where $[v]$ is the primitive generator of K and m is the weight of K .

Returns: the dimension of the relative realization space of the tropical curve C with respect to Y , and -1 if the relative realization space is empty.

Example:

```
LIB "realizationMatroids.lib";
ring r = 0,(x(1..4)),dp;
ideal I = x(1)+x(2)+x(3)+x(4);
list C = list(intvec(2,2,0,0),intvec(0,0,2,1),intvec(0,0,0,1));
//C represents the tropical fan curve which consists of the cones
//cone([(1,1,0,0)]) (with weight 2), cone([(0,0,2,1)]) (with weight 1)
//and cone([(0,0,0,1)]) (with weight 1)
realizationDim(I,C);
↦ -1
```

D.13.5.2 irrRealizationDim

Procedure from library `realizationMatroids.lib` (see [Section D.13.5 \[realizationMatroids.lib\]](#), [page 2141](#)).

Usage: `irrRealizationDim(I,C)`; where I is a homogeneous linear ideal defining the projective plane $Y = V(I)$ and C is a list of intvectors such that each intvector represents a one-dimensional cone in the tropical fan curve whose irreducible relative realizability should be checked. This representation is done in the following way: a one-dimensional cone K is represented by a vector w whose equivalence class $[w]$ in $\mathbb{R}^n/\langle 1 \rangle$ can be written as $[w] = m*[v]$ where $[v]$ is the primitive generator of K and m is the weight of K .

Returns: the dimension of the irreducible relative realization space of C with respect to Y , and -1 if the irreducible realization space is empty.

Example:

```
LIB "realizationMatroids.lib";
ring r = 0,(x(1..4)),dp;
ideal I = x(1)+x(2)+x(3)+x(4);
list C = list(intvec(2,2,0,0),intvec(0,0,2,2));
//C represents the tropical fan curve which consists of the cones
//cone([(1,1,0,0)]) and cone([(1,1,0,0)]), both with weight 2
realizationDim(I,C);
↦ 0
irrRealizationDim(I,C);
↦ -1
```

D.13.5.3 realizationDimPoly

Procedure from library `realizationMatroids.lib` (see [Section D.13.5 \[realizationMatroids.lib\]](#), page 2141).

Usage: `realizationDimPoly(I,C)`; where I is a homogeneous linear ideal defining the projective plane $Y = V(I)$ and C is a list of intvectors such that each intvector represents a one-dimensional cone in the tropical fan curve whose relative realizability should be checked. This representation is done in the following way: the one-dimensional cone K is represented by a vector w whose equivalence class $[w]$ in $R^n / \langle 1 \rangle$ can be written as $[w] = m[v]$ where $[v]$ is the primitive generator of K and m is the weight of K .

Returns: If the relative realization space of the tropical fan curve C is non-empty, this routine returns the tuple (r,f) , where r is the dimension of the relative realization space and f is an example of a homogeneous polynomial of degree $\deg(C)$ cutting out a curve X in Y which tropicalizes to C . In case the relative realization space is empty, the output is set to -1.

Example:

```
LIB "realizationMatroids.lib";
ring r = 0,(x(1..4)),dp;
ideal I = x(1)+x(2)+x(3)+x(4);
list C = list(intvec(2,2,0,0),intvec(0,0,2,2));
//C represents the tropical fan curve which consists of the cones
//cone([(1,1,0,0)]) and cone([(1,1,0,0)]), both with weight 2
realizationDimPoly(I,C);
↦ 0 x(1)^2+2*x(1)*x(2)+x(2)^2
C = list(intvec(0,0,0,4),intvec(0,1,3,0),intvec(1,0,1,0),intvec(0,2,0,0),intvec(3,1,0,0));
//C represents the tropical fan curve which consists of the cones
//cone([(0,0,0,1)]) with weight 4,
//cone([(0,1,3,0)]), cone([(1,0,1,0)]) both with weight 1,
//cone([(0,1,0,0)]) with weight 2, and
//cone([(3,1,0,0)]) with weight 1
realizationDimPoly(I,C);
↦ 7 x(1)*x(2)^3+x(1)^3*x(3)+x(2)^3*x(3)+x(1)*x(3)^3
```

D.13.6 tropical_lib

Library: `tropical.lib`

Purpose: Computations in Tropical Geometry

Authors: Anders Jensen Needergard, email: jensen@math.tu-berlin.de
 Hannah Markwig, email: hannah@uni-math.gwdg.de
 Thomas Markwig, email: keilen@mathematik.uni-kl.de
 Yue Ren, email: ren@mathematik.uni-kl.de

Warning: - tropicalLifting will only work with LINUX and if in addition gfan is installed.
 - drawTropicalCurve and drawTropicalNewtonSubdivision will only display the tropical curve with LINUX and if in addition latex and xdg-open are installed.
 - For tropicalLifting in the definition of the basering the parameter t from the Puiseux series field $C\{\{t\}\}$ must be defined as a variable, while for all other procedures it must be defined as a parameter.

Theory: Fix some base field K and a bunch of lattice points v_0, \dots, v_m in the integer lattice Z^n , then this defines a toric variety as the closure of $(K^*)^n$ in the projective space P^m , where the torus is embedded via the map sending a point x in $(K^*)^n$ to the point $(x^{v_0}, \dots, x^{v_m})$.

The generic hyperplane sections are just the images of the hypersurfaces in $(K^*)^n$ defined by the polynomials $f = a_0 x^{v_0} + \dots + a_m x^{v_m} = 0$. Some properties of these hypersurfaces can be studied via tropicalisation.

For this we suppose that $K = C\{\{t\}\}$ is the field of Puiseux series over the field of complex numbers (or any other field with a valuation into the real numbers). One associates to the hypersurface given by $f = a_0 x^{v_0} + \dots + a_m x^{v_m}$ the tropical hypersurface defined by the tropicalisation $\text{trop}(f) = \min\{\text{val}(a_0) + \langle v_0, x \rangle, \dots, \text{val}(a_m) + \langle v_m, x \rangle\}$.

Here, $\langle v, x \rangle$ denotes the standard scalar product of the integer vector v in Z^n with the vector $x = (x_1, \dots, x_n)$ of variables, so that $\text{trop}(f)$ is a piecewise linear function on R^n . The corner locus of this function (i.e. the points at which the minimum is attained at least twice) is the tropical hypersurface defined by $\text{trop}(f)$.

The theorem of Newton-Kapranov states that this tropical hypersurface is the same as if one computes pointwise the valuation of the hypersurface given by f . The analogue holds true if one replaces one equation f by an ideal I . A constructive proof of the theorem is given by an adapted version of the Newton-Puiseux algorithm. The hard part is to find a point in the variety over $C\{\{t\}\}$ which corresponds to a given point in the tropical variety.

It is the purpose of this library to provide basic means to deal with tropical varieties. Of course we cannot represent the field of Puiseux series over C in its full strength, however, in order to compute interesting examples it will be sufficient to replace the complex numbers C by the rational numbers Q and to replace Puiseux series in t by rational functions in t , i.e. we replace $C\{\{t\}\}$ by $Q(t)$, or sometimes even by $Q[t]$. Note, that this in particular forbids rational exponents for the t 's.

Moreover, in Singular no negative exponents of monomials are allowed, so that the integer vectors v_i will have to have non-negative entries. Shifting all exponents by a fixed integer vector does not change the tropicalisation nor does it change the toric variety. Thus this does not cause any restriction.

If, however, for some reason you prefer to work with general v_i , then you have to pass right away to the tropicalisation of the equations, wherever this is allowed – these are linear polynomials where the constant coefficient corresponds to the valuation of the original coefficient and where the non-constant coefficient correspond to the exponents of the monomials, thus they may be rational numbers respectively negative numbers: e.g. if $f = t^{1/2} x^{-2} y^3 + 2t x y + 4$ then $\text{trop}(f) = \min\{1/2x + 3y, 1 + x + y, 0\}$.

The main tools provided in this library are as follows:

- `tropicalLifting` implements the constructive proof of the Theorem of Newton-Kapranov and constructs a point in the variety over $\mathbb{C}\{\{t\}\}$ corresponding to a given point in the corresponding tropical variety associated to an ideal I ; the generators of I have to be in the polynomial ring $\mathbb{Q}[t, x_1, \dots, x_n]$ considered as a subring of $\mathbb{C}\{\{t\}\}[x_1, \dots, x_n]$; a solution will be constructed up to given order; note that several field extensions of \mathbb{Q} might be necessary throughout the intermediate computations; the procedures use the external program `gfan`
- `puiseuxExpansion` computes a Newton-Puiseux expansion of a plane curve singularity
- `drawTropicalCurve` visualises a tropical plane curve either given by a polynomial in $\mathbb{Q}(t)[x, y]$ or by a list of linear polynomials of the form $ax+by+c$ with a, b in \mathbb{Z} and c in \mathbb{Q} ; latex must be installed on your computer
- `tropicalJInvariant` computes the tropical j-invariant of a tropical elliptic curve

Procedures for tropical lifting: Procedures for drawing tropical curves: General procedures: Procedures for latex conversion: Auxiliary procedures: Procedures from binary library:

D.13.6.1 tropicalLifting

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `tropicalLifting(i, w, ord[, opt])`; i ideal, w intvec, ord int, opt string

Assume:

- i is an ideal in $\mathbb{Q}[t, x_1, \dots, x_n]$, $w = (w_0, w_1, \dots, w_n)$ and $(w_1/w_0, \dots, w_n/w_0)$ is in the tropical variety of i , and ord is the order up to which a point in $V(i)$ over $\mathbb{Q}\{\{t\}\}$ lying over $(w_1/w_0, \dots, w_n/w_0)$ shall be computed;
- w_0 may NOT be ZERO
- the basering should not have any parameters on its own and it should have a global monomial ordering, e.g. `ring r=0,(t,x(1..n)),dp;`
- the first variable of the basering will be treated as the parameter t in the Puiseux series field
- the optional parameter `opt` should be one or more strings among the following:
 - 'isZeroDimensional' : the dimension i is zero (not to be checked);
 - 'isPrime' : the ideal is prime over $\mathbb{Q}(t)[x_1, \dots, x_n]$ (not to be checked);
 - 'isInTrop' : $(w_1/w_0, \dots, w_n/w_0)$ is in the tropical variety (not to be checked);
 - 'oldGfan' : uses `gfan` version 0.2.1 or less
 - 'findAll' : find all solutions of a zero-dimensional ideal over $(w_1/w_0, \dots, w_n/w_0)$
 - 'noAbs' : do NOT use absolute primary decomposition
 - 'puiseux' : $n=1$ and i is generated by one equation
 - 'noResubst' : avoids the computation of the resubstitution

Return: IF THE OPTION 'findAll' WAS NOT SET THEN:
list, containing one lifting of the given point $(w_1/w_0, \dots, w_n/w_0)$ in the tropical variety of i to a point in $V(i)$ over Puiseux series field up to the first ord terms; more precisely:
IF THE OPTION 'noAbs' WAS NOT SET, THEN:

```
l[1] = ring Q[a]/m[[t]]
```

```
l[2] = int
```

```
l[3] = intvec
```

```
l[4] = list
```

```
IF THE OPTION 'noAbs' WAS SET, THEN:
```

```
l[1] = ring Q[X(1),...,X(k)]/m[[t]]
```

```
l[2] = int
```

```
l[3] = intvec
```

```
l[4] = list
```

```
l[5] = string
```

```
IF THE OPTION 'findAll' WAS SET, THEN:
```

list, containing ALL liftings of the given point $((w_1/w_0, \dots, w_n/w_0))$ in the tropical variety of i to a point in $V(i)$ over Puiseux series field up to the first ord terms, if the ideal is zero-dimensional over $\mathbb{Q}\{\{t\}\}$;

more precisely, each entry of the list is a list l as computed if 'findAll' was NOT set

WE NOW DESCRIBE THE LIST ENTRIES IF 'findAll' WAS NOT SET:

- the ring $l[1]$ contains an ideal LIFT, which contains a point in $V(i)$ lying over w up to the first ord terms;

- and if the integer $l[2]$ is N then t has to be replaced by $t^{1/N}$ in the lift, or alternatively replace t by t^N in the defining ideal

- if the $k+1$ st entry of $l[3]$ is non-zero, then the k th component of LIFT has to be multiplied $t^{(-l[3][k]/l[3][1])}$ AFTER substituting t by $t^{1/N}$

- unless the option 'noResubst' was set, the k th entry of list $l[4]$ is a string which represents the k th generator of

the ideal i where the coordinates have been replaced by the result of the lift;

the t -order of the k th entry should in principle be larger than the t -degree of LIFT

- if the option 'noAbs' was set, then the string in $l[5]$ defines a maximal ideal in the field $\mathbb{Q}[X(1), \dots, X(k)]$, where $X(1), \dots, X(k)$ are the parameters of the ring in $l[1]$;

the basefield of the ring in $l[1]$ should be considered modulo this ideal

Remark:

- it is best to use the procedure `displayTropicalLifting` to display the result

- the option 'findAll' cannot be used if 'noAbs' is set

- if the parameter 'findAll' is set AND the ideal i is zero-dimensional in $\mathbb{Q}\{\{t\}\}[x_1, \dots, x_n]$ then ALL points in $V(i)$ lying over w are computed up to order ord; if the ideal is not-zero dimensional, then only the points in the ideal after cutting down to dimension zero will be computed

- the procedure requires that the program GFAN is installed on your computer; if you have GFAN version less than 0.3.0 then you must use the optional parameter 'oldGfan'

- the procedure requires the Singular procedure `absPrimdecGTZ` to be present in the package `primdec.lib`, unless the option 'noAbs' is set; but even if `absPrimdecGTZ` is present it might be necessary to set the option 'noAbs' in order to avoid the costly absolute primary decomposition; the side effect is that the field extension which is computed throughout the recursion might need more than one parameter to be described

- since \mathbb{Q} is infinite, the procedure finishes with probability one

- you can call the procedure with $\mathbb{Z}/p\mathbb{Z}$ as base field instead of \mathbb{Q} , but there are some problems you should be aware of:

- + the Puiseux series field over the algebraic closure of $\mathbb{Z}/p\mathbb{Z}$ is NOT algebraically closed, and thus there may not exist a point in $V(i)$ over the Puiseux series field with the desired valuation; so there is no chance that the procedure produced a sensible

output - e.g. if $i = tx^p - tx - 1$
 + if the dimension of i over $\mathbb{Z}/p\mathbb{Z}(t)$ is not zero the process of reduction to zero might not work if the characteristic is small and you are unlucky
 + the option 'noAbs' has to be used since absolute primary decomposition in Singular only works in characteristic zero
 - the basefield should either be \mathbb{Q} or $\mathbb{Z}/p\mathbb{Z}$ for some prime p ; field extensions will be computed if necessary; if you need parameters or field extensions from the beginning they should rather be simulated as variables possibly adding their relations to the ideal; the weights for the additional variables should be zero

D.13.6.2 displayTropicalLifting

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `displaytropcallifting(troplift[,#]);` troplift list, # list

Assume: troplift is the output of `tropicalLifting`; the optional parameter # can be the string 'subst'

Return: none

Note: - the procedure displays the output of the procedure `tropicalLifting`
 - if the optional parameter 'subst' is given, then the lifting is substituted into the ideal and the result is displayed

Example:

```

LIB "tropical.lib";
ring r=0,(t,x,y,z),dp;
ideal i=-y2t4+x2,yt3+xz+y;
intvec w=2,-4,0,4;
displayTropicalLifting(tropicalLifting(i,w,3),"subst");

```

```

⇒ i[2]=0

```

D.13.6.3 `puiseuxExpansion`

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `puiseuxExpansion(f,n,#)`; f poly, n int, # list

Assume: f is a non-constant polynomial in two variables which is not divisible by the first variable and which is squarefree as a power series over the complex numbers; the base field is either the field of rational numbers or a finite extension thereof; monomial ordering is assumed to be local; the optional parameter # can be the string 'subst'

Return: list, where each entry of the list l describes the Newton-Puiseux parametrisations of one branch of the plane curve singularity at the origin defined by f; only the terms up to order n of each parametrisation are computed
 $l[i][1]$ = is a ring
 $l[i][2]$ = int
 $l[i][3]$ = string

WE NOW DESCRIBE THE LIST ENTRIES $l[i]$ IN MORE DETAIL:

- the ring $l[i][1]$ contains an ideal LIFT and the Newton-Puiseux parametrisation of the branch is given by $x=t^N$ and $y=LIFT[1]$, where $N=l[i][2]$
- if the base field had a parameter and a minimal polynomial, then the new base field will have a parameter and a new minimal polynomial, and $LIFT[2]$ describes how the

old parameter can be computed from the new one

- if a field extension with minimal polynomial of degree k was necessary, then to the one extension produced actually k extensions correspond by replacing the parameter a successively by all zeros of the minimal polynomial
- if the option `subst` was set `l[i][3]` contains the polynomial where y has been substituted by $y(t^{1/N})$ as a string

Remark:

- it is best to use the procedure `displayPuisseuxExpansion` to display the result
- the procedure requires the Singular procedure `absPrimdecGTZ` to be present in the package `primdec.lib`
- if f is not squarefree it will be replaced by its squarefree part

Example:

```
LIB "tropical.lib";
printlevel=1;
ring r=0,(x,y),ds;
poly f=x2-y4+x5y7;
puisseuxExpansion(f,3,"subst");
⇒ // ** name conflict var(1) and var(3): 'x(1)', rename to '@x(1)' in >> \
    ring EXTENSIONRING = ring(RL);<<
⇒ in tropical.lib::findzerosAndBasictransform:6334
⇒ The procedure has created a list of lists. The jth entry of this list

⇒

```

D.13.6.5 tropicalCurve

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `tropicalCurve(tp[,#]);` tp list, # optional list

Assume: tp is list of linear polynomials of the form $ax+by+c$ with integers a, b and a rational number c representing a tropical Laurent polynomial defining a tropical plane curve; alternatively tp can be a polynomial in $\mathbb{Q}(t)[x,y]$ defining a tropical plane curve via the valuation map; the basering must have a global monomial ordering, two variables and up to one parameter!

Return: list, each entry $i=1,\dots,\text{size}(l)-1$ corresponds to a vertex in the tropical plane curve defined by tp
 $l[i][1]$ = x-coordinate of the ith vertex
 $l[i][2]$ = y-coordinate of the ith vertex
 $l[i][3]$ = intmat, if j is an entry in the first row of intmat then the ith vertex of the tropical curve is connected to the jth vertex with multiplicity given by the corresponding entry in the second row
 $l[i][4]$ = list of lists, the first entry of a list is a primitive integer vector defining the direction of an unbounded edge emerging from the ith vertex of the graph, the corresponding second entry in the list is the multiplicity of the unbounded edge
 $l[i][5]$ = a polynomial whose monomials mark the vertices in the Newton polygon corresponding to the entries in tp which take the common minimum at the ith vertex – if some coefficient a or b of the linear polynomials in the input was negative, then each monomial has to be shifted by the values in $l[\text{size}(l)][3]$
 $l[\text{size}(l)][1]$ = list, the entries describe the boundary points of the Newton subdivision
 $l[\text{size}(l)][2]$ = list, the entries are pairs of integer vectors defining an interior edge of the Newton subdivision
 $l[\text{size}(l)][3]$ = intvec, the monomials occurring in $l[i][5]$ have to be shifted by this vector

in order to represent marked
vertices in the Newton polygon

Note: here the tropical polynomial is supposed to be the MINIMUM of the linear forms in tp , unless the optional input $\# [1]$ is the string 'max'

Example:

```
LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
poly f=t*(x7+y7+1)+1/t*(x4+y4+x2+y2+x3y+xy3)+1/t7*x2y2;
list graph=tropicalCurve(f);
// the tropical curve has size(graph)-1 vertices
size(graph)-1;
⇒ 7
// the coordinates of the first vertex are graph[1][1],graph[1][2];
graph[1][1],graph[1][2];
⇒ -8/3 -8/3
// the first vertex is connected to the vertices
// graph[1][3][1,1..ncols(graph[1][3])]
intmat M=graph[1][3];
M[1,1..ncols(graph[1][3])];
⇒ 2 3
// the weights of the edges to these vertices are
// graph[1][3][2,1..ncols(graph[1][3])]
M[2,1..ncols(graph[1][3])];
⇒ 1 1
// from the first vertex emerge size(graph[1][4]) unbounded edges
size(graph[1][4]);
⇒ 1
// the primitive integral direction vector of the first unbounded edge
// of the first vertex
graph[1][4][1][1];
⇒ -1,-1
// the weight of the first unbounded edge of the first vertex
graph[1][4][1][2];
⇒ 7
// the monomials which are part of the Newton subdivision of the first vertex
graph[1][5];
⇒ x7+y7+x2y2

// the boundary of the Newton polytope
graph[size(graph)][1];
⇒ [1]:
⇒ 0,7
⇒ [2]:
⇒ 7,0
⇒ [3]:
⇒ 0,0
// an entry in graph[size(graph)][2] is a pair of points
// in the Newton polytope bounding an inner edge
graph[size(graph)][2][1];
⇒ [1]:
⇒ 7,0
⇒ [2]:
```

\mapsto 2,2

D.13.6.6 drawTropicalCurve

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `drawTropicalCurve(f[,#]);` `f` poly or list, `#` optional list

Assume: `f` is list of linear polynomials of the form $ax+by+c$ with integers a , b and a rational number c representing a tropical Laurent polynomial defining a tropical plane curve; alternatively `f` can be a polynomial in $\mathbb{Q}(t)[x,y]$ defining a tropical plane curve via the valuation map;
the basering must have a global monomial ordering, two variables and up to one parameter!

Return: NONE

Note:

- the procedure creates the files `/tmp/tropicalcurveNUMBER.tex` and `/tmp/tropicalcurveNUMBER.ps`, where `NUMBER` is a random four digit integer; moreover it displays the tropical curve via `xdg-open`;
- if you wish to remove all these files from `/tmp`, call the procedure `cleanTmp`
- edges with multiplicity greater than one carry this multiplicity
- if `#` is empty, then the tropical curve is computed w.r.t. minimum, if `#[1]` is the string 'max', then it is computed w.r.t. maximum
- if the last optional argument is 'onlytexfile' then only the latex file is produced; this option should be used if `xdg-utils` is not installed on your system
- note that lattice points in the Newton subdivision which are black correspond to markings of the marked subdivision, while lattice points in grey are not marked

Example:

```
LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
poly f=t*(x3+y3+1)+1/t*(x2+y2+x+y+x2y+xy2)+1/t2*xy;
// the command drawTropicalCurve(f) computes the graph of the tropical curve
// given by f and displays a post script image, provided you have xdg-open
drawTropicalCurve(f);

D.13.6.7 drawNewtonSubdivision

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

- Usage:** `drawTropicalCurve(f[,#]);` f poly, $\#$ optional list
- Assume:** f is list of linear polynomials of the form $ax+by+c$ with integers a, b and a rational number c representing a tropical Laurent polynomial defining a tropical plane curve; alternatively f can be a polynomial in $\mathbb{Q}(t)[x,y]$ defining a tropical plane curve via the valuation map;
the basering must have a global monomial ordering, two variables and up to one parameter!
- Return:** NONE
- Note:**
- the procedure creates the files `/tmp/newtonsubdivisionNUMBER.tex`, and `/tmp/newtonsubdivisionNUMBER.ps`, where `NUMBER` is a random four digit integer;
 - moreover it displays the tropical curve defined by f via `xdg-open`; if you wish to remove all these files from `/tmp`, call the procedure `cleanTmp`;
 - if $\#$ is empty, then the tropical curve is computed w.r.t. minimum, if $\#[1]$ is the string 'max', then it is computed w.r.t. maximum
 - note that lattice points in the Newton subdivision which are black correspond to markings of the marked subdivision, while lattice points in grey are not marked

Example:

```
LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
poly f=t*(x3+y3+1)+1/t*(x2+y2+x+y+x2y+xy2)+1/t2*xy;
// the command drawTropicalCurve(f) computes the graph of the tropical curve
// given by f and displays a post script image, provided you have xdg-open
drawNewtonSubdivision(f);

D.13.6.8 tropicalJInvariant

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `tropicalJInvariant(f[,#]);` `f` poly or list, `#` optional list

Assume: `f` is list of linear polynomials of the form $ax+by+c$ with integers a , b and a rational number c representing a tropical Laurent polynomial defining a tropical plane curve; alternatively `f` can be a polynomial in $\mathbb{Q}(t)[x,y]$ defining a tropical plane curve via the valuation map; the basering must have a global monomial ordering, two variables and up to one parameter!

Return: number, if the graph underlying the tropical curve has precisely one loop then its weighted lattice length is returned, otherwise the result will be -1

Note:

- if the tropical curve is elliptic and its embedded graph has precisely one loop, then the weighted lattice length of the loop is its tropical j -invariant
- the procedure checks if the embedded graph of the tropical curve has genus one, but it does NOT check if the loop can be resolved, so that the curve is not a proper tropical elliptic curve
- if the embedded graph of a tropical elliptic curve has more than one loop, then all but one can be resolved, but this is not observed by this procedure, so it will not compute

the j-invariant

- if # is empty, then the tropical curve is computed w.r.t. minimum, if #[1] is the string 'max', then it is computed w.r.t. maximum
- the tropicalJInvariant of a plane tropical cubic is the 'cycle length' of the cubic as introduced in the paper: Eric Katz, Hannah Markwig, Thomas Markwig: The j-invariant of a cubic tropical plane curve.

Example:

```
LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
// tropicalJInvariant computes the tropical j-invariant of an elliptic curve
tropicalJInvariant(t*(x3+y3+1)+1/t*(x2+y2+x+y+x2y+xy2)+1/t2*xy);
⇒ 6
// the Newton polygon need not be the standard simplex
tropicalJInvariant(x+y+x2y+xy2+1/t*xy);
⇒ 8
// the curve can have arbitrary degree
tropicalJInvariant(t*(x7+y7+1)+1/t*(x4+y4+x2+y2+x3y+xy3)+1/t7*x2y2);
⇒ 14/3
// the procedure does not realise, if the embedded graph of the tropical
// curve has a loop that can be resolved
tropicalJInvariant(1+x+y+xy+tx2y+txy2);
⇒ 4
// but it does realise, if the curve has no loop at all ...
tropicalJInvariant(x+y+1);
⇒ The embedded graph of the curve has not genus one.
⇒ -1
// or if the embedded graph has more than one loop - even if only one
// cannot be resolved
tropicalJInvariant(1+x+y+xy+tx2y+txy2+t3x5+t3y5+tx2y2+t2xy4+t2yx4);
⇒ The embedded graph of the curve has not genus one.
⇒ -1
```

D.13.6.9 weierstrassForm

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

D.13.6.10 conicWithTangents

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `conicWithTangents(points[,#]);` points list, # optional list

Assume: points is a list of five points in the plane over $K(t)$

Return: list, $l[1]$ = the list points of the five given points
 $l[2]$ = the conic f passing through the five points
 $l[3]$ = list of equations of tangents to f in the given points
 $l[4]$ = ideal, tropicalisation of f (i.e. list of linear forms)
 $l[5]$ = a list of the tropicalisation of the tangents
 $l[6]$ = a list containing the vertices of the tropical conic f
 $l[7]$ = a list containing lists with vertices of the tangents
 $l[8]$ = a string which contains the latex-code to draw the tropical conic and its tropicalised tangents

$l[9]$ = if $\#$ is non-empty, this is the same data for the dual conic and the points dual to the computed tangents

Note: the points must be generic, i.e. no three on a line

Example:

```
LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
// the input consists of a list of five points in the plane over Q(t)
list points=list(1/t^2,t),list(1/t,t^2),list(1,1),list(t,1/t^2),list(t^2,1/t);

D.13.6.11 tropicalise

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `tropicalise(f[#]);` f polynomial, $\#$ optional list

Assume: f is a polynomial in $\mathbb{Q}(t)[x_1, \dots, x_n]$

Return: list, the linear forms of the tropicalisation of f

Note: if $\#$ is empty, then the valuation of t will be 1,
 if $\#$ is the string 'max' it will be -1;
 the latter supposes that we consider the maximum of the computed linear forms, the
 former that we consider their minimum

Example:

```

LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
tropicalise(2t3x2-1/t*xy+2t3y2+(3t3-t)*x+ty+(t6+1));

↪ [6]:
↪ 0

```

D.13.6.12 tropicaliseSet

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `tropicaliseSet(i);` i ideal

Assume: i is an ideal in $\mathbb{Q}(t)[x_1, \dots, x_n]$

Return: list, the j th entry is the tropicalisation of the j th generator of i

Example:

```

LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
ideal i=txy-y2+1,2t3x2+1/t*y-t6;

```

```

tropicaliseSet(i);
⇨ [1]:
⇨ [1]:
⇨ x+y+1
⇨ [2]:
⇨ 2*y
⇨ [3]:
⇨ 0
⇨ [2]:
⇨ [1]:
⇨ 2*x+3
⇨ [2]:
⇨ y-1
⇨ [3]:
⇨ 6

```

D.13.6.13 tInitialForm

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `tInitialForm(f,w)`; f a polynomial, w an integer vector

Assume: f is a polynomial in $\mathbb{Q}[t, x_1, \dots, x_n]$ and $w=(w_0, w_1, \dots, w_n)$

Return: `poly`, the t -initialform of $f(t, x)$ w.r.t. w evaluated at $t=1$

Note: the t -initialform is the sum of the terms with MAXIMAL weighted order w.r.t. w

Example:

```

LIB "tropical.lib";
ring r=0,(t,x,y),dp;
poly f=t4x2+y2-t2xy+t4x-t9;
intvec w=-1,-2,-3;
tInitialForm(f,w);
⇨ y2+x

```

D.13.6.14 tInitialIdeal

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `tInitialIdeal(i,w)`; i ideal, w intvec

Assume: i is an ideal in $\mathbb{Q}[t, x_1, \dots, x_n]$ and $w=(w_0, \dots, w_n)$

Return: `ideal ini`, the t -initial ideal of i with respect to w

Example:

```

LIB "tropical.lib";
ring r=0,(t,x,y),dp;
ideal i=t2x-y+t3,t2x-y-2t3x;
intvec w=-1,2,0;
// the t-initial forms of the generators are
tInitialForm(i[1],w),tInitialForm(i[2],w);
⇨ x-y x-y
// and they do not generate the t-initial ideal of i
tInitialIdeal(i,w);

```

```

 $\mapsto$   $\_ [1] = -x + y$ 
 $\mapsto$   $\_ [2] = 2xy$ 
 $\mapsto$   $\_ [3] = 2x$ 
 $\mapsto$   $\_ [4] = 2xy^2$ 

```

D.13.6.15 initialForm

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `initialForm(f,w)`; f a polynomial, w an integer vector

Assume: f is a polynomial in $\mathbb{Q}[x_1, \dots, x_n]$ and $w = (w_1, \dots, w_n)$

Return: `poly`, the initial form of $f(x)$ w.r.t. w

Note: the `initialForm` consists of the terms with MAXIMAL weighted order w.r.t. w

Example:

```

LIB "tropical.lib";
ring r=0,(x,y),dp;
poly f=x3+y2-xy+x-1;
intvec w=2,3;
initialForm(f,w);
 $\mapsto$   $x^3 + y^2$ 

```

D.13.6.16 initialIdeal

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `initialIdeal(i,w)`; i ideal, w intvec

Assume: i is an ideal in $\mathbb{Q}[x_1, \dots, x_n]$ and $w = (w_1, \dots, w_n)$

Return: `ideal`, the `initialIdeal` of i w.r.t. w

Note: the `initialIdeal` consists of the terms with MAXIMAL weighted order w.r.t. w

Example:

```

LIB "tropical.lib";
ring r=0,(x,y),dp;
poly f=x3+y2-xy+x-1;
intvec w=2,3;
initialIdeal(f,w);
 $\mapsto$   $\_ [1] = x^3 + y^2$ 

```

D.13.6.17 texNumber

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `texNumber(f)`; f poly

Return: string, tex command representing leading coefficient of f using `\frac`

Example:

```

LIB "tropical.lib";
ring r=(0,t),x,dp;
texNumber((3t2-1)/t3);
 $\mapsto$  \tfrac{-1+3\cdot t^2}{t^3}

```

D.13.6.18 texPolynomial

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `texPolynomial(f); f poly`

Return: string, the tex command representing `f`

Example:

```
LIB "tropical.lib";
ring r=(0,t),x,dp;
texPolynomial(1/t*x^2-t^2x+1/t);
⇒ \tfrac{1}{t}\cdot x^2-t^2\cdot x+\tfrac{1}{t}
```

D.13.6.19 texMatrix

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `texMatrix(M); M matrix`

Return: string, the tex command representing `M`

Example:

```
LIB "tropical.lib";
ring r=(0,t),x,dp;
matrix M[2][2]=3/2,1/t*x^2-t^2x+1/t,5,-2x;
texMatrix(M);
⇒ \left(\begin{array}{cc}
⇒ \tfrac{3}{2} & \tfrac{1}{t}\cdot x^2-t^2\cdot x+\tfrac{1}{t} \\
⇒ 5 & -2\cdot x \\
⇒ \end{array}\right)
```

D.13.6.20 texDrawBasic

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `texDrawBasic(texdraw); list texdraw`

Assume: `texdraw` is a list of strings representing `texdraw` commands (as produced by `texDrawTropical`) which should be embedded into a `texdraw` environment

Return: string, a `texdraw` environment enclosing the input

Note: is called from `conicWithTangents`

Example:

```
LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
poly f=x+y+1;
string texf=texDrawTropical(tropicalCurve(f),list("",1));
texDrawBasic(texf);
⇒
⇒ \begin{texdraw}
⇒ \drawdim cm \relunitscale 0.7 \arrowheadtype t:V
⇒ %\linewidth 0.05 \lpatt (0.1 0.4)
⇒ %\move (-4 0) \avec (9 0) \move (0 -4) \avec (0 9)
⇒ \linewidth 0.1 \lpatt (1 0)
⇒
```

```

⇒
⇒      \setgray 0.6
⇒
⇒
⇒
⇒      \relunitscale 12
⇒      \move (0 0) \fcir f:0 r:0.016
⇒      \move (0 0) \rlvec (0 0.25)
⇒      \move (0 0) \rlvec (0.25 0)
⇒      \move (0 0) \rlvec (-0.25 -0.25)
⇒
⇒      %% HERE STARTS THE CODE FOR THE LATTICE
⇒      \move (0 0) \fcir f:0.8 r:0.008
⇒      %% HERE ENDS THE CODE FOR THE LATTICE
⇒
⇒      \end{texdraw}

```

D.13.6.21 texDrawTropical

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `texDrawTropical(graph[,#]);` graph list, # optional list

Assume: graph is the output of `tropicalCurve`

Return: string, the texdraw code of the tropical plane curve encoded by graph

Note:

- if the list # is non-empty, the first entry should be a string; if this string is 'max', then the tropical curve is considered with respect to the maximum
- the procedure computes a scalefactor for the texdraw command which should help to display the curve in the right way; this may, however, be a bad idea if several `texDrawTropical` outputs are put together to form one image; the scalefactor can be prescribed by the further optional entry of type poly
- one can add a string as last optional argument to the list #; it can be used to insert further texdraw commands (e.g. to have a lighter image as when called from inside `conicWithTangents`);
- the list # is optional and may as well be empty

Example:

```

LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
poly f=x+y+x2y+xy2+1/t*xy;
list graph=tropicalCurve(f);
// compute the texdraw code of the tropical curve defined by f
texDrawTropical(graph);
⇒
⇒
⇒      \setgray 0.6
⇒
⇒
⇒      \relunitscale 6
⇒      \move (-1 -1) \fcir f:0 r:0.03
⇒      \move (-1 -1) \lvec (-1 1)
⇒      \move (-1 -1) \lvec (1 -1)
⇒      \move (-1 -1) \rlvec (-0.5 -0.5)
⇒      \move (-1 1) \fcir f:0 r:0.03

```

```

⇒      \move (-1 1) \lvec (1 1)
⇒      \move (-1 1) \rlvec (-0.5 0.5)

⇒

```

D.13.6.22 texDrawNewtonSubdivision

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `texDrawNewtonSubdivision(graph[,#]);` graph list, # optional list

Assume: graph is the output of `tropicalCurve`

Return: string, the texdraw code of the Newton subdivision of the tropical plane curve encoded by graph

Note:

- the list # may contain optional arguments, of which only one will be considered, namely the first entry of type 'poly'; this entry should be a rational number which specifies the scaling factor to be used; if it is missing, the factor will be computed; the list # may as well be empty
- note that lattice points in the Newton subdivision which are black correspond to markings of the marked subdivision, while lattice points in grey are not marked

Example:

```
LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
poly f=x+y+x2y+xy2+1/t*xy;
list graph=tropicalCurve(f);
// compute the texdraw code of the Newton subdivision of the tropical curve
texDrawNewtonSubdivision(graph);

⇒

```

D.13.6.23 texDrawTriangulation

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `texDrawTriangulation(triang,polygon);` triang,polygon list

Assume: polygon is a list of integer vectors describing the lattice points of a marked polygon;
 triang is a list of integer vectors describing a triangulation of the marked polygon
 in the sense that an integer vector of the form (i,j,k) describes the triangle formed by polygon[i], polygon[j] and polygon[k]

Return: string, a texdraw code for the triangulation described by triang without the texdraw environment

Example:

```

LIB "tropical.lib";
// the lattice polygon spanned by the points (0,0), (3,0) and (0,3)
// with all integer points as markings
list polygon=intvec(1,1),intvec(3,0),intvec(2,0),intvec(1,0),intvec(0,0),
intvec(2,1),intvec(0,1),intvec(1,2),intvec(0,2),intvec(0,3);
// define a triangulation by connecting the only interior point
//      with the vertices
list triang=intvec(1,2,5),intvec(1,5,10),intvec(1,2,10);
// produce the texdraw output of the triangulation triang
texDrawTriangulation(triang,polygon);
⇒
⇒      \drawdim cm \relunitscale 1.2 \arrowheadtype t:V

↳      \move (0 3)
↳      \fcir f:0.7 r:0.04

```

D.13.6.24 radicalMemberShip

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `radicalMemberShip (f,i);` f poly, i ideal

Return: `int`, 1 if f is in the radical of i , 0 else

Example:

```

LIB "tropical.lib";
ring r=0,(x,y),dp;
ideal i=(x+1)*y2;
// y is NOT in the radical of i
radicalMemberShip(y,i);
↳ 0
ring rr=0,(x,y),ds;
ideal i=(x+1)*y2;
// since this time the ordering is local, y is in the radical of i
radicalMemberShip(y,i);
↳ 1

```

D.13.6.25 tInitialFormPar

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `tInitialFormPar(f,w)`; f a polynomial, w an integer vector
Assume: f is a polynomial in $\mathbb{Q}(t)[x_1, \dots, x_n]$ and $w=(w_1, \dots, w_n)$
Return: poly, the t -initialform of $f(t,x)$ w.r.t. $(1,w)$ evaluated at $t=1$
Note: the t -initialform are the terms with MINIMAL weighted order w.r.t. $(1,w)$

Example:

```
LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
poly f=t4x2+y2-t2xy+t4x-t9;
intvec w=2,3;
tInitialFormPar(f,w);
↦ y2+x
```

D.13.6.26 tInitialFormParMax

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `tInitialFormParMax(f,w)`; f a polynomial, w an integer vector
Assume: f is a polynomial in $\mathbb{Q}(t)[x_1, \dots, x_n]$ and $w=(w_1, \dots, w_n)$
Return: poly, the t -initialform of $f(t,x)$ w.r.t. $(-1,w)$ evaluated at $t=1$
Note: the t -initialform are the terms with MAXIMAL weighted order w.r.t. $(1,w)$

Example:

```
LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
poly f=t4x2+y2-t2xy+t4x-1/t6;
intvec w=2,3;
tInitialFormParMax(f,w);
↦ y2-1
```

D.13.6.27 solveTInitialFormPar

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `solveTInitialFormPar(i)`; i ideal
Assume: i is a zero-dimensional ideal in $\mathbb{Q}(t)[x_1, \dots, x_n]$ generated by the $(1,w)$ -homogeneous elements for some integer vector w - i.e. by the $(1,w)$ -initialforms of polynomials
Return: none
Note: the procedure just displays complex approximations of the solution set of i

Example:

```
LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
ideal i=t2x2+y2,x-t2;
solveTInitialFormPar(i);
↦ [1]:
↦ [1]:
↦ 1
↦ [2]:
```

```

⇒ -i
⇒ [2]:
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ i
⇒ [1]:
⇒ // coefficients: real[i](complex:8 digits, additional 8 digits)/(i^2+1\
)
⇒ // number of vars : 2
⇒ //          block 1 : ordering lp
⇒ //          : names x y
⇒ //          block 2 : ordering C

```

D.13.6.28 detropicalise

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `detropicalise(f);` `f` poly or `f` list

Assume: if `f` is of type `poly` then `t` is a linear polynomial with an arbitrary constant term and positive integer coefficients as further coefficients;
if `f` is of type `list` then `f` is a list of polynomials of the type just described in before

Return: `poly`, the detropicalisation of `f` ignoring the constant parts

Note: the output will be a monomial and the constant coefficient has been ignored

Example:

```

LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
detropicalise(3x+4y-1);
⇒ x3y4

```

D.13.6.29 tDetropicalise

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `tDetropicalise(f);` `f` poly or `f` list

Assume: if `f` is of type `poly` then `f` is a linear polynomial with an integer constant term and positive integer coefficients as further coefficients;
if `f` is of type `list` then it is a list of polynomials of the type just described in before

Return: `poly`, the detropicalisation of `f` over the field $\mathbb{Q}(t)$

Note: the output will be a term where the coefficient is a Laurent monomial in the variable `t`

Example:

```

LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
tDetropicalise(3x+4y-1);
⇒ 1/(t)*x3y4

```

D.13.6.30 dualConic

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `dualConic(f);` f poly

Assume: f is an affine conic in two variables x and y

Return: `poly`, the equation of the dual conic

Example:

```
LIB "tropical.lib";
ring r=0,(x,y),dp;
poly conic=2x2+1/2y2-1;
dualConic(conic);
↦ 1/2x2+2y2-1
```

D.13.6.31 parameterSubstitute

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `parameterSubstitute(f,N);` f poly, N int

Assume: f is a polynomial in $Q(t)[x_1, \dots, x_n]$ describing a plane curve over $Q(t)$

Return: `poly` f with t replaced by t^N

Example:

```
LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
poly f=t2xy+1/t*y+t3;
parameterSubstitute(f,3);
↦ (t6)*xy+1/(t3)*y+(t9)
parameterSubstitute(f,-1);
↦ 1/(t2)*xy+(t)*y+1/(t3)
```

D.13.6.32 tropicalSubst

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `parameterSubstitute(f,N,L);` f poly, N int, L list

Assume: f is a polynomial in $Q(t)[x_1, \dots, x_k]$
and L is a list of the form `var(i.1),poly_1,...,v(i.k),poly_k`

Return: list, the list is the tropical polynomial which we get from f by replacing the i -th variable be the i -th polynomial but in the i -th polynomial the parameter t is replaced by $t^{1/N}$

Example:

```
LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
poly f=t2x+1/t*y-1;
tropicalSubst(f,2,x,x+t,y,tx+y+t2);
↦ [1]:
↦ x-1/2
↦ [2]:
↦ y-1
```

```

⇒ [3]:
⇒ 5/2
// The procedure can be used to study the effect of a transformation of
// the form  $x \rightarrow x+t^b$ , with  $b$  a rational number, on the tropicalisation and
// the  $j$ -invariant of a cubic over the Puiseux series.
f=t7*y3+t3*y2+t*(x3+xy2+y+1)+xy;
// -  $b=3/2$ , then the cycle length of the tropical cubic equals  $-\text{val}(j\text{-inv})$ 
list g32=tropicalSubst(f,2,x,x+t3,y,y);
tropicalJInvariant(g32);
⇒ 5
// -  $b=1$ , then it is still true, but only just ...
list g1=tropicalSubst(f,1,x,x+t,y,y);
tropicalJInvariant(g1);
⇒ 5
// -  $b=2/3$ , as soon as  $b<1$ , the cycle length is strictly less than  $-\text{val}(j\text{-inv})$ 
list g23=tropicalSubst(f,3,x,x+t2,y,y);
tropicalJInvariant(g23);
⇒ 14/3

```

D.13.6.33 randomPolyInT

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `randomPolyInT(d,ug,og[#]);` d , ug , og int, $\#$ list

Assume: the basering has a parameter t

Return: `poly`, a polynomial of degree d where the coefficients are of the form t^j with j a random integer between ug and og

Note: if an optional argument $\#$ is given, then the coefficients are instead either of the form t^j as above or they are zero, and this is chosen randomly

Example:

```

LIB "tropical.lib";
ring r=(0,t),(x,y),dp;
randomPolyInT(3,-2,5);
⇒ (t5)*x3+1/(t2)*x2y+(t3)*xy2+(t4)*y3+1/(t)*x2+(t5)*xy+y2+1/(t2)*x+1/(t)*y+\
1
randomPolyInT(3,-2,5,1);
⇒ (t4)*y3+1/(t)*x2+(t2)*xy+(t2)*y2+(t3)*x

```

D.13.6.34 cleanTmp

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `cleanTmp()`

Purpose: some procedures create latex and ps-files in the directory `/tmp`; in order to remove them simply call `cleanTmp()`;

Return: none

D.13.6.35 groebnerCone

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `groebnerCone(I,w)`; I ideal or poly, w intvec or bigintmat

Assume: I a reduced standard basis and w contained in the maximal Groebner cone

Return: cone, the Groebner cone of I with respect to w

Example:

```
LIB "tropical.lib";
ring r = 0,(x,y,z),dp;
ideal I = cyclic(3);
option(redSB);
ideal stdI = std(I);
// w lies in the interior of a maximal Groebner cone
intvec w = 3,2,1;
cone CwI = groebnerCone(stdI,w);
print(rays(CwI));
⇒ 1,1,0,
⇒ 1,0,0,
⇒ 1,1,1
// v lies on a facet of a maximal Groebner cone
intvec v = 2,1,0;
cone CvI = groebnerCone(stdI,v);
print(rays(CvI));
⇒ 1,0,0,
⇒ 1,1,0
// v lies on a ray of a maximal Groebner cone
intvec u = 1,1,1;
cone CuI = groebnerCone(stdI,u);
print(rays(CuI));
⇒ 1,1,1
```

D.13.6.36 maximalGroebnerCone

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `maximalGroebnerCone(I)`; I ideal or poly

Assume: I a reduced standard basis

Return: cone, the maximal Groebner cone of I with respect to the current ordering

Example:

```
LIB "tropical.lib";
ring r = 0,(x,y,z),dp;
ideal I = cyclic(3);
option(redSB);
ideal stdI = std(I);
cone CI = maximalGroebnerCone(stdI);
print(rays(CI));
⇒ 1,1,0,
⇒ 1,0,0,
⇒ 1,1,1
ring s = 0,(x,y,z,u),dp;
ideal Ih = homog(cyclic(3),u);
ideal stdI = std(Ih);
cone CIh = maximalGroebnerCone(stdI);
```

```

print(rays(CIh));
↪ 1, 1,-1,-1,
↪ 3,-1,-1,-1,
↪ 1, 1, 1,-3
print(generatorsOfLinealitySpace(CIh));
↪ -1,-1,-1,-1
ring rw = 0,(x,y,z),(a(1,0,1),lp);
ideal I = cyclic(3);
ideal stdI = std(I);
CI = maximalGroebnerCone(stdI);
print(rays(CI));
↪ 1,0,0,
↪ 1,0,1,
↪ 1,1,1

```

D.13.6.37 homogeneitySpace

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `homogeneitySpace(I)`; I ideal or poly

Assume: I a reduced standard basis

Return: cone, the set of all weight vectors with respect to whom I is weighted homogeneous

Example:

```

LIB "tropical.lib";
ring r = 0,(x,y,z),dp;
ideal I = cyclic(3);
option(redSB);
ideal stdI = std(I);
cone COI = homogeneitySpace(stdI);
print(generatorsOfLinealitySpace(COI));
↪
ring s = 0,(x,y,z,u),dp;
ideal Ih = homog(cyclic(3),u);
ideal stdI = std(Ih);
cone COIh = homogeneitySpace(stdI);
print(generatorsOfLinealitySpace(COIh));
↪ -1,-1,-1,-1

```

D.13.6.38 initial

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\], page 2143](#)).

Usage: `initial(f,w)`; f poly, w intvec or bigintmat
`initial(I,w)`; I ideal, w intvec or bigintmat

Assume: I reduced Groebner basis,
w in the maximal Groebner cone of I with respect to the current ordering

Return: poly or ideal, the initial form of f or the initial ideal of I with respect to w

Example:

```

LIB "tropical.lib";
ring r = 0,(x,y,z),dp;

```

```

ideal I = cyclic(3);
intvec w = 1,1,1;
option(redSB);
ideal stdI = std(I);
stdI;
↳ stdI[1]=x+y+z
↳ stdI[2]=y2+yz+z2
↳ stdI[3]=z3-1
ideal inI = initial(stdI,w);
inI;
↳ inI[1]=x+y+z
↳ inI[2]=y2+yz+z2
↳ inI[3]=z3

```

D.13.6.39 tropicalVariety

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `tropicalVariety(f[p]);` f poly, p optional number
 `tropicalVariety(I[p]);` I ideal, p optional number

Assume: I homogeneous, p prime number

Return: fan, the tropical variety of f resp. I with respect to the trivial valuation or the p-adic valuation

Note: set `printlevel=1` for output during traversal

Example:

```

LIB "tropical.lib";
ring r = 0,(x,y,z,w),dp;
ideal I = x-2y+3z,3y-4z+5w;
tropicalVariety(I);

D.13.6.40 groebnerFan

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `groebnerFan(f); f poly`
 `groebnerFan(I); I ideal`

Assume: `I` homogeneous

Return: `fan`, the Groebner fan of `f` resp. `I`

Note: set `printlevel=1` for output during traversal

Example:

```

LIB "tropical.lib";
ring r = 0,(x,y,z,w),dp;
ideal I = x-2y+3z,3y-4z+5w;
groebnerFan(I);

D.13.6.41 groebnerComplex

Procedure from library `tropical.lib` (see [Section D.13.6 \[tropical.lib\]](#), page 2143).

Usage: `groebnerComplex(f,p)`; `f` poly, `p` number
 `groebnerComplex(I,p)`; `I` ideal, `p` number

Assume: `I` homogeneous, `p` prime number

Return: `fan`, the Groebner complex of `f` resp. `I` with respect to the p -adic valuation

Note: set `printlevel=1` for output during traversal

Example:

```

LIB "tropical.lib";
ring r = 0,(x,y,z,w),dp;
ideal I = x-2y+3z,3y-4z+5w;
groebnerComplex(I,number(2));

D.13.7 tropicalNewton_lib

Library: tropicalNewton.lib

Purpose: Computations in Tropical Geometry using Newton Polygon methods

Authors: Tommy Hofman, email: thofmann@mathematik.uni.kl.de Yue Ren, email: reny@cs.bgu.ac.il

Overview: This libraries contains algorithms for computing

- non-trivial points on tropical varieties,
- zero-dimensional tropical varieties,
- one-codimensional links of tropical varieties

based on Newton polygon methods.

References:

Hofmann, Ren: Computing tropical points and tropical links, arXiv:1611.02878 (WARNING: this library follows the max convention instead and triangular sets follow the definition of the Singular book)

Procedures: See also: [Section D.13.6.39 \[tropicalVariety\]](#), page 2182; [Section D.13.6 \[tropical_lib\]](#), page 2143.

D.13.7.1 setUniformizingParameter

Procedure from library tropicalNewton.lib (see [Section D.13.7 \[tropicalNewton_lib\]](#), page 2199).

Usage: setUniformizingParameter(p); p number

Return: none, sets the uniformizing parameter as p

Assume: char(K)==0 and p prime number or
trdeg(K)>0 and p transcendental variable or
p==0

Example:

```

LIB "tropicalNewton.lib";
// poor man's polynomials over Puiseux series:
ring r = (0,t),x,dp;
setUniformizingParameter(t);
val(t2+t3);
↳ 2
val(t^-2+t^-3);
↳ -3
// poor man's polynomials over p-adic numbers:
ring s = 0,x,dp;

```

```

setUniformizingParameter(2);
val(12);
 $\mapsto$  2
val(1/12);
 $\mapsto$  -2

```

D.13.7.2 val

Procedure from library `tropicalNewton.lib` (see [Section D.13.7 \[tropicalNewton.lib\], page 2199](#)).

Usage: `val(c)`; c number

Return: int, the valuation of a element in the ground field

Assume: `uniformizingParameter` is set and $c \neq 0$

Example:

```

LIB "tropicalNewton.lib";
// poor man's polynomials over Puiseux series:
ring r = (0,t),x,dp;
setUniformizingParameter(t);
val(t2+t3);
 $\mapsto$  2
val(t^-2+t^-3);
 $\mapsto$  -3
// poor man's polynomials over p-adic numbers:
ring s = 0,x,dp;
setUniformizingParameter(2);
val(12);
 $\mapsto$  2
val(1/12);
 $\mapsto$  -2

```

D.13.7.3 newtonPolygonNegSlopes

Procedure from library `tropicalNewton.lib` (see [Section D.13.7 \[tropicalNewton.lib\], page 2199](#)).

Usage: `newtonPolygonNegSlopes(g,b)`; g poly, b int

Return: list, the negative slopes of the Newton Polygon of g
if $b=1$, computes root (type poly) instead if (easily) possible

Assume: `uniformizingParameter` is set and g univariate

Example:

```

LIB "tropicalNewton.lib";
ring r = (0,t),x,dp;
setUniformizingParameter(t);
poly g = tx2+x+1;
newtonPolygonNegSlopes(g);
 $\mapsto$  [1]:
 $\mapsto$  0
 $\mapsto$  [2]:
 $\mapsto$  -1
// poor man's polynomials over p-adic numbers:
ring s = 0,x,dp;
setUniformizingParameter(3);

```

```

poly g = x2+9x+1;
newtonPolygonNegSlopes(g);
↳ [1]:
↳ 0

```

D.13.7.4 cccMatrixToPositiveIntvec

Procedure from library `tropicalNewton.lib` (see [Section D.13.7 \[tropicalNewton.lib\], page 2199](#)).

Usage: `cccMatrixToPositiveIntvec(M)`; M matrix

Return: intvec, strictly positive equivalent as weight vector to row vector in M

Assume: constant coefficient case only,
will scale weight vector and add vectors of ones to it

Example:

```

LIB "tropicalNewton.lib";
ring r = (0,t),(p01,p02,p12,p03,p13,p23,p04,p14,p24,p34),dp;
number uniformizingParameter = t;
export(uniformizingParameter);
ideal I =
p23*p14-p13*p24+p12*p34,
p23*p04-p03*p24+p02*p34,
p13*p04-p03*p14+p01*p34,
p12*p04-p02*p14+p01*p24,
p12*p03-p02*p13+p01*p23;
system("--random",1337);
matrix p = tropicalPointNewton(I);
print(p);
↳ -59,-14,-87,57,-16,-63,41,-32,-90,-8
intvec w = cccMatrixToPositiveIntvec(p);
print(w);
↳ 32,
↳ 77,
↳ 4,
↳ 148,
↳ 75,
↳ 28,
↳ 132,
↳ 59,
↳ 1,
↳ 83
def s = switchRingsAndComputeInitialIdeal(I,w);
kill uniformizingParameter;

```

D.13.7.5 tropicalPointNewton

Procedure from library `tropicalNewton.lib` (see [Section D.13.7 \[tropicalNewton.lib\], page 2199](#)).

Usage: `tropicalPointsLasVegas(I)`; I ideal

Return: matrix, a matrix containing a tropical point as row vector

Assume: uniformizingParameter is set and I monomial free

Note: if printlevel sufficiently high will print intermediate data and timings returns error if randomly chosen hyperplanes are not generic

Example:

```
LIB "tropicalNewton.lib";
ring r = (0,t),(p01,p02,p12,p03,p13,p23,p04,p14,p24,p34),dp;
number uniformizingParameter = t;
export(uniformizingParameter);
ideal I =
p23*p14-p13*p24+p12*p34,
p23*p04-p03*p24+p02*p34,
p13*p04-p03*p14+p01*p34,
p12*p04-p02*p14+p01*p24,
p12*p03-p02*p13+p01*p23;
system("--random",1337);
printlevel = 3;
matrix p = tropicalPointNewton(I);

D.13.7.6 switchRingsAndComputeInitialIdeal

Procedure from library `tropicalNewton.lib` (see [Section D.13.7 \[tropicalNewton.lib\]](#), page 2199).

Usage: `switchRingsAndComputeInitialIdeal(I,w);` I ideal, w intvec

Return: ring, a ring containing the initial ideal with respect to w

Assume: constant coefficient case and w strictly positive integer

Note: if printlevel sufficiently high will print timing

Example:

```

LIB "tropicalNewton.lib";
ring r = (0,t),(p01,p02,p12,p03,p13,p23,p04,p14,p24,p34),dp;

D.13.7.7 tropicalVarietyNewton

Procedure from library `tropicalNewton.lib` (see [Section D.13.7 \[tropicalNewton.lib\]](#), page 2199).

Usage: `tropicalVarietyNewton(I);` I ideal

Return: matrix, a matrix containing all elements of the tropical variety

Assume: `uniformizingParameter` is set, I monomial free and zero-dimensional

Example:

```

LIB "tropicalNewton.lib";
ring r = (0,t),(z,y,x),lp;
number uniformizingParameter = t;
export(uniformizingParameter);
ideal I = tx2+x+1,txy2+xy+1,xyz+1;
list TI = tropicalVarietyNewton(I);
for (int i=1; i<=size(TI); i++)

```

```

{ print(TI[i]); }
↪ 0,0,0
↪ 0,-1,1
↪ -1,1,0
↪ -2,1,1
kill uniformizingParameter;

```

D.13.7.8 tropicalLinkNewton

Procedure from library `tropicalNewton.lib` (see [Section D.13.7 \[tropicalNewton.lib\]](#), page 2199).

Usage: `tropicalLinkNewton(inI)`; `inI` ideal

Return: matrix, a matrix containing generators of all rays of the tropical variety

Assume: constant coefficient case, `inI` is monomial free,
its tropical variety has codimension one lineality space and is a polyhedral fan

Note: if `printlevel` sufficiently high will print intermediate results

Example:

```

LIB "tropicalNewton.lib";
// a 10 valent facet in tropical Grass(3,7)
ring r = (0,t),
(p012,p013,p023,p123,p014,p024,p124,p034,p134,p234,
p015,p025,p125,p035,p135,p235,p045,p145,p245,p345,
p016,p026,p126,p036,p136,p236,p046,p146,p246,p346,
p056,p156,p256,p356,p456),
wp(4,7,5,7,4,4,4,7,5,7,2,1,2,4,4,4,2,1,2,4,7,5,7,7,
5,7,7,5,7,4,4,4,4,4,4);
number uniformizingParameter = t;
export(uniformizingParameter);
ideal inI =

D.14 Miscellaneous libraries

D.14.1 arr_lib

Library: arr.lib

Purpose: a library of algorithms for arrangements of hyperplanes

Authors: Randolph Scholz (rscholz@rhrk.uni-kl.de),
 Patrick Serwene (serwene@mathematik.uni-kl.de),
 Lukas Kuehne (lf.kuehne@gmail.com)

Overloads:

```

// OPERATORS
= arrAdd assignment
+ arrAdd union of two arrs
[ arrGet access to a single/multiple hyperplane(s) - arrMinus deletes given hyperplanes
from the arr <= arrLEQ comparison
>= arrGEQ comparison
== arrEQ comparison
!= arrNEQ comparison
< arrLNEQ comparison
> arrGNEQ comparison
// TYPECASTING
matrix arr2mat coeff matrix
poly arr2poly defining polynomial
// OTHER
variables arrVariables ideal generated by the variables the arr depends on nvars arrN-
vars number of variables the arr depends on delete arrDelete deletes hyperplanes by
indices print arrPrint prints the arr on the screen

```

```
// IDEAL INHERITED FUNCTIONS
homog arrHomog checks if arrangement is homogeneous simplify arrSimplify simplifies
arrangement size arrSize number of planes
subst arrSubst substitute variables
// MULTI-ARRANGEMENTS
= multarrAdd assignment of multarr
+ multarrAdd union of multarr
poly multarr2poly defining polynomial
size multarrSize number of hyperplanes with mult. print multarrPrint displays multiarr
delete multarrDelete deletes hyperplane
```

Procedures:**D.14.1.1 arrSet**

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\], page 2208](#)).

Usage: `arrSet(A, k, p);` arr A, int k, poly p;

Return: [arr] Arrangement where the k-th hyperplane is replaced by p.

Note: p must be linear

Example:

```
LIB "arr.lib";
ring R = 0, (x,y,z), dp;
arr A = ideal(x,y,z);
arrSet(A,1,x+1);
⇨ _[1]=x+1
⇨ _[2]=y
⇨ _[3]=z
⇨
```

D.14.1.2 type2arr

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\], page 2208](#)).

Usage: `type2arr(#);` # def

Return: [arr] Arrangement defined by the input

Note: The procedure tries to cast the input to [arr] using `arrAdd`

Example:

```
LIB "arr.lib";
ring R = 0, (x,y,z), dp;
ideal I = x,y,z;
typeof(type2arr(I));
⇨ arr
```

D.14.1.3 mat2arr

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\], page 2208](#)).

Usage: `mat2arr(M);` matrix (M|b)

Return: [arr] interprets the rows of the matrix as the defining polynomial equations of the arrangement where the last column will be considered as the constant terms, i.e. if M is an $m \times (n+1)$ matrix we have $H_i = \text{Ker}(M_{i1}x_1 + \dots + M_{in}x_n + M_{i(n+1)})$ for $i=1\dots m$ and $A = \{H_1, \dots, H_m\}$ the resulting arrangement.

Example:

```
LIB "arr.lib";
ring R = 0,(x,y,z),dp;
matrix M[4][4] = 1,0,1,1,1,1,0,2,0,1,1,3,2,1,1,4;
print(M);
  ↳ 1,0,1,1,
  ↳ 1,1,0,2,
  ↳ 0,1,1,3,
  ↳ 2,1,1,4
mat2arr(M);
  ↳ _[1]=x+z+1
  ↳ _[2]=x+y+2
  ↳ _[3]=y+z+3
  ↳ _[4]=2x+y+z+4
  ↳
```

See also: [Section D.14.1.4 \[mat2carr\]](#), page 2210.

D.14.1.4 mat2carr

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `mat2carr(M);` matrix M

Return: [arr] interprets the rows of the matrix as the defining polynomial equations of the arrangement. I.e. if M is an $m \times n$ matrix we have $H_i = \text{Ker}(M_{i1}x_1 + \dots + M_{in}x_n)$ for $i=1\dots m$ and $A = \{H_1, \dots, H_m\}$ the resulting arrangement.

Example:

```
LIB "arr.lib";
ring R = 0,(x,y,z),dp;
matrix M[4][3] = 1,0,1,1,1,0,0,1,1,2,1,1;
print(M);
  ↳ 1,0,1,
  ↳ 1,1,0,
  ↳ 0,1,1,
  ↳ 2,1,1
mat2carr(M);
  ↳ _[1]=x+z
  ↳ _[2]=x+y
  ↳ _[3]=y+z
  ↳ _[4]=2x+y+z
  ↳
```

See also: [Section D.14.1.3 \[mat2arr\]](#), page 2209.

D.14.1.5 arrPrintMatrix

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arPrintMatrix(arr A)`
Return: `[]` prints arr in matrix form
Note: differs `print(matrix(arr A))` since variables included

Example:

```
LIB "arr.lib";
ring R = 0,(x,y,z),dp;
arr A = mat2arr(random(20,5,4));
A;
⇒ _[1]=10x+y-2z-12
⇒ _[2]=2x-16z-14
⇒ _[3]=11y+16z-5
⇒ _[4]=-16x-18y-5z+11
⇒ _[5]=3x+8y+6
⇒
arrPrintMatrix(A);
⇒ 10x, y, -2z, -12,
⇒ 2x, 0, -16z, -14,
⇒ 0, 11y, 16z, -5,
⇒ -16x, -18y, -5z, 11,
⇒ 3x, 8y, 0, 6
```

D.14.1.6 varMat

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `varMat(v); v intvec`
Return: `[matrix]` M containing the corresponding ring-variables

Example:

```
LIB "arr.lib";
ring R = 0,(x(1..6)),dp;
intvec v = 2,4,6;
varMat(v);
⇒ _[1,1]=x(2)
⇒ _[2,1]=x(4)
⇒ _[3,1]=x(6)
```

See also: [Section D.14.1.9 \[arrLastVar\]](#), page 2212; [Section D.14.1.8 \[arrSwapVar\]](#), page 2212; [Section D.14.1.6 \[varMat\]](#), page 2211; [Section D.14.1.7 \[varNum\]](#), page 2211.

D.14.1.7 varNum

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `varnum(string s);`
 `varnum(ring-variable);`
Return: `[int]` number of given ring variable, or 0 if it does not appear
Note: This procedure has the same functionality as `varNum` from the `dmod.lib` package, but also accepts polys as input.

Example:

```

LIB "arr.lib";
ring R = 0,(x,y,z),dp;
varNum(y);
↳ 2
ring S = 0,(x(1..5),y(1..5)),dp;
varNum("y(3)");
↳ 8

```

See also: [Section D.14.1.9 \[arrLastVar\]](#), page 2212; [Section D.14.1.8 \[arrSwapVar\]](#), page 2212; [Section D.14.1.6 \[varMat\]](#), page 2211; [Section D.14.1.7 \[varNum\]](#), page 2211.

D.14.1.8 arrSwapVar

Procedure from library `arr.lib` (see [Section D.14.1 \[arr_lib\]](#), page 2208).

Usage: `arrSwapVar(A, i, j);` arr A, ring_variables/integers i,j

Return: [arr] A where variables i and j are swapped.

Note: if i and/or j are integers the algorithm considers the variables `variables(A)[i]` and/or `variables(A)[j]`

Example:

```

LIB "arr.lib";
ring R = 0,(x,y,z),lp;
arr A = ideal(x+1,x+y,z);
arrSwapVar(A,x,z);
↳ _[1]=z+1
↳ _[2]=y+z
↳ _[3]=x
↳

```

See also: [Section D.14.1.9 \[arrLastVar\]](#), page 2212; [Section D.14.1.8 \[arrSwapVar\]](#), page 2212; [Section D.14.1.6 \[varMat\]](#), page 2211; [Section D.14.1.7 \[varNum\]](#), page 2211.

D.14.1.9 arrLastVar

Procedure from library `arr.lib` (see [Section D.14.1 \[arr_lib\]](#), page 2208).

Usage: `arrLastVar(A);` arr A

Return: [int] number of the last variable A uses

Note: useful if you want a list containing all variables `x_1 ... x_k` used in A, but you do not want to skip any like `variables(A)` does.

Example:

```

LIB "arr.lib";
ring R = 0,x(1..10),dp;
arr A = ideal(x(1), x(2), x(3), x(6));
int n = arrLastVar(A);
varMat(1..n);
↳ _[1,1]=x(1)
↳ _[2,1]=x(2)
↳ _[3,1]=x(3)
↳ _[4,1]=x(4)
↳ _[5,1]=x(5)
↳ _[6,1]=x(6)

```

```

variables(A);
↪ _[1]=x(1)
↪ _[2]=x(2)
↪ _[3]=x(3)
↪ _[4]=x(6)

```

See also: [Section D.14.1.9 \[arrLastVar\]](#), page 2212; [Section D.14.1.8 \[arrSwapVar\]](#), page 2212; [Section D.14.1.6 \[varMat\]](#), page 2211; [Section D.14.1.7 \[varNum\]](#), page 2211.

D.14.1.10 arrCenter

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrCenter(A); arr A`

Return: [list] L entry 0 if A not centered or entries 1, x, H, where x is any particular point of the center and H is a matrix consisting of vectors which spanning linear intersection space.

If there is exactly one solution, then $H = 0$.

Note: The intersection of all hyperplanes can be expressed in forms of a linear system $Ax=b$, where $(A|b)$ is the coeff. matrix of the arrangement, which is then solved using L-U decomposition

Example:

```

LIB "arr.lib";
ring R = 0,(x,y,z),dp;
arr A= ideal(x,y,x-y+1);    // centerless
arrCenter(A);
↪ [1]:
↪    0
arr B= ideal(x,y,z);        // center is a single point
arrCenter(B);
↪ [1]:
↪    1
↪ [2]:
↪    _[1,1]=0
↪    _[2,1]=0
↪    _[3,1]=0
↪ [3]:
↪    _[1,1]=0
arr C= ideal(x,z,x+z);      // center is a line
// here we get a wrong result because the matrix is simplified since A doesn't
// contain any "y" the matrix (A|b) will be 3x3 only.
arrCenter(C);
↪ [1]:
↪    1
↪ [2]:
↪    _[1,1]=0
↪    _[2,1]=0
↪    _[3,1]=0
↪ [3]:
↪    _[1,1]=0
↪    _[2,1]=-1
↪    _[3,1]=0

```

See also: [Section D.14.1.10 \[arrCenter\]](#), page 2213; [Section D.14.1.12 \[arrCentered\]](#), page 2214; [Section D.14.1.11 \[arrCentral\]](#), page 2214; [Section D.14.1.13 \[arrCentralize\]](#), page 2215.

D.14.1.11 arrCentral

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrCentral(A);` arr A

Return: `[0,1]` true if arr is central (i.e. all planes intersect in 0)

Note: This is the same as `homog(A)`

Example:

```
LIB "arr.lib";
ring R = 0,(x,y,z),dp;
// centered and central
arr A = ideal(x,y,z);
arrCentered(A);
⇒ 1
arrCentral(A);
⇒ 1
// centered but not central (center: (-1,-1/2, 1))
arr B = ideal(x+1,2y+1,-z+1);
arrCentered(B);
⇒ 1
arrCentral(B);
⇒ 0
```

See also: [Section D.14.1.10 \[arrCenter\]](#), page 2213; [Section D.14.1.12 \[arrCentered\]](#), page 2214; [Section D.14.1.11 \[arrCentral\]](#), page 2214; [Section D.14.1.13 \[arrCentralize\]](#), page 2215.

D.14.1.12 arrCentered

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrCentered(A);` arr A

Return: `[0,1]` true if A is centered (i.e. intersection of all planes not empty)

Note: The algorithm uses the rank of matrix: $Ax=b$ has a solution iff $\text{rank}(A) = \text{rank}(A|b)$

Example:

```
LIB "arr.lib";
ring R = 0,(x,y,z),dp;
arr A= ideal(x,y,x-y+1);           // centerless
arrCentral(A);
⇒ 0
arr B= ideal(x,y,z);               // central with center being the origin
arrCentral(B);
⇒ 1
arr C= ideal(x+1,2y+1,-z+1);       // central with center (-1,-1/2, 1)
arrCentral(C);
⇒ 0
```

See also: [Section D.14.1.10 \[arrCenter\]](#), page 2213; [Section D.14.1.12 \[arrCentered\]](#), page 2214; [Section D.14.1.11 \[arrCentral\]](#), page 2214; [Section D.14.1.13 \[arrCentralize\]](#), page 2215.

D.14.1.13 arrCentralize

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrCentralize(A); arr A`

Return: `[arr]` A after centralization via coordinate change

Note: The coordinate change only does translation, vector of translation is the second output of `arrCenter`

Example:

```
LIB "arr.lib";
ring R = 0,(x,y,z),dp;
arr A = ideal(x-1,y,x-z-1,x-z-1);
arrCentralize(A);
↳ _[1]=x-2
↳ _[2]=y
↳ _[3]=x-z-2
↳
```

See also: [Section D.14.1.10 \[arrCenter\]](#), page 2213; [Section D.14.1.12 \[arrCentered\]](#), page 2214; [Section D.14.1.11 \[arrCentral\]](#), page 2214; [Section D.14.1.13 \[arrCentralize\]](#), page 2215.

D.14.1.14 arrCoordChange

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrCoordChange(A, T); arr A, (m*n mat) n*n or n*n+1 matrix T arrCoordChange(A, T, c); arr A, n*n matrix T, n*1 matrix/vector`

Return: `[arr]`: Arrangement A `[A|b]` after a coordinate change $f: x \rightarrow Tx + c$ with T invertible i.e. $[A|b] \Rightarrow [AT^{-1}|b+AT^{-1}c]$ since we have $f(H) = f(\ker(a_1x_1 + \dots + a_nx_n - b)) = \{f(x) : a'x - b = 0\} = \{y : a'f^{-1}(y) - b = 0\} = \{y : a'(T^{-1}(y-c)) - b = 0\} = \{y : a'T^{-1}y - (b + a'T^{-1}c) = 0\}$

Note: There are 3 options how you can give the input (in each case $n \leq \text{nvars}(\text{basering})$) 1. Just a $n \times n$ matrix with \Rightarrow Will automatically complete T by a unit matrix and perform $x \rightarrow Tx$ 2. A $n \times n$ matrix T and a $n \times 1$ vector/matrix c with \Rightarrow Will automatically complete T and c and perform $x \rightarrow Tx + c$ 3. A $n \times n+1$ matrix T with \Rightarrow will use last column as translation vector c

Example:

```
LIB "arr.lib";
ring r = 0,(x,y,z),lp;
arr A = x,y,z;
arrCoordChange(A,1,[0,0,1]); //lifts z-hyperplane by 1 unit
↳ _[1]=x
↳ _[2]=y
↳ _[3]=z-1
↳
matrix T[2][2] = [0,1,1,0]; // swaps x and y
arrCoordChange(A,T);
↳ _[1]=y
```

```

  ↪ _[2]=x
  ↪ _[3]=z
  ↪
  matrix c[2][1] = [1,0];
  T = concat(T,c);           // now swap x and y and add 1 to x afterwards
  arrCoordChange(A,T);
  ↪ _[1]=y
  ↪ _[2]=x-1
  ↪ _[3]=z
  ↪
  // Note how T doesn't even need to be a full 3x3 base change matrix.

```

See also: [Section D.14.1.14 \[arrCoordChange\], page 2215](#); [Section D.14.1.15 \[arrCoordNormalize\], page 2216](#).

D.14.1.15 arrCoordNormalize

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\], page 2208](#)).

Usage: `arrCoordChange(A, v);`

Return: `[arr]`: Arrangement after a coordinate change that transforms the arrangement such that after a transformation $x \rightarrow Tx + c$ we have the arrangement has the matrix representation $[AT^{-1}|b+AT^{-1}c]$ such that $[AT^{-1}]_v = I$ and $[b+AT^{-1}c]_v = 0$;

Note: algorithm performs a base change if H_k is homogeneous (i.e. has no) constant term and an affine transformation otherwise
 $Ax+b = 0$, Transformation $x = Ty+c$: $AT^{-1}y + AT^{-1}c + b = 0$ Now we want to have $(AT^{-1})_v = I$ and $(AT^{-1}c + b)_v = AT^{-1}_v * c + b_v = 0$

Example:

```

LIB "arr.lib";
ring r = 0,(x,y,z),lp;
arr A = ideal(x,y,z,x+z+4);
intvec v = 1,2,4;
arrCoordNormalize(A,v);
↪ _[1]=x
↪ _[2]=y
↪ _[3]=-x+z-4
↪ _[4]=z
↪

```

See also: [Section D.14.1.14 \[arrCoordChange\], page 2215](#); [Section D.14.1.15 \[arrCoordNormalize\], page 2216](#).

D.14.1.16 arrCone

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\], page 2208](#)).

Usage: `arrCone(A);`
`arrCone(A, ring_variable);` `arr` `A` arrangement in variables `x_1...x_n`;

Return: `arr`, the coned hyperplane Arrangement `cA` with respect to the given `ring_variable`, or the last `ring_variable` if none was given.

Note: The hyperplanes are homogenized w.r.t. `v` and a new hyperplane $H = \ker(x_{n+1})$ is added.

Example:

```

LIB "arr.lib";
ring R = 0,(x,y,z),dp;
arr A = ideal(x+1, x,x-2,x-1);
arrCone(A, y);
  ↳ _[1]=x+y
  ↳ _[2]=x
  ↳ _[3]=x-2y
  ↳ _[4]=x-y
  ↳ _[5]=y
  ↳
arr B= ideal(x,y,x+y-1);
arrCone(B);
  ↳ _[1]=x
  ↳ _[2]=y
  ↳ _[3]=x+y-z
  ↳ _[4]=z
  ↳

```

See also: [Section D.14.1.16 \[arrCone\]](#), page 2216; [Section D.14.1.17 \[arrDecone\]](#), page 2217; [Section D.14.1.21 \[arrEssentialize\]](#), page 2219; [Section D.14.1.20 \[arrIsEssential\]](#), page 2219; [Section D.14.1.19 \[arrRestrict\]](#), page 2218.

D.14.1.17 arrDecone

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrDecone(A, k)`; arrangement A, integer k;

Return: `arr`: the deconed hyperplane Arrangement dA

Note: A has to be non-empty and central. `arrDecone` is an inverse operation to `arrCone` since $A == \text{arrDecone}(\text{arrCone}(A), \text{size}(A)+1)$ for any A. One can also decone a central arrangement with respect to any hyper- plane k, but than a coordinate change is necessary to make $H_k = \ker(x_k)$. Since such a coordinate change is not unique, use `arrCoordchange` to do so.

Example:

```

LIB "arr.lib";
ring R = 0,(x,y,z),dp;
arr A= ideal(x,y,z,x+y-z);
arrDecone(A,3);
  ↳ _[1]=x
  ↳ _[2]=y
  ↳ _[3]=x+y-1
  ↳

```

See also: [Section D.14.1.16 \[arrCone\]](#), page 2216; [Section D.14.1.17 \[arrDecone\]](#), page 2217; [Section D.14.1.21 \[arrEssentialize\]](#), page 2219; [Section D.14.1.20 \[arrIsEssential\]](#), page 2219; [Section D.14.1.19 \[arrRestrict\]](#), page 2218.

D.14.1.18 arrLocalize

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrLocalize(A, v)`; arrangement A, intvec v;

Return: arr: the localized arrangement A_X , i.e. A_X only contains the hyperplanes which contain the flat X , which is defined by the equations $A[v]$

Example:

```
LIB "arr.lib";
ring R = 0,(x,y,z),dp;
arr A=arrTypeB(3);
intvec v=5,8;
arr B=arrLocalize(A,v);
B;
↳ _[1]=x-y
↳ _[2]=x+y
↳ _[3]=x
↳ _[4]=y
↳
```

See also: [Section D.14.1.16 \[arrCone\]](#), page 2216; [Section D.14.1.17 \[arrDecone\]](#), page 2217; [Section D.14.1.21 \[arrEssentialize\]](#), page 2219; [Section D.14.1.20 \[arrIsEssential\]](#), page 2219; [Section D.14.1.19 \[arrRestrict\]](#), page 2218.

D.14.1.19 arrRestrict

Procedure from library `arr.lib` (see [Section D.14.1 \[arr_lib\]](#), page 2208).

Return: arr: the restricted hyperplane Arrangement (A^X)

Note: A has to be non-empty.

Remarks: We restrict A to the flat X , defined by the equations in $A[v]$. The restriction will only be performed, if the ideal defining the flat X is monomial (i.e. X is an intersection of coordinate planes). If the optional argument `CC` is given, the arrangement is transformed in such a way that X has the above form.

Example:

```
LIB "arr.lib";
ring S = 0,(x,y,z),dp;
arr A = arrTypeB(3);
A;
↳ _[1]=x-y
↳ _[2]=x+y
↳ _[3]=x-z
↳ _[4]=x+z
↳ _[5]=x
↳ _[6]=y-z
↳ _[7]=y+z
↳ _[8]=y
↳ _[9]=z
↳
arrRestrict(A,9);
↳ _[1]=x-y
↳ _[2]=x+y
↳ _[3]=x
↳ _[4]=y
↳
arrRestrict(A,4,"CC");
```

```

↳ _[1]=1/2y-z
↳ _[2]=1/2y+z
↳ _[3]=y
↳ _[4]=z
↳
intvec v=5,8;
arrRestrict(A,v);
↳ _[1]=-z
↳

```

See also: [Section D.14.1.16 \[arrCone\]](#), page 2216; [Section D.14.1.17 \[arrDecone\]](#), page 2217; [Section D.14.1.21 \[arrEssentialize\]](#), page 2219; [Section D.14.1.20 \[arrIsEssential\]](#), page 2219; [Section D.14.1.19 \[arrRestrict\]](#), page 2218.

D.14.1.20 arrIsEssential

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrIsEssential(A)`; arrangement A;

Return: boolean: 1 if arr is essential, i.e. rank of maximal element of poset is dimension

Note: A has to be non-empty.

Example:

```

LIB "arr.lib";
ring S = 0,(x,y,z),lp;
arr A = ideal(x,y,z);
arr B = ideal(x+y+z,x,y+z);
arrIsEssential(A);
↳ 1
arrIsEssential(B);
↳ 0

```

See also: [Section D.14.1.16 \[arrCone\]](#), page 2216; [Section D.14.1.17 \[arrDecone\]](#), page 2217; [Section D.14.1.21 \[arrEssentialize\]](#), page 2219; [Section D.14.1.20 \[arrIsEssential\]](#), page 2219; [Section D.14.1.19 \[arrRestrict\]](#), page 2218.

D.14.1.21 arrEssentialize

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrEssentialize(A)`; arrangement A;

Return: essential arrangement by transformation

Note: A has to be non-empty.

Example:

```

LIB "arr.lib";
ring S = 0,(x,y,z),dp;
arr A=arrBraid(3);
arrEssentialize(A);
↳ _[1]=x-y
↳ _[2]=x
↳ _[3]=y
↳
arr B = ideal(x+y+z,x,y+z);

```

```

arrEssentialize(B);
↪ _[1]=x+y
↪ _[2]=x
↪ _[3]=y
↪

```

See also: [Section D.14.1.16 \[arrCone\]](#), page 2216; [Section D.14.1.17 \[arrDecone\]](#), page 2217; [Section D.14.1.21 \[arrEssentialize\]](#), page 2219; [Section D.14.1.20 \[arrIsEssential\]](#), page 2219; [Section D.14.1.19 \[arrRestrict\]](#), page 2218.

D.14.1.22 arrBoolean

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrBoolean(v); int v`

Return: `arr`, which uses the first `v` variables of ring for boolean arrangement

Example:

```

LIB "arr.lib";
ring R = 0,x(1..10),dp;
arrBoolean(7);
↪ _[1]=x(1)
↪ _[2]=x(2)
↪ _[3]=x(3)
↪ _[4]=x(4)
↪ _[5]=x(5)
↪ _[6]=x(6)
↪ _[7]=x(7)
↪

```

D.14.1.23 arrBraid

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrBraid(v); int v`

Return: Type A (braid) arrangement of dimension `v`

Example:

```

LIB "arr.lib";
ring R = 0,x(1..10),dp;
arrBraid(7);
↪ _[1]=x(1)-x(2)
↪ _[2]=x(1)-x(3)
↪ _[3]=x(1)-x(4)
↪ _[4]=x(1)-x(5)
↪ _[5]=x(1)-x(6)
↪ _[6]=x(1)-x(7)
↪ _[7]=x(2)-x(3)
↪ _[8]=x(2)-x(4)
↪ _[9]=x(2)-x(5)
↪ _[10]=x(2)-x(6)

```

```

↳ _[11]=x(2)-x(7)
↳ _[12]=x(3)-x(4)
↳ _[13]=x(3)-x(5)
↳ _[14]=x(3)-x(6)
↳ _[15]=x(3)-x(7)
↳ _[16]=x(4)-x(5)
↳ _[17]=x(4)-x(6)
↳ _[18]=x(4)-x(7)
↳ _[19]=x(5)-x(6)
↳ _[20]=x(5)-x(7)
↳ _[21]=x(6)-x(7)
↳

```

D.14.1.24 arrTypeB

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrTypeB(v); int v`

Return: arrangement, which uses first `v` variables of ring for reflection arrangement of type B

Example:

```

LIB "arr.lib";
ring R = 0,x(1..10),dp;
arrTypeB(5);
↳ _[1]=x(1)-x(2)
↳ _[2]=x(1)+x(2)
↳ _[3]=x(1)-x(3)
↳ _[4]=x(1)+x(3)
↳ _[5]=x(1)-x(4)
↳ _[6]=x(1)+x(4)
↳ _[7]=x(1)-x(5)
↳ _[8]=x(1)+x(5)
↳ _[9]=x(1)
↳ _[10]=x(2)-x(3)
↳ _[11]=x(2)+x(3)
↳ _[12]=x(2)-x(4)
↳ _[13]=x(2)+x(4)
↳ _[14]=x(2)-x(5)
↳ _[15]=x(2)+x(5)
↳ _[16]=x(2)
↳ _[17]=x(3)-x(4)
↳ _[18]=x(3)+x(4)
↳ _[19]=x(3)-x(5)
↳ _[20]=x(3)+x(5)
↳ _[21]=x(3)
↳ _[22]=x(4)-x(5)
↳ _[23]=x(4)+x(5)
↳ _[24]=x(4)
↳ _[25]=x(5)
↳

```

D.14.1.25 arrTypeD

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrTypeD(v); int v`

Return: arrangement, which uses first v variables of ring for reflection arrangement of type D

Example:

```
LIB "arr.lib";
ring R = 0,x(1..10),dp;
arrTypeD(5);
⇨ _[1]=x(1)-x(2)
⇨ _[2]=x(1)+x(2)
⇨ _[3]=x(1)-x(3)
⇨ _[4]=x(1)+x(3)
⇨ _[5]=x(1)-x(4)
⇨ _[6]=x(1)+x(4)
⇨ _[7]=x(1)-x(5)
⇨ _[8]=x(1)+x(5)
⇨ _[9]=x(2)-x(3)
⇨ _[10]=x(2)+x(3)
⇨ _[11]=x(2)-x(4)
⇨ _[12]=x(2)+x(4)
⇨ _[13]=x(2)-x(5)
⇨ _[14]=x(2)+x(5)
⇨ _[15]=x(3)-x(4)
⇨ _[16]=x(3)+x(4)
⇨ _[17]=x(3)-x(5)
⇨ _[18]=x(3)+x(5)
⇨ _[19]=x(4)-x(5)
⇨ _[20]=x(4)+x(5)
⇨
```

D.14.1.26 arrRandom

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrRandom(n,v,N); int n,v,N`

Return: Random arrangement, where m is the number of hyperplanes, n the dimension, d the upper bound for absolute value of coefficients.

Note: You can also write `arr = random(d,m,n)` to create random arrangements

Example:

```
LIB "arr.lib";
ring R = 0,x(1..20),dp;
arrRandom(7,3,15);
```

```

↳ _[1]=2*x(1)-6*x(2)-3*x(3)+4*x(5)+x(6)-4*x(7)-3*x(8)-x(9)+x(10)-3*x(11)-6*\
x(12)-x(13)+2*x(14)-6*x(15)-4
↳ _[2]=x(1)-3*x(2)-4*x(3)-7*x(5)-3*x(6)+x(8)-3*x(9)-4*x(10)-x(11)-7*x(12)-2*\
*x(13)-3*x(14)-1
↳ _[3]=4*x(1)+2*x(2)+5*x(3)-x(4)+6*x(5)+5*x(6)-6*x(7)+5*x(8)+x(10)+3*x(11)-\
5*x(12)+2*x(13)+6*x(14)+x(15)+3
↳

```

See also: [Section D.14.1.22 \[arrBoolean\]](#), page 2220; [Section D.14.1.23 \[arrBraid\]](#), page 2220; [Section D.14.1.28 \[arrEdelmanReiner\]](#), page 2223; [Section D.14.1.26 \[arrRandom\]](#), page 2222; [Section D.14.1.24 \[arrTypeB\]](#), page 2221; [Section D.14.1.25 \[arrTypeD\]](#), page 2222.

D.14.1.27 arrRandomCentral

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrRandomCentral(d,m,n); int d,m,n`

Return: Random central arrangement, where m is the number of hyperplanes, n the dimension, d the upper bound for absolute value of coefficients.

Example:

```

LIB "arr.lib";
ring R = 0,x(1..20),dp;
arrRandomCentral(7,3,15);
↳ _[1]=2*x(1)-6*x(2)-3*x(3)+4*x(5)+x(6)-4*x(7)-3*x(8)-x(9)+x(10)-3*x(11)-6*\
x(12)-x(13)+2*x(14)-6*x(15)
↳ _[2]=-4*x(1)+x(2)-3*x(3)-4*x(4)-7*x(6)-3*x(7)+x(9)-3*x(10)-4*x(11)-x(12)-\
7*x(13)-2*x(14)-3*x(15)
↳ _[3]=-x(2)+4*x(3)+2*x(4)+5*x(5)-x(6)+6*x(7)+5*x(8)-6*x(9)+5*x(10)+x(12)+3*\
*x(13)-5*x(14)+2*x(15)
↳

```

See also: [Section D.14.1.22 \[arrBoolean\]](#), page 2220; [Section D.14.1.23 \[arrBraid\]](#), page 2220; [Section D.14.1.28 \[arrEdelmanReiner\]](#), page 2223; [Section D.14.1.26 \[arrRandom\]](#), page 2222; [Section D.14.1.24 \[arrTypeB\]](#), page 2221; [Section D.14.1.25 \[arrTypeD\]](#), page 2222.

D.14.1.28 arrEdelmanReiner

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrEdelmanReiner();`

Return: the Edelman-Reiner arrangement, which is a free arrangement but the restriction to the 6-th hyperplane is nonfree.
(i.e. counterexample for Orlik-Conjecture)

Note: the active ring must have at least five variables

Example:

```

LIB "arr.lib";
ring r=0,x(1..5),dp;
arrEdelmanReiner();
↳ _[1]=x(1)
↳ _[2]=x(2)
↳ _[3]=x(3)
↳ _[4]=x(4)

```

```

↳ _[5]=x(5)
↳ _[6]=x(1)-x(2)-x(3)-x(4)-x(5)
↳ _[7]=x(1)-x(2)-x(3)-x(4)+x(5)
↳ _[8]=x(1)-x(2)-x(3)+x(4)-x(5)
↳ _[9]=x(1)-x(2)-x(3)+x(4)+x(5)
↳ _[10]=x(1)-x(2)+x(3)-x(4)-x(5)
↳ _[11]=x(1)-x(2)+x(3)-x(4)+x(5)
↳ _[12]=x(1)-x(2)+x(3)+x(4)-x(5)
↳ _[13]=x(1)-x(2)+x(3)+x(4)+x(5)
↳ _[14]=x(1)+x(2)-x(3)-x(4)-x(5)
↳ _[15]=x(1)+x(2)-x(3)-x(4)+x(5)
↳ _[16]=x(1)+x(2)-x(3)+x(4)-x(5)
↳ _[17]=x(1)+x(2)-x(3)+x(4)+x(5)
↳ _[18]=x(1)+x(2)+x(3)-x(4)-x(5)
↳ _[19]=x(1)+x(2)+x(3)-x(4)+x(5)
↳ _[20]=x(1)+x(2)+x(3)+x(4)-x(5)
↳ _[21]=x(1)+x(2)+x(3)+x(4)+x(5)
↳

```

D.14.1.29 arrOrlikSolomon

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrOrlikSolomon(A); arr A`

Return: `[ring]` exterior Algebra E as ring with Orlik-Solomon ideal as attribute I. The Orlik-Solomon ideal is generated by the differentials of dependent tuples of hyperplanes. For a complex arrangement the quotient E/I is isomorphic to the cohomology ring of the complement of the arrangement.

Note: In order to access this ideal I activate this exterior algebra with `setring`.

Example:

```

LIB "arr.lib";
ring R = 0,(x,y,z),dp;
arr A = arrTypeB(3);
def E = arrOrlikSolomon(A);
setring E;
//The generators of the Orlik-Solomon-Ideal are:
I;
↳ I[1]=e(7)*e(8)-e(7)*e(9)+e(8)*e(9)
↳ I[2]=e(6)*e(8)-e(6)*e(9)+e(8)*e(9)
↳ I[3]=e(6)*e(7)-e(6)*e(9)+e(7)*e(9)
↳ I[4]=e(4)*e(5)-e(4)*e(9)+e(5)*e(9)
↳ I[5]=e(3)*e(5)-e(3)*e(9)+e(5)*e(9)
↳ I[6]=e(3)*e(4)-e(3)*e(9)+e(4)*e(9)
↳ I[7]=e(6)*e(7)-e(6)*e(8)+e(7)*e(8)
↳ I[8]=e(2)*e(5)-e(2)*e(8)+e(5)*e(8)
↳ I[9]=e(1)*e(5)-e(1)*e(8)+e(5)*e(8)
↳ I[10]=e(1)*e(2)-e(1)*e(8)+e(2)*e(8)
↳ I[11]=e(1)*e(4)-e(1)*e(7)+e(4)*e(7)

```

```

⇒ I[12]=e(2)*e(3)-e(2)*e(7)+e(3)*e(7)
⇒ I[13]=e(2)*e(4)-e(2)*e(6)+e(4)*e(6)
⇒ I[14]=e(1)*e(3)-e(1)*e(6)+e(3)*e(6)

```

See also: [Section D.14.1.29 \[arrOrlikSolomon\]](#), page 2224.

D.14.1.30 arrDer

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrDer(A); arr A , multarr A`

Return: [module] The module `Der(A)` of derivations of the (multi-)arrangement `A`, i.e. the derivations tangent to each hyperplane of `A` (resp. with multiplicities)

Note: This is only defined for central (multi-)arrangements

Example:

```
LIB "arr.lib";
ring R = 0,(x,y,z),dp;
arr A3 = arrBoolean(3);
arr B3 = arrTypeB(3);
arr G = ideal(x,y,z,x+y+z);
//The derivation module of the Boolean 3-arrangement:
arrDer(A3);
⇒ _[1]=z*gen(3)
⇒ _[2]=y*gen(2)
⇒ _[3]=x*gen(1)
//The derivation module of the Braid 3-arrangement:
arrDer(B3);
⇒ _[1]=x*gen(1)+y*gen(2)+z*gen(3)
⇒ _[2]=x2y*gen(2)-y3*gen(2)+x2z*gen(3)-z3*gen(3)
⇒ _[3]=x2y2z*gen(3)-x2z3*gen(3)-y2z3*gen(3)+z5*gen(3)
//The derivation module of the generic arrangement:
arrDer(G);
⇒ _[1]=x*gen(1)+y*gen(2)+z*gen(3)
⇒ _[2]=yz*gen(3)-yz*gen(2)
⇒ _[3]=xz*gen(3)+yz*gen(2)+z2*gen(3)
⇒ _[4]=xy*gen(2)+y2*gen(2)+yz*gen(2)
```

See also: [Section D.14.1.30 \[arrDer\]](#), page 2225; [Section D.14.1.32 \[arrExponents\]](#), page 2227; [Section D.14.1.31 \[arrIsFree\]](#), page 2226.

D.14.1.31 arrIsFree

Procedure from library `arr.lib` (see [Section D.14.1 \[arr_lib\]](#), page 2208).

Usage: `arrIsFree(A)`; `arr A`, `multarr A`

Return: `[0,1]` 1 if the (multi-)arrangement is free, i.e. `Der(A)` is a free module

Note: only defined for central arrangements

Example:

```
LIB "arr.lib";
ring R = 0,(x,y,z),dp;
arr A3 = arrBoolean(3);
arr B3 = arrTypeB(3);
arr G = ideal(x,y,z,x+y+z);
arrIsFree(A3);
⇒ 1
arrIsFree(B3);
⇒ 1
arrIsFree(G);
⇒ 0
```

See also: [Section D.14.1.30 \[arrDer\]](#), page 2225; [Section D.14.1.32 \[arrExponents\]](#), page 2227; [Section D.14.1.31 \[arrIsFree\]](#), page 2226.

D.14.1.32 arrExponents

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrExponents(A);` arr A, multarr A

Return: [intvec] The exponents of a free (multi-) arrangement, i.e. the degrees of a basis of $D(A)$ the derivation module.

Note: only defined for central arrangements

Example:

```
LIB "arr.lib";
ring R = 0,(x,y,z),dp;
arr A3 = arrBoolean(3);
arr B3 = arrTypeB(3);
arr G = ideal(x,y,z,x+y+z);
arrExponents(A3);
  ↪ 1,1,1
arrExponents(B3);
  ↪ 1,3,5
```

See also: [Section D.14.1.30 \[arrDer\]](#), page 2225; [Section D.14.1.32 \[arrExponents\]](#), page 2227; [Section D.14.1.31 \[arrIsFree\]](#), page 2226.

D.14.1.33 arr2multarr

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `multArrFromIntvec(arr A, intvec v);`

Return: [multarr] multiarrangement MA, which is the arrangement A with multiplicities v

Note: the size of v must match the number of hyperplanes of the arrangement A

Example:

```
LIB "arr.lib";
ring R = 0,(x,y,z),dp;
arr A = arrTypeB(3);           A;
  ↪ _[1]=x-y
  ↪ _[2]=x+y
  ↪ _[3]=x-z
  ↪ _[4]=x+z
  ↪ _[5]=x
  ↪ _[6]=y-z
  ↪ _[7]=y+z
  ↪ _[8]=y
  ↪ _[9]=z
  ↪
intvec v=2:9;                  v;
  ↪ 2,2,2,2,2,2,2,2,2
multarr MA=arr2multarr(A,v);
MA;
  ↪ _[1]=(x-y)^2
  ↪ _[2]=(x+y)^2
  ↪ _[3]=(x-z)^2
  ↪ _[4]=(x+z)^2
```

```

↳ _[5]=(x)^2
↳ _[6]=(y-z)^2
↳ _[7]=(y+z)^2
↳ _[8]=(y)^2
↳ _[9]=(z)^2
↳

```

See also: [Section D.14.1.33 \[arr2multarr\]](#), page 2227; [Section D.14.1.34 \[multarr2arr\]](#), page 2228.

D.14.1.34 multarr2arr

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `multarr2arr(multarr A, intvec v);`

Return: `[arr]` arrangement A, with all multiplicities removed

Example:

```

LIB "arr.lib";
ring r = 0,(x,y,z),dp;
multarr A=x2y3z5; A;
↳ _[1]=(x)^2
↳ _[2]=(y)^3
↳ _[3]=(z)^5
↳
arr AS = multarr2arr(A); AS;
↳ _[1]=x
↳ _[2]=y
↳ _[3]=z
↳

```

See also: [Section D.14.1.33 \[arr2multarr\]](#), page 2227; [Section D.14.1.34 \[multarr2arr\]](#), page 2228.

D.14.1.35 multarrRestrict

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Return: `[multarr]` the restricted hyperplane Multi-Arrangement (A^X) with multiplicities i.e. counting how often one element of the restricted arrangement occurs as intersection of hyperplane of the first arrangement. This definition is due to Guenter M. Ziegler.

Note: A has to be non-empty.

Remarks: We restrict A to the flat X, defined by the equations in $A[v]$. The restriction will only be performed, if the ideal defining the flat X is monomial (i.e. X is an intersection of coordinate planes). If the optional argument CC is given, the arrangement is transformed in such a way that X has the above form.

Example:

```

LIB "arr.lib";
ring R = 0,x(1..5),dp;
arr A = arrEdelmanReiner(); A;
↳ _[1]=x(1)
↳ _[2]=x(2)
↳ _[3]=x(3)
↳ _[4]=x(4)
↳ _[5]=x(5)

```

```

↳ _[6]=x(1)-x(2)-x(3)-x(4)-x(5)
↳ _[7]=x(1)-x(2)-x(3)-x(4)+x(5)
↳ _[8]=x(1)-x(2)-x(3)+x(4)-x(5)
↳ _[9]=x(1)-x(2)-x(3)+x(4)+x(5)
↳ _[10]=x(1)-x(2)+x(3)-x(4)-x(5)
↳ _[11]=x(1)-x(2)+x(3)-x(4)+x(5)
↳ _[12]=x(1)-x(2)+x(3)+x(4)-x(5)
↳ _[13]=x(1)-x(2)+x(3)+x(4)+x(5)
↳ _[14]=x(1)+x(2)-x(3)-x(4)-x(5)
↳ _[15]=x(1)+x(2)-x(3)-x(4)+x(5)
↳ _[16]=x(1)+x(2)-x(3)+x(4)-x(5)
↳ _[17]=x(1)+x(2)-x(3)+x(4)+x(5)
↳ _[18]=x(1)+x(2)+x(3)-x(4)-x(5)
↳ _[19]=x(1)+x(2)+x(3)-x(4)+x(5)
↳ _[20]=x(1)+x(2)+x(3)+x(4)-x(5)
↳ _[21]=x(1)+x(2)+x(3)+x(4)+x(5)
↳
multarr AR = multarrRestrict(A,6,"CC");  AR;
↳ _[1]=(x(2)+1/4*x(3)+1/4*x(4)+1/4*x(5))^2
↳ _[2]=(x(2)+4*x(3)-x(4)-x(5))^2
↳ _[3]=(x(2)-x(3)+4*x(4)-x(5))^2
↳ _[4]=(x(2)-x(3)-x(4)+4*x(5))^2
↳ _[5]=(x(2)-x(3)-x(4)-x(5))^2
↳ _[6]=(x(2)-x(3)-x(4)+3/2*x(5))^1
↳ _[7]=(x(2)-x(3)+3/2*x(4)-x(5))^1
↳ _[8]=(x(2)-x(3)+3/2*x(4)+3/2*x(5))^1
↳ _[9]=(x(2)-x(3)+2/3*x(4)+2/3*x(5))^1
↳ _[10]=(x(2)+3/2*x(3)-x(4)-x(5))^1
↳ _[11]=(x(2)+3/2*x(3)-x(4)+3/2*x(5))^1
↳ _[12]=(x(2)+2/3*x(3)-x(4)+2/3*x(5))^1
↳ _[13]=(x(2)+3/2*x(3)+3/2*x(4)-x(5))^1
↳ _[14]=(x(2)+2/3*x(3)+2/3*x(4)-x(5))^1
↳ _[15]=(x(2)+2/3*x(3)+2/3*x(4)+2/3*x(5))^1
↳

```

See also: [Section D.14.1.19 \[arrRestrict\]](#), page 2218; [Section D.14.1.36 \[multarrMultRestrict\]](#), page 2229; [Section D.14.1.35 \[multarrRestrict\]](#), page 2228.

D.14.1.36 multarrMultRestrict

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `multarrMultRestrict(A, k);` multiarrangement A, integer k;

Return: `[multarr]` the restricted hyperplane Multi-Arrangement (A^H_k) with multiplicities, i.e. counting with multiplicities how often one element of the restricted arrangement occurs as intersection of hyperplane of the first multiarrangement. This definition is due to Guenter M. Ziegler.

Note: A has to be non-empty.

Remarks: The restriction will only be performed, if $H_k = \ker(x_i)$ for some i. One can also restrict an arrangement with respect to any hyperplane k, but then a coordinate change is necessary first to make $H_k = \ker(x_k)$. Since such a coordinate change is not unique, please use `arrCoordchange` to do so.

Example:

```

LIB "arr.lib";
ring R = 0,(x,y,z),dp;
multarr A =ideal(x2,y2,z2,(x-y)^3,(x-z)^2,(y-z));    A;
↳ _[1]=(x)^2
↳ _[2]=(y)^2
↳ _[3]=(z)^2
↳ _[4]=(x-y)^3
↳ _[5]=(x-z)^2
↳ _[6]=(y-z)^1
↳
//The restriction of the multiarrangement is:
multarr AR = multarrMultRestrict(A,1);  AR;
↳ _[1]=(y)^5
↳ _[2]=(z)^4
↳ _[3]=(y-z)^1
↳

```

See also: [Section D.14.1.19 \[arrRestrict\]](#), page 2218; [Section D.14.1.36 \[multarrMultRestrict\]](#), page 2229; [Section D.14.1.35 \[multarrRestrict\]](#), page 2228.

D.14.1.37 arrFlats

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `size(A); A arr`

Return: `[arrposet]` Intersection lattice

Example:

```

LIB "arr.lib";
ring R = 0,(x(1..5)),dp;
arrFlats(arrBraid(5));
↳
↳
↳ === Computing poset ===
↳

```

See also: [Section D.14.1.37 \[arrFlats\]](#), page 2230.

D.14.1.38 arrLattice

Procedure from library `arr.lib` (see [Section D.14.1 \[arr_lib\]](#), page 2208).

Usage: `arrLattice(arr ARR)`

Return: `[arrposet]` intersection poset of the arrangement

Note: The algorithm works by a bottom up approach, i.e. it calculates the

Example:

```

LIB "arr.lib";
ring r;
arrLattice(arrTypeB(3));
⇒
⇒
⇒ === Computing poset ===
⇒
⇒
⇒ rank 2: found 13 flats in 0s
⇒ rank 3: found 1 flats in 0s

```

↳ _[2]=x+y
↳ _[3]=x-z
↳ _[4]=x+z
↳ _[5]=x
↳ _[6]=y-z
↳ _[7]=y+z
↳ _[8]=y
↳ _[9]=z
↳
↳ Corresponding poset:
↳ ===== rank 1: 9 flats =====
↳ (1), (2), (3), (4), (5), (6), (7), (8), (9),
↳ ===== rank 2: 13 flats =====
↳ (1,2,5,8), (1,3,6), (1,4,7), (1,9), (2,3,7), (2,4,6), (2,9), (3,4\
,5,9), (3,8), (4,8), (5,6), (5,7), (6,7,8,9),
↳ ===== rank 3: 1 flats =====
↳ (1,2,3,4,5,6,7,8,9),
↳

```

See also: [Section D.14.1.37 \[arrFlats\]](#), page 2230; [Section D.14.1.38 \[arrLattice\]](#), page 2231.

D.14.1.39 moebius

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `moebius(arrposet P)`

Return: `[arrposet]` fills in the moebius values of the flats in the poset

Example:

```

LIB "arr.lib";
ring R = 0,(x,y,z,t),dp;
arr A = arrBraid(4);
arrposet P = arrLattice(A);
↳
↳
↳ === Computing poset ===
↳
↳
↳ rank 2: found 7 flats in 0s
↳ rank 3: found 1 flats in 0s
↳
↳
↳ Matrix tests: 38
P;
↳ Given Arrangement:
↳ _[1]=x-y
↳ _[2]=x-z
↳ _[3]=x-t
↳ _[4]=y-z
↳ _[5]=y-t
↳ _[6]=z-t
↳
↳ Corresponding poset:
↳ ===== rank 1: 6 flats =====

```

```

↳ (1), (2), (3), (4), (5), (6),
↳ ===== rank 2: 7 flats =====
↳ (1,2,4), (1,3,5), (1,6), (2,3,6), (2,5), (3,4), (4,5,6),
↳ ===== rank 3: 1 flats =====
↳ (1,2,3,4,5,6),
↳ ===== rank 4: 0 flats =====
↳
↳
//As you can see the values are not calculated yet:
printMoebius(P);
↳ Moebius values:
↳ ===== rank 1: 6 flats =====
↳ (-1), (-1), (-1), (-1), (-1), (-1),
↳ ===== rank 2: 7 flats =====
↳ (0), (0), (0), (0), (0), (0), (0),
↳ ===== rank 3: 1 flats =====
↳ (0),
↳ ===== rank 4: 0 flats =====
↳
P = moebius(P);
//Now all entries are initialized:
printMoebius(P);
↳ Moebius values:
↳ ===== rank 1: 6 flats =====
↳ (-1), (-1), (-1), (-1), (-1), (-1),
↳ ===== rank 2: 7 flats =====
↳ (2), (2), (1), (2), (1), (1), (2),
↳ ===== rank 3: 1 flats =====
↳ (-6),
↳ ===== rank 4: 0 flats =====
↳

```

See also: [Section D.14.1.39 \[moebius\]](#), page 2232.

D.14.1.40 arrCharPoly

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrCharPoly(arr A)`

Return: `[intvec]` coefficients of the characteristic polynomial of `A` in increasing order

Remarks: The algorithm only returns the coefficients of the characteristic polynomial since they are whole numbers but the basering could be something different.

Example:

```

LIB "arr.lib";
ring R = 0,(x,y,z,u,v),dp;
arr A = arrBraid(5);
intvec v = arrCharPoly(A);
x*(x-1)*(x-2)*(x-3)*(x-4);
↳ x5-10x4+35x3-50x2+24x
v;
↳ 24,-50,35,-10,1

```

See also: [Section D.14.1.40 \[arrCharPoly\]](#), page 2233; [Section D.14.1.41 \[arrPoincare\]](#), page 2234.

D.14.1.41 arrPoincare

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrPoincare(A); arr A`

Return: `[intvec]` The Poincare polynomial as integer vector of the arrangement, which is equal to the second kind Poincare-Series of the Orlik-Solomon Algebra.

Example:

```
LIB "arr.lib";
ring R = 0,(x,y,z,u,v),dp;
arr A = arrBraid(5);
intvec v = arrPoincare(A);
(1+x)*(1+2x)*(1+3x)*(1+4x);
↦ 24x4+50x3+35x2+10x+1
v;
↦ 1,10,35,50,24
```

See also: [Section D.14.1.43 \[arrBoundedChambers\]](#), page 2234; [Section D.14.1.42 \[arrChambers\]](#), page 2234; [Section D.14.1.41 \[arrPoincare\]](#), page 2234.

D.14.1.42 arrChambers

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrChambers(A); arr A`

Return: `[int]` The number of chambers of an arrangement, which is equal to the evaluation of the Poincare polynomial at 1.

Example:

```
LIB "arr.lib";
ring R = 0,(x,y),dp;
arr A = ideal(x,y,x+y-1);
arrChambers(A);
↦ 7
```

See also: [Section D.14.1.43 \[arrBoundedChambers\]](#), page 2234; [Section D.14.1.42 \[arrChambers\]](#), page 2234; [Section D.14.1.41 \[arrPoincare\]](#), page 2234.

D.14.1.43 arrBoundedChambers

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `arrBoundedChambers(A); arr A`

Return: `[int]` The number of bounded chambers of an arrangement, which is equal to the evaluation of the Poincare polynomial at -1.

Example:

```
LIB "arr.lib";
ring R = 0,(x,y),dp;
arr A = ideal(x,y,x+y-1);
arrBoundedChambers(A);
↦ 1
```

See also: [Section D.14.1.43 \[arrBoundedChambers\]](#), page 2234; [Section D.14.1.42 \[arrChambers\]](#), page 2234; [Section D.14.1.41 \[arrPoincare\]](#), page 2234.

D.14.1.44 printMoebius

Procedure from library `arr.lib` (see [Section D.14.1 \[arr.lib\]](#), page 2208).

Usage: `printMoebius(A); arr A`

Return: `[]` displays the moebius values of all the flats in the poset

Remarks: Mainly used for debugging.

Example:

```
LIB "arr.lib";
ring R = 0,(x,y,z,t),dp;
arr A = arrBraid(4);
arrposet P = arrLattice(A);
↳
↳
↳ === Computing poset ===
↳
↳
↳ rank 2: found 7 flats in 0s
↳ rank 3: found 1 flats in 0s
↳
↳
↳ Matrix tests: 38
P;
↳ Given Arrangement:
↳ _[1]=x-y
↳ _[2]=x-z
↳ _[3]=x-t
↳ _[4]=y-z
↳ _[5]=y-t
↳ _[6]=z-t
↳
↳ Corresponding poset:
↳ ===== rank 1: 6 flats =====
↳ (1), (2), (3), (4), (5), (6),
↳ ===== rank 2: 7 flats =====
↳ (1,2,4), (1,3,5), (1,6), (2,3,6), (2,5), (3,4), (4,5,6),
↳ ===== rank 3: 1 flats =====
↳ (1,2,3,4,5,6),
↳ ===== rank 4: 0 flats =====
↳
↳
//As you can see the values are not calculated yet:
printMoebius(P);
↳ Moebius values:
↳ ===== rank 1: 6 flats =====
↳ (-1), (-1), (-1), (-1), (-1), (-1),
↳ ===== rank 2: 7 flats =====
↳ (0), (0), (0), (0), (0), (0), (0),
↳ ===== rank 3: 1 flats =====

↳ ===== rank 3: 1 flats =====
↳ (-6),
↳ ===== rank 4: 0 flats =====
↳

```

D.14.2 combinat_lib

Library: combinat.lib

Purpose: Some useful functions

Authors: J. Boehm, boehm @ mathematik.uni-kl.de

Overview: Some useful basic functions from combinatorics.

Procedures:

D.14.2.1 intersectLists

Procedure from library `combinat.lib` (see [Section D.14.2 \[combinat_lib\]](#), page 2236).

Usage: `intersectLists(L,M)`; L list, M list

Return: list, containing all elements of L which are elements of M

Theory: we require the elements of the lists to have a compare operator `==`.

Example:

```

LIB "combinat.lib";
intersectLists(list(1,1,2,2,3),list(2,3,3,4));
↳ [1]:
↳ 2
↳ [2]:
↳ 3
intersectLists(list(1,1,2,2,3),list(1,1,2,2,3));
↳ [1]:
↳ 1
↳ [2]:
↳ 2
↳ [3]:
↳ 3

```

D.14.2.2 sublists

Procedure from library `combinat.lib` (see [Section D.14.2 \[combinat_lib\]](#), page 2236).

Usage: `sublists(L)`; L list

Assume: L is a list

Return: list of all sublists of L.

Example:

```
LIB "combinat.lib";
list L = 1,2,3,4,5;
sublists(L);
↳ [1]:
↳   empty list
↳ [2]:
↳   [1]:
↳     1
↳ [3]:
↳   [1]:
↳     2

D.14.2.3 member

Procedure from library `combinat.lib` (see [Section D.14.2 \[combinat.lib\]](#), page 2236).

Usage: `member(e,L)`; e def, L list

Return: 1 if e is an element of L, 0 otherwise

Theory: we require the elements involved to have a compare operator `==`.

Example:

```
LIB "combinat.lib";
member(1,list(1,4,5));
⇨ 1
```

D.14.3 customstd.lib

Library: customstd.lib

Purpose: Load customstd.so

Authors: Hans Schoenemann, hannes at mathematik.uni-kl.de
Yue Ren, ren at mathematik.uni-kl.de

Overview: This library offers customly modified standard bases algorithms in order to increase the performance of other algorithms. If you require a customly modified standard bases algorithm, please contact the authors.

Procedures:

D.14.3.1 monomialabortstd

Procedure from library `customstd.lib` (see [Section D.14.3 \[customstd.lib\]](#), page 2241).

Usage: monomialabortstd(I); I ideal

Purpose: computes a standard basis and aborts if a monomial generator is found. Returns all standard basis elements that have been computed.

Note: Due to sequencing of the standard basis computation:

- If aborted, there is no guarantee that the monomial is the final standard bases element
- If ideal has a monomial generator, there is no guarantee that the computation aborts because of it

Example:

```
LIB "customstd.lib";
LIB "polylib.lib";
ring r = 0,(x,y,z,u,v),dp;
// yields normal standard basis since no monomial is found
ideal I = homog(cyclic(4),v);
monomialabortstd(I);
⇨ _[1]=x+y+z+u
⇨ _[2]=y2+2yu+u2
⇨ _[3]=yz2+z2u-yu2-u3
⇨ _[4]=yzu2+z2u2-yu3+zu3-u4-v4
⇨ _[5]=yu4+u5-yv4-uv4
⇨ _[6]=z3u2+z2u3-zv4-uv4
⇨ _[7]=z2u4+yzv4-yuv4+zuv4-2u2v4
// will not start standard basis computation in the first place,
// as one of the generators is a monomial
I = v,homog(cyclic(4),v);
monomialabortstd(I);
⇨ _[1]=v
// aborts standard basis computation when it encounters monomial u
// note that u is not the final element in the standard basis!!!
I = x+y+z,homog(cyclic(4),v);
monomialabortstd(I);
```

```

↳ _[1]=u
↳ _[2]=x+y+z+u
// aborts standard basis computation when it encounters monomial z2
// note that it is not the monomial generator x which lead to the abortion!!!
I = x,homog(cyclic(4),v);
monomialabortstd(I);
↳ _[1]=y+z+u
↳ _[2]=x+y+z+u
↳ _[3]=z2

```

D.14.3.2 satstd

Procedure from library `customstd.lib` (see [Section D.14.3 \[customstd.lib\]](#), page 2241).

Usage: `satstd(I[,J]);` I ideal, J optional ideal

Assume: J generated by variables

Purpose: computes a standard basis of I and, if possible, divides each polynomial during the computation by the variables in J. By default, J is assumed to be the ideal generated by all variables.

Note: Even if I contains a monomial generated by the variables in J, there is no guarantee that it is found during the computation. If it is found, however, 1 is immediately returned.

Note: The result is a standard basis of a partially saturated ideal wrt. the the variables in J. If the I is homogeneous and the ordering dp, the result is completely saturated wrt. to the last variable (wrt. to the first for Dp).

Example:

```

LIB "customstd.lib";
ring r = 0,(x,y,z,u,v),dp;
ideal I = x2+x,y2+y,z2+z;
// returns normal standard basis, no changes during (trivial) computation
satstd(I,ideal(u,v));
↳ _[1]=z2+z
↳ _[2]=y2+y
↳ _[3]=x2+x
// returns x+1 instead of x2+x
satstd(I,ideal(x));
↳ _[1]=x+1
↳ _[2]=z2+z
↳ _[3]=y2+y
// returns standard basis with elements of degree up to 8 (instead of 16)
deg(satstd(I^8));
↳ 8

```

D.14.4 methods_lib

Library: `methods.lib`

Purpose: installing methods in Singular

Authors: J. Boehm, boehm @ mathematik.uni-kl.de

Overview: Methods select the function to execute by the types of the input tuple. The central function is `installMethod`, which takes a hashtable associating a tuple of input types to function names and creates a corresponding procedure.

HashTables are lists with arbitrary index sets. They can be created by the command `hashTable`. Their size can be determined by the command `size`. Values can be extracted by `selectKey` or the `*` operator. HashTables can also be added using `addHashTables` or the `+` operator.

Methods can be added with the `+` operator.

Types: Method the class of all methods
 HashTable the class of all hash tables

Procedures:

D.14.5 nets_lib

Library: net.lib

Purpose: Net structures for pretty printing

Authors: J. Boehm, boehm@mathematik.uni-kl.de
 M. Mueller, mkmuelle@mathematik.uni-kl.de
 H. Rombach, rombach@mathematik.uni-kl.de
 M. Stein, maxstein77@web.de

Overview: Nets are arrays of characters, which are printed in a matrix format. They can be concatenated horizontally and vertically. When concatenating horizontally, empty rows are filled with spaces. All Singular types can be converted to a Net by applying the command `net`.

Types: Net The class of all nets

Procedures:

D.14.5.1 catNets

Procedure from library `nets.lib` (see [Section D.14.5 \[nets_lib\], page 2243](#)).

Usage: catNets(N,M); N,M Nets

Return: horizontal concatenation of N and M

Theory: The nets are concated horizontally with alignment at the top row. Can also be called with `+`.

Example:

```
LIB "nets.lib";
Net A = net("aaa");
Net B = net("b");
catNets(A,B);
↳ aaab
↳
A+B;
↳ aaab
↳
```

D.14.5.2 net

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

D.14.5.3 netBigIntMat

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

Usage: `netBigIntMat(M)`; M bigint Matrix

Assume: M is a bigintmatrix

Return: visual presentation of M

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```
LIB "nets.lib";
ring r1=101,(x,y,z),lp;
int a=111111;
int b=22222;
int c=3333;
int d=444;
bigintmat M[2][2]=a,b,c,d;
netBigIntMat(M);
↪ | 111111 22222 |
↪ | 3333   444   |
↪
```

D.14.5.4 netBigIntMatShort

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

Usage: `netBigIntMatShort(M)`; M bigint matrix

Assume: M is a bigintmatrix

Return: visual presentation of M, only the first digits of each entry

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```
LIB "nets.lib";
ring r1=101,(x,y,z),lp;
bigint a=1111111111;
bigint b=2222222222;
bigint c=3333333333;
bigint d=4444444444;
bigintmat M[2][2]=a,b,c,d;
netBigIntMatShort(M);
↪ | 1111111111 2222222222 |
↪ | 3333333333 4444444444 |
↪
```

D.14.5.5 netCoefficientRing

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

Usage: `netCoefficientRing(R)`; R ring

Assume: R is a ring

Return: visual presentation of the coefficient ring of R

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```
LIB "nets.lib";
ring r=0,x,lp;
netCoefficientRing(r);
↦ QQ
↦
```

D.14.5.6 netIdeal

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

Usage: `netIdeal(P)`; P ideal

Assume: P is a poly

Return: visual presentation of I

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```
LIB "nets.lib";
ring r;
ideal I=2x3y4,2x3y4z+x3y4z5,5x6y7z10-2x3y+4y5z8;
netIdeal(I);
↦ <2x3y4, x3y4z5+2x3y4z, 5x6y7z10+4y5z8-2x3y>
↦
```

D.14.5.7 netInt

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

Usage: `netInt(M)`; M integer

Assume: M is an integer

Return: visual presentation of M

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```
LIB "nets.lib";
ring r;
int M=5;
netInt(M);
↦ 5
↦
```

D.14.5.8 netBigInt

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

Usage: `netBigInt(M)`; M integer

Assume: M is a bigint

Return: visual presentation of M

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```
LIB "nets.lib";
ring r;
bigint M=5;
netBigInt(M);
⇒ 5
⇒
```

D.14.5.9 netIntMat

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

Usage: `netIntMat(M)`; M int matrix

Assume: M is a int matrix

Return: visual presentation of M

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```
LIB "nets.lib";
ring r1=101,(x,y,z),lp;
int a=111111;
int b=222222;
int c=333333;
int d=444444;
intmat M[2][2]=a,b,c,d;
netIntMat(M);
⇒ | 111111 222222 |
⇒ | 333333 444444 |
⇒
```

D.14.5.10 netIntMatShort

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

Usage: `netIntMatShort(M)`; M int matrix

Assume: M is a int matrix

Return: visual presentation of M, only the first digits of each entry

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```

LIB "nets.lib";
ring r1=101,(x,y,z),lp;
int a=111111;
int b=222222;
int c=333333;
int d=444444;
intmat M[2][2]=a,b,c,d;
print(M);
↳ 111111 222222
↳ 333333 444444
netIntMatShort(M);
↳ | 111111 222222 |
↳ | 333333 444444 |
↳
//
print(M);
↳ 111111 222222
↳ 333333 444444
netIntMatShort(M,2);
↳ | 11... 22... |
↳ | 33... 44... |
↳
//

```

D.14.5.11 netIntVector

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\]](#), page 2243).

Usage: `netIntVector(V)`; V int vector

Assume: V is a int vector

Return: visual presentation of V

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```

LIB "nets.lib";
ring r1=101,(x,y,z),lp;
int a=111111;
int b=222222;
int c=333333;
int d=444444;
intvec V=a,b,c,d;
netIntVector(V);
↳ | 111111 |
↳ | 222222 |
↳ | 333333 |
↳ | 444444 |
↳

```

D.14.5.12 netIntVectorShort

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\]](#), page 2243).

Usage: `netIntVectorShort(V);` V int vector

Assume: V is a int vector

Return: visual presentation of V, only the first digits of each entry

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```
LIB "nets.lib";
ring r1=101,(x,y,z),lp;
int a=111111;
int b=222222;
int c=333333;
int d=444444;
intvec V=a,b,c,d;
netIntVectorShort(V,4);
↪ | 1111... |
↪ | 2222... |
↪ | 3333... |
↪ | 4444... |
↪
```

D.14.5.13 netNumber

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

Usage: `netNumber(R);` a number

Assume: a is a number

Return: visual presentation of a

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```
LIB "nets.lib";
ring r1=101,(x,y,z),lp;
number a = 5;
netNumber(a);
↪
↪ 5
↪
```

D.14.5.14 netList

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

Usage: `netList(L);` L list

Assume: L is a list of elements

Return: visual presentation of L

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```

LIB "nets.lib";
ring r1=101,(x,y,z),lp;
list L=111, x+y, x3y-z, y+3z4;
print("list L=111, x+y, x3y-z, y+3z4");
↪ list L=111, x+y, x3y-z, y+3z4
netList(L);
↪ [111, x+y, x3y-z, y+3z4]
↪

```

D.14.5.15 netMap

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\]](#), page 2243).

Usage: `netMap(f); f map`

Assume: `f` is a map from a ring to the basering

Return: visual presentation of the map `f`

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```

LIB "nets.lib";
ring r1=101,(x,y,z),lp;
ring r2=103,(a,b,c),lp;
map f=r1,ab,ac,bc;
netMap(f);
↪ Map: r1 --> r2 , x -> ab
↪           , y -> ac
↪           , z -> bc
↪

```

D.14.5.16 netMap2

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\]](#), page 2243).

Usage: `netMap2(f); f map`

Assume: `f` is a map from a ring to the basering

Return: visual presentation of the map `f`, alternative version

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```

LIB "nets.lib";
ring r1=101,(x,y,z),lp;
ring r2=103,(a,b,c),lp;
map f=r1,ab,ac,bc;
netMap2(f);
↪ f: r1 --> r2 , x -> ab , y -> ac , z -> bc
↪

```

D.14.5.17 netmatrix

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

Usage: `netmatrix(V)`; M matrix

Assume: M is a matrix

Return: visual presentation of M

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```
LIB "nets.lib";
ring r1=101,(x,y,z),lp;
poly a=2x3y4+300xy-234z23;
poly b=2x3y4z;
poly c=x3y4z5;
poly d=5x6y7z10;
poly e=2x3y;
poly f=4y5z8;
matrix M[2][3]=a,b,c,d,e,f;
print(M);
  ↳ 2x3y4-3xy-32z23, 2x3y4z, x3y4z5,
  ↳ 5x6y7z10,          2x3y,  4y5z8
netmatrix(M);
  ↳ | 2x3y4-3xy-32z23 2x3y4z x3y4z5 |
  ↳ | 5x6y7z10      2x3y  4y5z8 |
  ↳
```

D.14.5.18 netmatrixShort

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

Usage: `netmatrixShort(M)`; M matrix

Assume: M is a matrix

Return: visual presentation of M

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```
LIB "nets.lib";
ring r1=101,(x,y,z),lp;
poly a=2x3y4+300xy-234z23;
poly b=2x3y4z;
poly c=x3y4z5;
poly d=5x6y7z10;
poly e=2x3y-2x3y4+300xy-234z23;
poly f=4y5z8;
matrix M[2][3]=a,b,c,d,e,f;
netmatrixShort(M, 10);
  ↳ | 2x3y4-3xy-32z23 2x3y4z          x3y4z5 |
  ↳ | 5x6y7z10      -2x3y4+2x3y-3xy-32z23 4y5z8 |
  ↳
```

D.14.5.19 netPoly

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\]](#), page 2243).

Usage: `netPoly(P);` P poly

Assume: P is a poly

Return: visual presentation of P over two rows

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```
LIB "nets.lib";
// from 3.3.1 Examples of ring declarations
//
ring R1 = 32003,(x,y,z),dp;
poly q6=1;
print(q6);
↳ 1
netPoly(q6);
↳
↳ 1
↳
poly q7=-1;
print(q7);
↳ -1
netPoly(q7);
↳
↳ -1
↳
poly q8=2;
print(q8);
↳ 2
netPoly(q8);
↳
↳ 2
↳
poly q9=-2;
print(q9);
↳ -2
netPoly(q9);
↳
↳ -2
↳
poly q1=x+y+z;
print(q1);
↳ x+y+z
netPoly(q1);
↳
↳ x+y+z
↳
poly q2=xy+xz+yz;
print(q2);
```

```

↳ xy+xz+yz
netPoly(q2);
↳
↳ xy+xz+yz
↳
poly q3=2x3y3z4-3x4y5z6;
print(q3);
↳ -3x4y5z6+2x3y3z4
netPoly(q3);
↳ 4 5 6 3 3 4
↳ -3x y z +2x y z
↳
poly q4=x3y3z4-x4y5z6;
print(q4);
↳ -x4y5z6+x3y3z4
netPoly(q4);
↳ 4 5 6 3 3 4
↳ -x y z +x y z
↳
poly q5=-x3y3z4+x4y5z6;
print(q5);
↳ x4y5z6-x3y3z4
netPoly(q5);
↳ 4 5 6 3 3 4
↳ x y z -x y z
↳
ring R2 = 32003,(x(1..10)),dp;
poly w6=1;
print(w6);
↳ 1
netPoly(w6);
↳
↳ 1
↳
poly w7=-1;
print(w7);
↳ -1
netPoly(w7);
↳
↳ -1
↳
poly w2=-x(1)-(2)-x(3);
print(w2);
↳ -x(1)-x(3)-2
netPoly(w2);
↳
↳ -x(1)-x(3)-2
↳
poly w3=x(1)*x(2)+x(1)*x(2)+x(2)*x(3);
print(w3);
↳ 2*x(1)*x(2)+x(2)*x(3)
netPoly(w3);
↳

```

```

↳ 2x(1)x(2)+x(2)x(3)
↳
poly w4=x(1)*x(2)-x(1)*x(2)-x(2)*x(3);
print(w4);

D.14.5.20 netPrimePower

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

Usage: `netPrimePower(n,m);` n,m int

Return: visual presentation of the prime power n^m

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```

LIB "nets.lib";
ring r=0,x,lp;
int n=2;
int m=5;
netPrimePower(n,m);
 $\mapsto 2^5$ 
 $\mapsto$ 

```

D.14.5.21 netRing

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\], page 2243](#)).

Usage: `netRing(f);` f ring

Assume: R is a ring

Return: visual presentation of R

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```

LIB "nets.lib";
// from 3.3.1 Examples of ring declarations
ring r1 = 32003,(x,y,z),dp;
netRing(r1);
⇨ FF_32003[x,y,z]

D.14.5.22 netString

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\]](#), page 2243).

Usage: `netString(M)`; M string

Assume: M is a string

Return: visual presentation of M

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```
LIB "nets.lib";
string M="Hallo";
netString(M);
↦ Hallo
↦
```

D.14.5.23 netvector

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\]](#), page 2243).

Usage: netvector(V); V vector

Assume: V is a vector

Return: visual presentation of V

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```
LIB "nets.lib";
ring r1=101,(x,y,z),lp;
poly a=2x3y4;
poly b=2x3y4z;
poly c=x3y4z5;
poly d=5x6y7z10;
poly e=2x3y;
poly f=4y5z8;
vector V=[a,b,c,d,e,f];
netvector(V);
↦ | 2x3y4      |
↦ | 2x3y4z     |
↦ | x3y4z5     |
↦ | 5x6y7z10   |
↦ | 2x3y       |
↦ | 4y5z8      |
↦
```

D.14.5.24 netvectorShort

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\]](#), page 2243).

Usage: netvectorShort(V); V vector

Assume: V is a vector

Return: visual presentation of V, short version

Theory: A Singular object is converted into a character array (a Net) for on screen printing.

Example:

```

LIB "nets.lib";
ring r1=101,(x,y,z),lp;
poly a=2x3y4;
poly b=2x3y4z-5x6y7z10;
poly c=x3y4z5;
poly d=5x6y7z10;
poly e=2x3y;
poly f=4y5z8+5x6y7z10;
vector V=[a,b,c,d,e,f];
netvectorShort(V);
⇒ | 2x3y4          |
⇒ | -5x6y7z10+2x3y4z |
⇒ | x3y4z5         |
⇒ | 5x6y7z10       |
⇒ | 2x3y           |
⇒ | 5x6y7z10+4y5z8  |
⇒

```

D.14.5.25 stackNets

Procedure from library `nets.lib` (see [Section D.14.5 \[nets.lib\]](#), page 2243).

Usage: `stackNets(N,M)`; N,M Nets

Return: vertical concatenation of N and M

Theory: The nets are concated vertically with alignment at the left column.

Example:

```

LIB "nets.lib";
Net A = net("aaa");
Net B = net("b");
stackNets(A,B);
⇒ aaa
⇒ b
⇒
A+B;
⇒ aaab
⇒

```

D.14.6 phindex.lib

Library : `phindex.lib`

Purpose: Procedures to compute the index of real analytic vector fields

Author: Victor Castellanos

Note: To compute the Poincare-Hopf index of a real analytic vector field with an algebraically isolated singularity at 0 (w. an a. i. s), we use the algebraic formula for the degree of the real analytic map germ found by Eisenbud-Levine in 1997. This result was also proved by Khimshiashvili. If the isolated singularity is non algebraically isolated and the vector field has similar reduced complex zeroes of codimension 1, we use a formula as the Eisenbud-Levine found by Victor Castellanos, in both cases is necessary to use a local order (ds,...). To compute the signature of a quadratic form (or symmetric matrix) we use the method of Lagrange.

Procedures:**D.14.6.1 signatureL**

Procedure from library `phindex.lib` (see [Section D.14.6 \[phindex.lib\]](#), page 2259).

Usage: `signatureL(M[,r]);` M symmetric matrix, r int (optional).

Return: the signature of M of type int or if r is given and $!=0$ then intvec with (signature, nr. of +, nr. of -) is returned.

Theory: Given the matrix M , we construct the quadratic form associated. Afterwards we use the method of Lagrange to compute the signature. The law of inertia for a real quadratic form $A(x,x)$ says that in a representation of $A(x,x)$ as a sum of independent squares $A(x,x)=\sum_{i=1}^r a_i X_i^2$.

The number of positive and the number of negative squares are independent of the choice of representation. The signature $-s-$ of $A(x,x)$ is the difference between the number $-pi-$ of positive squares and the number $-nu-$ of negative squares in the representation of $A(x,x)$. The rank $-r-$ of M (or $A(x,x)$) and the signature $-s-$ determine the numbers $-pi-$ and $-nu-$ uniquely, since

$$r=pi+nu, \quad s=pi-nu.$$

The method of Lagrange is a procedure to reduce any real quadratic form to a sum of squares.

Ref. Gantmacher, The theory of matrices, Vol. I, Chelsea Publishing Company, NY 1960, page 299.

Example:

```
LIB "phindex.lib";
ring r=0,(x),ds;
matrix M[5][5]=0,0,0,1,0,0,1,0,0,-1,0,0,1,0,0,1,0,0,3,0,0,-1,0,0,1;
signatureL(M,1); //The rank of M is 3+1=4
↳ 2,3,1
matrix H[5][5]=0,-7,0,1,0,-7,1,0,0,-1,0,0,1,0,0,1,0,0,-3,5,0,-1,0,5,1;
signatureL(H);
↳ 1
```

D.14.6.2 signatureLqf

Procedure from library `phindex.lib` (see [Section D.14.6 \[phindex.lib\]](#), page 2259).

Usage: `signatureLqf(h);` h quadratic form (poly type).

Return: the signature of h of type int or if r is given and $!=0$ then intvec with (signature, nr. of +, nr. of -) is returned.

Theory: To compute the signature we use the method of Lagrange. The law of inertia for a real quadratic form $h(x,x)$ says that in a representation of $h(x,x)$ as a sum of independent squares $h(x,x)=\sum_{i=1}^r a_i X_i^2$ the number of positive and the number of negative squares are independent of the choice of representation. The signature $-s-$ of $h(x,x)$ is the difference between the number $-pi-$ of positive squares and the number $-nu-$ of negative squares in the representation of $h(x,x)$. The rank $-r-$ of $h(x,x)$ and the signature $-s-$ determine the numbers $-pi-$ and $-nu-$ uniquely, since

$$r=pi+nu, \quad s=pi-nu.$$

The method of Lagrange is a procedure to reduce any real quadratic form to a sum of squares.

Ref. Gantmacher, The theory of matrices, Vol. I, Chelsea Publishing Company, NY 1960, page 299.

Example:

```
LIB "phindex.lib";
ring r=0,(x(1..4)),ds;
poly Ax=4*x(1)^2+x(2)^2+x(3)^2+x(4)^2-4*x(1)*x(2)-4*x(1)*x(3)+4*x(1)*x(4)+4*x(2)*x(3);
signatureLqf(Ax,1); //The rank of Ax is 3+1=4
  ↦ 2,3,1
poly Bx=2*x(1)*x(4)+x(2)^2+x(3)^2;
signatureLqf(Bx);
  ↦ 2
```

D.14.6.3 PH_ais

Procedure from library `phindex.lib` (see [Section D.14.6 \[phindex.lib\]](#), page 2259).

Usage: PH_ais(I); I ideal of coordinates of the vector field.

Return: the Poincare-Hopf index of type int.

Note: the isolated singularity must be algebraically isolated.

Theory: The Poincare-Hopf index of a real vector field X at the isolated singularity 0 is the degree of the map $(X/|X|) : S_{\epsilon} \rightarrow S$, where S is the unit sphere, and the spheres are oriented as $(n-1)$ -spheres in \mathbb{R}^n . The degree depends only on the germ, X , of X at 0 . If the vector field X is real analytic, then an invariant of the germ is its local ring

$$Q_X = R[[x_1, \dots, x_n]]/I_X$$

where $R[[x_1, \dots, x_n]]$ is the ring of germs at 0 of real-valued analytic functions on \mathbb{R}^n , and I_X is the ideal generated by the components of X . The isolated singularity of X is algebraically isolated if the algebra Q_X is finite dimensional as real vector space, geometrically this means that 0 is also an isolated singularity for the complexified vector field. In this case the Poincare-Hopf index is the signature of the non degenerate bilinear form \langle, \rangle obtained by composition of the product in the algebra Q_X with a linear functional map

$$\langle, \rangle : (Q_X) \times (Q_X) \rightarrow Q_X \xrightarrow{L} \mathbb{R}$$

with $L(J_0) > 0$, where J_0 is the residue class of the Jacobian determinant in Q_X . Here, we use a natural linear functional defined as follows. Suppose that $E = \{E_1, \dots, E_r\}$ is a basis of Q_X , then J_0 can be written as

$$J_0 = a_1 E_{j_1} + \dots + a_k E_{j_k}, \quad j_s \in \{1, \dots, r\}, \quad s = 1, \dots, k, \quad k \leq r, \quad \text{where } a_s \text{ are constant.}$$

The linear functional $L: Q_X \rightarrow \mathbb{R}$ is defined as $L(E_{j_1}) = (a_1)/|a_1| = \text{sign of } a_1$,

the other elements of the base are sent to 0.

Refs. -Eisenbud & Levine, An algebraic formula for the degree of a C^∞ map germ, Ann. Math., 106, (1977), 19-38.

-Khimshiashvili, On a local degree of a smooth map, Trudi Tbilisi Math. Inst., (1980), 105-124.

Example:

```
LIB "phindex.lib";
ring r=0,(x,y,z),ds;
ideal I=x^3-3xy^2,-y^3+3yx^2,z^3;
PH_ais(I);
  ↦ 3
```

D.14.6.4 PH_nais

Procedure from library `phindex.lib` (see [Section D.14.6 \[phindex.lib\]](#), page 2259).

Usage: `PH_nais(I)`; I ideal of coordinates of the vector field.

Return: the Poincare-Hopf index of type `int`.

Note: the vector field must be a non algebraically isolated singularity at 0, with reduced complex zeros of codimension 1.

Theory: Suppose that 0 is an algebraically isolated singularity of the real analytic vector field X , geometrically this corresponds to the fact that the complexified vector field has positive dimension singular locus, algebraically this mean that the local ring $Q_x = R[[x_1..x_n]]/I_x$ where $R[[x_1..x_n]]$ is the ring of germs at 0 of real-valued analytic functions on \mathbb{R}^n , and I_x is the ideal generated by the components of X is infinite dimensional as real vector space. In the case that X has a reduced hypersurface as complex zeros we have the next. There exist a real analytic function $f: \mathbb{R}^n \rightarrow \mathbb{R}$, and a real analytic vector field Y s. t. $X = fY$. The function f does not change of sign out of 0 and

$$M_x = R[[x_1..x_n]]/(I_x : \text{radical}(I_x))$$

is a finite dimensional sub-algebra of Q_x . The Poincare-Hopf index of X at 0 is the sign of f times the signature of the non degenerate bilinear form \langle, \rangle obtained by composition of the product in the algebra M_x with a linear functional map

$$\langle, \rangle : (M_x)_x(M_x) \xrightarrow{(\cdot)} M_x \xrightarrow{(L)} \mathbb{R}$$

with $L(J_p) > 0$, where J_p is the residue class of the Jacobian determinant of X , JX , over f^n , $JX/(f^n)$ in M_x . Here, we use a natural linear functional defined as follows. Suppose that $E = \{E_1, \dots, E_r\}$ is a basis of M_x , then J_p is writing as $J_p = a_1 E_{j_1} + \dots + a_k E_{j_k}$, $j_s \in \{1 \dots r\}$, $s = 1..k$, $k \leq r$, where a_s are constant. The linear functional $L: M \rightarrow \mathbb{R}$ is defined as $L(E_{j_1}) = (a_1)/|a_1| = \text{sign of } a_1$, the other elements of the base are sent to 0.

D.14.7 polybori.lib

Library: `polybori.lib`

Purpose: A Singular Library Interface for PolyBoRi

Authors: Maximilian Kammermeier: Max0791@gmx.de
Susanne Scherer: sscherer90@yahoo.de

Overview: A library for using PolyBoRi in the SINGULAR interface, with procedures that convert structures (polynomials, rings, ideals) in both directions. Therefore, it is possible to

compute boolean groebner basis via [Section D.14.7.1 \[boolean_std\]](#), page 2263. Polynomials can be converted to zero-suppressed decision diagrams (zdd) and vice versa.

For usability it defines the PolyBoRi types `bideal`, `bpoly`, and `bring` which are equivalent to Singular's `ideal`, `poly`, and `ring`, as well as `bset` which corresponds to the type `zdd` introduced here. In addition `bvar(i)` constructs the Boolean variable corresponding to `var(i)` from current `ring`;

For convenience, the corresponding types can be converted explicitly or implicitly while assigning. Also several SINGULAR operators were overloaded: `bring` comes with `nvars`, `bpoly` implements `lead`, `leadmonom` and `leadcoef`. Objects of this type may be added and multiplied, too. Finally, `bideal` yields `std` and `size` as well as addition and element access.

Hence, by using these types PolyBoRi functionality can be carried out seamlessly in SINGULAR:

```
> LIB "polybori.lib";
> ring r0=2,x(1..4),lp;
> def x=bvar; // enforce Boolean variables

> bpoly f1=x(1)+x(4);
> bpoly f2=x(1)+x(3)*x(1);
> bideal bI=list(f1,f2);

> std(bI);
_[1] = x(1) + x(4)
_[2] = x(3)*x(4) + x(4)
```

Note: For using this library SINGULAR's `python` interface must be available on your system. Please `./configure --with-python` when building SINGULAR for this purpose.

There are prebuilt binary packages for PolyBoRi available from <http://polybori.sf.net/>.

For building your own PolyBoRi please ensure that you have `scons` and a development version of the boost libraries installed on you system. Then you may execute the following commands in a `bash`-style shell to build PolyBoRi available to `python`:

```
PBDIR=/path/to/custom/polybori
wget http://downloads.sf.net/project/polybori/polybori/\
0.8.2/polybori-0.8.2.tar.gz
tar -xvzf polybori-0.8.2.tar.gz
cd polybori-0.8.2
scons install PREFIX=$PBDIR PYINSTALLPREFIX=$PBDIR/python
export PYTHONPATH=$PBDIR/python:$PYTHONPATH
```

References:

See <http://polybori.sf.net> for details about PolyBoRi.

Procedures: See also: [Section 3.8 \[Libraries\]](#), page 55; [Section 4.24 \[User defined types\]](#), page 136; [Section 4.28 \[pyobject\]](#), page 140.

D.14.7.1 boolean_std

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori_lib\]](#), page 2262).

Usage: `boolean_std(Is);` Is ideal

Return: Singular ideal of the boolean groebner basis of Is

Example:

```
LIB "polybori.lib";
ring r0=2,x(1..4),lp;
poly f1=x(1)^2+2*x(2)*(x(3))-x(4)^3;
poly f2=x(1)^2-x(3)*x(1);
poly f3=x(2)+5-2*x(1);
poly f4=x(1)*x(2)-x(3);
ideal I=f1,f2,f3,f4;
boolean_std(I);           // implicitly add x(i)^2-x(i)
bideal bI=I;              // alternative syntax
bideal re = std(bI);      // Continue PolyBoRi computations
std(re[1..2]);
ring r1=0,x,Dp;
poly f1=x3+2*x+1;
poly f2=x10-x5+2x;
poly f3=19;
ideal I=f1,f2,f3;
boolean_std(I);
ring r2=32003,(x,y,z),Dp;
poly f1=xz+y+20*x^2*y;
poly f2=32002*xy+xz2+y;
ideal I=f1,f2;
boolean_std(I);
ring r2=32003,(x,y,z),Dp;
poly f1=xyz+20*x^2*y-3*xz+15;
poly f2=32002*xy+z2;
poly f3=19*x5y;
ideal I=f1,f2,f3;
boolean_std(I);
```

See also: [Section D.14.7.7 \[boolean_ideal\]](#), page 2266; [Section D.14.7.4 \[boolean_poly\]](#), page 2265; [Section D.14.7.2 \[boolean_poly_ring\]](#), page 2264; [Section D.14.7.13 \[from_boolean_ideal\]](#), page 2269; [Section D.14.7.10 \[from_boolean_poly\]](#), page 2267.

D.14.7.2 boolean_poly_ring

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori.lib\]](#), page 2262).

D.14.7.3 boolean_constant

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori.lib\]](#), page 2262).

Usage: `boolean_constant(const[, rb]);` const constant and rb boolean ring

Return: default: constant const in the representation of the boolean ring
 rb==boolean_poly_ring(basering); optional input: rb=boolean ring rb

Example:

```
LIB "polybori.lib";
ring r=7,(x,y),Dp;
pyobject rb=boolean_poly_ring(r);
boolean_constant(int(3));
```

```

typeof(boolean_constant(int(3)));
boolean_constant(int(0));
typeof(boolean_constant(int(0)));

```

See also: [Section D.14.7.7 \[boolean_ideal\]](#), page 2266; [Section D.14.7.1 \[boolean_std\]](#), page 2263.

D.14.7.4 boolean_poly

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori.lib\]](#), page 2262).

Usage: `boolean_poly(ps[, dir, rb]);` ps polynomial, dir integer zero or one, rb boolean ring

Return: default: polynomial ps in the representation of the boolean ring
`rb==boolean_poly_ring(basering);` optional input: boolean ring rb

Note: via the optional input dir, one can choose the computation method (either direct[`dir==0`] or recursive[`dir==1`]). default: recursive

Example:

```

LIB "polybori.lib";
ring r=0,x(1..5),Dp;
poly f=x(2)*(x(3)-x(1))+x(4)*x(5);
bring rb=r;
boolean_poly(f);
boolean_poly(f,0);
boolean_poly(f,0,boolean_poly_ring(r));
boolean_poly(f,0,rb);
poly g=0;
boolean_poly(g);
poly g=1;
boolean_poly(g);

```

See also: [Section D.14.7.7 \[boolean_ideal\]](#), page 2266; [Section D.14.7.1 \[boolean_std\]](#), page 2263.

D.14.7.5 direct_boolean_poly

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori.lib\]](#), page 2262).

Usage: `boolean_poly(ps[, rb]);` ps polynomial, rb boolean ring

Return: default: polynomial ps in the representation of the boolean ring
`rb==boolean_poly_ring(basering);` optional input: boolean ring rb

Example:

```

LIB "polybori.lib";
ring r0=2,x(1..4),lp;
bring rb=r0;
poly f=x(1)^2+2*x(2)*(x(3))-x(4)^3;
direct_boolean_poly(f);
direct_boolean_poly(f,rb);
ring r1=0,x,Dp;
poly f=x^3+2x+1;
direct_boolean_poly(f);
ring r2=32003,(x,y,z),Dp;
poly f=xyz+20*x^2*y-3*xz+15;
direct_boolean_poly(f);

```

See also: [Section D.14.7.7 \[boolean_ideal\]](#), page 2266; [Section D.14.7.1 \[boolean_std\]](#), page 2263.

D.14.7.6 recursive_boolean_poly

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori.lib\]](#), page 2262).

Usage: `boolean_poly(ps[, rb]);` ps polynomial, rb boolean ring

Return: default: polynomial ps in the representation of the boolean ring
`rb==boolean_poly_ring(basering);` optional input: rb boolean ring

Example:

```
LIB "polybori.lib";
ring r0=2,x(1..4),lp;
poly f=x(1)^2+2*x(2)*(x(3))-x(4)^3;
recursive_boolean_poly(f);
ring r1=0,x,Dp;
poly f=x3+2x+1;
recursive_boolean_poly(f);
ring r2=32003,(x,y,z),Dp;
def br2=boolean_poly_ring(r2);
bring bbr2=r2;
poly f=xyz+20*x^2*y-3*xz+15;
recursive_boolean_poly(f,br2);
recursive_boolean_poly(f,bbr2);
```

See also: [Section D.14.7.7 \[boolean_ideal\]](#), page 2266; [Section D.14.7.1 \[boolean_std\]](#), page 2263.

D.14.7.7 boolean_ideal

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori.lib\]](#), page 2262).

Usage: `boolean_ideal(Is[, rb]);` Is Ideal, rb boolean ring

Return: default: ideal Is in the representation of the boolean ring
`rb==boolean_poly_ring(basering);` optional input: rb boolean ring

Example:

```
LIB "polybori.lib";
ring r0=2,x(1..4),lp;
poly f1=x(1)^2+2*x(2)*(x(3))-x(4)^3;
poly f2=x(1)^2-x(3)*x(1);
poly f3=x(2)+5-2*x(1);
poly f4=x(1)*x(2)-x(3);
ideal I=f1,f2,f3,f4;
boolean_ideal(I);
ring r1=0,x,Dp;
poly f1=x3+2*x+1;
poly f2=x10-x5+2x;
poly f3=19;
ideal I=f1,f2,f3;
boolean_ideal(I);
ring r2=32003,(x,y,z),Dp;
bring bbr2=r2;
poly f1=xyz+20*x^2*y-3*xz+15;
poly f2=32002*xy+z2;
poly f3=19;
ideal I=f1,f2,f3;
```

```
boolean_ideal(I);
boolean_ideal(I,bbr2);
```

See also: [Section D.14.7.1 \[boolean_std\]](#), page 2263.

D.14.7.8 boolean_set

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori_lib\]](#), page 2262).

Usage: `boolean_set(ss[, rb]);` ss zdd, rb boolean ring

Return: default: boolean set ss in the representation of a Polybori boolean set in the ring
rb==boolean_poly_ring(basing); optional input: boolean ring rb

Example:

```
LIB "polybori.lib";
ring rs=0,(x,y,z),Dp;
poly ps=(x+1)*(y+1)*(z+1);
zdd fz=ps;
boolean_set(fz);
poly g=x*y*z+1;
zdd gz=g;
boolean_set(gz);
ring R=0,(x(1..4)),Dp;
def Rb=boolean_poly_ring(R);
poly h=(x(1)+1)*(x(2)+1)*(x(3)+1)*(x(4)+1);
zdd hz=h;
boolean_set(hz);
```

See also: [Section D.14.7.7 \[boolean_ideal\]](#), page 2266; [Section D.14.7.1 \[boolean_std\]](#), page 2263.

D.14.7.9 from_boolean_constant

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori_lib\]](#), page 2262).

Usage: `from_boolean_constant(pb);` pb pyobject

Return: constant polynomial

Example:

```
LIB "polybori.lib";
ring rs=0,(x,y,z),Dp;
def rsb=boolean_poly_ring(rs);
poly f=(x+y)*x+z;
bpoly pp=f;
from_boolean_constant(0);
from_boolean_constant(1);
from_boolean_constant(pp);
```

See also: [Section D.14.7.7 \[boolean_ideal\]](#), page 2266; [Section D.14.7.1 \[boolean_std\]](#), page 2263.

D.14.7.10 from_boolean_poly

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori_lib\]](#), page 2262).

Usage: `from_boolean_poly(ps[, dir]);` ps polynomial, dir integer zero or one

Return: default: polynomial ps in the representation of the boolean ring

Note: via the optional input `dir`, one can choose the computation method (either `direct[dir==0]` or `recursive[dir==1]`). default: `direct`

Example:

```
LIB "polybori.lib";
ring r=0,(x,y,z),Dp;
def rb=boolean_poly_ring(r);
poly f=x^2+2*y+5*z^4;
bpoly pp=f;
from_boolean_poly(pp);
from_boolean_poly(pp,1);
ring r2=5,(x,y,z),Dp;
def rb2=boolean_poly_ring(r2);
poly f2=x+y+z;
bpoly pp2=f2;
from_boolean_poly(pp);
from_boolean_poly(pp,1);
```

See also: [Section D.14.7.7 \[boolean_ideal\]](#), page 2266; [Section D.14.7.1 \[boolean_std\]](#), page 2263.

D.14.7.11 `direct_from_boolean_poly`

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori.lib\]](#), page 2262).

Usage: `from_boolean_poly(pb)`; `pb` boolean polynomial

Return: polynomial in Singular

Example:

```
LIB "polybori.lib";
ring r=0,(x,y,z),Dp;
pyobject rb=boolean_poly_ring(r);
poly f=x^2+2*y^3+3*z^3;
bpoly pp=f;
direct_from_boolean_poly(pp);
poly g=0;
bpoly pp=g;
direct_from_boolean_poly(pp);
```

See also: [Section D.14.7.7 \[boolean_ideal\]](#), page 2266; [Section D.14.7.4 \[boolean_poly\]](#), page 2265; [Section D.14.7.2 \[boolean_poly_ring\]](#), page 2264; [Section D.14.7.1 \[boolean_std\]](#), page 2263; [Section D.14.7.13 \[from_boolean_ideal\]](#), page 2269.

D.14.7.12 `recursive_from_boolean_poly`

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori.lib\]](#), page 2262).

Usage: `recursive_from_boolean_poly(pb)`; `pb` boolean polynomial

Return: polynomial in Singular

Example:

```
LIB "polybori.lib";
ring rs=0,(x,y,z),Dp;
def rsb=boolean_poly_ring(rs);
poly f=(x+y)*x+z;
bpoly pp=f;
```

```

recursive_from_boolean_poly(pp);
ring rs2=2,(x,y,z),Dp;
def rsb2=boolean_poly_ring(rs2);
poly f2=(x+y)*x+x;
bpoly pp2=f2;
recursive_from_boolean_poly(pp);

```

See also: [Section D.14.7.7 \[boolean_ideal\]](#), page 2266; [Section D.14.7.4 \[boolean_poly\]](#), page 2265; [Section D.14.7.2 \[boolean_poly_ring\]](#), page 2264; [Section D.14.7.13 \[from_boolean_ideal\]](#), page 2269; [Section D.14.7.10 \[from_boolean_poly\]](#), page 2267.

D.14.7.13 from_boolean_ideal

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori.lib\]](#), page 2262).

Usage: `from_boolean_ideal(I);` I boolean ideal

Return: ideal in Singular

Example:

```

LIB "polybori.lib";
ring rs=0,(x,y,z),Dp;
def rb3=boolean_poly_ring(rs);
poly f1=x+y;
poly f2=x+z;
bpoly pp =f1;
bpoly p = f2;
bideal Ib;
list K=(p,pp);
Ib=K;
from_boolean_ideal(Ib);
ring rs2=5,(x,y,z),Dp;
def rb4=boolean_poly_ring(rs2);
poly p1=x+y;
poly p2=x+z;
poly p3=y+z;
bpoly p = p1;
bpoly pp = p2;
bpoly ppp = p3;
bideal Ib;
list K=(p,pp,ppp);
Ib=K;
from_boolean_ideal(Ib);

```

See also: [Section D.14.7.7 \[boolean_ideal\]](#), page 2266; [Section D.14.7.4 \[boolean_poly\]](#), page 2265; [Section D.14.7.2 \[boolean_poly_ring\]](#), page 2264; [Section D.14.7.1 \[boolean_std\]](#), page 2263; [Section D.14.7.10 \[from_boolean_poly\]](#), page 2267.

D.14.7.14 from_boolean_set

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori.lib\]](#), page 2262).

Usage: `from_boolean_set(sb);` sb boolean set

Return: Boolean set sb in the representation of a zdd

Example:

```

LIB "polybori.lib";
ring r=0,(x,y,z),Dp;
poly f=(x+1)*(y+1)*(z+1);
bpoly fb=f;
bset fs=fb;
from_boolean_set(fs);
poly g=x*y*z+1;
bpoly gb=g;
bset gs=gb;
from_boolean_set(gs);
ring R=0,(x(1..4)),Dp;
poly h=(x(1)+1)*(x(2)+1)*(x(3)+1)*(x(4)+1);
pyobject hb=boolean_poly(h);
def hs=hb.set();
from_boolean_set(hs);

```

See also: [Section D.14.7.7 \[boolean_ideal\]](#), page 2266; [Section D.14.7.1 \[boolean_std\]](#), page 2263.

D.14.7.15 bvar

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori.lib\]](#), page 2262).

Usage: `bvar(i); int i`

Return: `i`-th variable of Boolean ring corresponding to current basering

Example:

```

LIB "polybori.lib";
ring r = 2,(x,y,z),Dp;
bvar(1); // -> x

```

See also: [Section D.14.7.2 \[boolean_poly_ring\]](#), page 2264; [Section 5.1.165 \[var\]](#), page 285.

D.14.7.16 poly2zdd

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori.lib\]](#), page 2262).

Usage: `poly2zdd(poly ps); polynomial ps`

Return: polynomial `ps` in zdd representation

Example:

```

LIB "polybori.lib";
ring r=0,x(1..5),Dp;
poly f=(x(1)+1)*(x(2)+1)*(x(3)+1)*x(4)*x(5);
poly2zdd(f);
poly g=x(3);
poly2zdd(g);

```

See also: [Section D.14.7.4 \[boolean_poly\]](#), page 2265; [Section D.14.7.14 \[from_boolean_set\]](#), page 2269.

D.14.7.17 zdd2poly

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori.lib\]](#), page 2262).

Usage: `zdd2poly(ss); zero-supressed decision diagram ss`

Return: zdd `ss` in polynomial representation

Example:

```

LIB "polybori.lib";
ring r=0,x(1..5),Dp;
poly f=(x(1)+1)*(x(2)+1)*(x(3)+1)*x(4)*x(5);
zdd2poly(poly2zdd(f));
poly g=x(3);
zdd2poly(poly2zdd(g));
poly g=0;
zdd2poly(poly2zdd(0));
poly g=1;
zdd2poly(poly2zdd(01));

```

See also: [Section D.14.7.8 \[boolean_set\]](#), page 2267; [Section D.14.7.10 \[from_boolean_poly\]](#), page 2267.

D.14.7.18 disp_zdd

Procedure from library `polybori.lib` (see [Section D.14.7 \[polybori.lib\]](#), page 2262).

Usage: `disp_zdd(ss)`; zero-suppressed decision diagram `ss`

Return: string containing visualization of `ss`

Note: the resulting string is the visualization of the polynomial that corresponds to `ss`, but with a additional structure that comes from the `zdd`. Every reached else- Branch induces a new line in the string.

Example:

```

LIB "polybori.lib";
ring r1=0,(x,y,z),Dp;
poly f1=xyz+xy+xz+yz+y+z+x+1;
zdd s1=f1;
disp_zdd(s1);
ring r2=0,x(1..6),Dp;
poly f2=x(1)+x(2)+x(3)+x(5)^2+x(6);
zdd s2=f2;
disp_zdd(s2);
ring r4=0,x(1..6),Dp;
poly f2=x(1)+1;
zdd s2=f2;
disp_zdd(s2);
ring r2=0,x(1..6),Dp;
poly f2=x(1)*x(2)*(x(3)-x(5)^2*x(6))+3*x(4)*x(5)-3;
zdd s2=f2;
disp_zdd(s2);
poly f4=0;
zdd s4=f4;
disp_zdd(s4);
poly f5=1;
zdd s5=f5;
disp_zdd(s5);

```

See also: [Section D.14.7.16 \[poly2zdd\]](#), page 2270; [Section D.14.7.17 \[zdd2poly\]](#), page 2270.

D.14.8 sets_lib

Library: sets.lib

Purpose: Sets in Singular

Authors: J. Boehm, boehm @ mathematik.uni-kl.de
 D. Wienholz, wienholz @ mathematik.uni-kl.de
 S. Zillien, zillien @ rhrk.uni-kl.de

Overview: We implement the new class set and all basic methods needed to work with sets. A set is generated from a list. After the generating of a set, the adding of an element or the union of two sets, automatically every double element is removed to secure that no element occurs in a set more than once.

There is a comparison operator, we access the operator via the function isEqual. This function isEqual can be used to compare two elements of the same type (Set, list, int, bigint, string, intmat, bigintmat, intvec, ring, map, poly, matrix, ideal, module, vector, resolution) and also works for comparing of int, bigint and number with each other, similarly for matrix, bigintmat and intmat.

The function size can be used to determine the number of elements.

The + operator is used for the union, the * operator for the intersection.

The operators < and > can be used for inclusion tests.

The print function can be used for printing sets.

Note that the implementation of the underlying data structure and algorithms is very trivial and will at some point be replaced with something more efficient.

Types: Set The class of all sets

Procedures:

D.14.8.1 set

Procedure from library `sets.lib` (see [Section D.14.8 \[sets.lib\]](#), page 2272).

Usage: set(l) or *=l (short form of * = set(l)); l list

Return: Set, the set created from the entered list

Example:

```
LIB "sets.lib";
//example for set
Set S0a = list(list(1,2,3),list(list(1,2)),list(10,11));
Set S0b = list(list(10,11),list(list(1,2)));
S0b<S0a;
⇒ 1
S0a<S0b;
⇒ 0
S0a==S0a;
⇒ 1
S0a==S0b;
⇒ 0
list L = 1,1,2,3;
Set S1 = L;
S1;
```

```

⇒ {3; 2; 1}
⇒ Set with 3 elements
⇒
ring R1;
ring R2 = 0,(x,y),dp;
Set S2 = list(R1,R1,R2);
S2;
⇒ {(QQ),(x,y),(dp(2),C); (ZZ/32003),(x,y,z),(dp(3),C)}
⇒ Set with 2 elements
⇒
ideal I1 = x+y;
ideal I2 = y^2;
ideal I3 = x+y, (x+y)^3;
Set S3 = list(I1,I2,I3);
S3;
⇒ {y2; x+y}
⇒ Set with 2 elements
⇒
isEqual(I1,I3);
⇒ 1
isEqual(I1,I2);
⇒ 0
module M1 = x*gen(1), y*gen(1);
module M2 = y^2*gen(2);
module M3 = (x+y)*gen(1), (x-y)*gen(1);
Set S4 = list(M1,M2,M3);
S4;
⇒ {y2*gen(2); x*gen(1),y*gen(1)}
⇒ Set with 2 elements
⇒
intmat m1[2][3]= 1,2,3,4,5,6;
intmat m2[2][3]= 1,2,3,4,5,7;
Set S5 = list(m1,m2,m1);
S5;
⇒ {1,2,3,4,5,7 ; 1,2,3,4,5,6 }
⇒ Set with 2 elements
⇒
bigintmat b1[2][3]= 1,2,3,4,5,6;
bigintmat b2[2][3]= 1,2,3,4,5,7;
Set S6 = list(b1,b2,b1);
S6;
⇒ {1, 2, 3, 4, 5, 7; 1, 2, 3, 4, 5, 6}

```

D.14.8.2 union

Procedure from library `sets.lib` (see [Section D.14.8 \[sets.lib\]](#), page 2272).

Usage: `union(N,M)` or `N+M`; N, M sets

Return: Set, the union of the sets N and M

Example:

```
LIB "sets.lib";
list l =1,2,3;
list j =2,3,4;
Set N=l;
Set M=j;
N;
⇒ {3; 2; 1}
⇒ Set with 3 elements
⇒
M;
⇒ {4; 3; 2}
⇒ Set with 3 elements
⇒
N+M;
⇒ {1; 4; 3; 2}
⇒ Set with 4 elements
⇒
```

D.14.8.3 intersectionSet

Procedure from library `sets.lib` (see [Section D.14.8 \[sets.lib\]](#), page 2272).

Usage: `intersectionSet(N,M)` or `N*M`; N, M sets

Return: Set, the interseection of the sets N and M

Example:

```
LIB "sets.lib";
list l =1,2,3;
list j =2,3,4;
Set N=l;
Set M=j;
N;
⇒ {3; 2; 1}
⇒ Set with 3 elements
⇒
M;
⇒ {4; 3; 2}
⇒ Set with 3 elements
⇒
N*M;
⇒ {3; 2}
⇒ Set with 2 elements
⇒
```

D.14.8.4 complement

Procedure from library `sets.lib` (see [Section D.14.8 \[sets.lib\]](#), page 2272).

Usage: `complement(N,M)`; N, M sets

Return: Set, the complement of the set N in M

Example:

```
LIB "sets.lib";
list l =1,2;
list j =1,2,3,4;
Set N=l;
Set M=j;
N;
⇒ {2; 1}
⇒ Set with 2 elements
⇒
M;
⇒ {4; 3; 2; 1}
⇒ Set with 4 elements
⇒
complement(N,M);
⇒ {3; 4}
⇒ Set with 2 elements
⇒
```

D.14.8.5 isElement

Procedure from library `sets.lib` (see [Section D.14.8 \[sets.lib\]](#), page 2272).

Usage: `isElement(a,M)`; M set a def

Return: bool, 1 if a is an element of M, 0 if not

Example:

```
LIB "sets.lib";
int i=1;
int j=5;
list k =1,2,3,4;
Set M=k;
i;
⇒ 1
j;
⇒ 5
M;
⇒ {4; 3; 2; 1}
⇒ Set with 4 elements
⇒
isElement(i,M);
⇒ 1
isElement(j,M);
⇒ 0
```

D.14.8.6 isSubset

Procedure from library `sets.lib` (see [Section D.14.8 \[sets.lib\]](#), page 2272).

Usage: `isSubset(N,M)` or `N<M` ; N,M sets

Return: bool, 1 if N is a Subset of M or 0 if not

Example:

```

LIB "sets.lib";
list l =1,2;
list j =1,2,3,4;
Set N=l;
Set M=j;
N;
⇒ {2; 1}
⇒ Set with 2 elements
⇒
M;
⇒ {4; 3; 2; 1}
⇒ Set with 4 elements
⇒
N<M;
⇒ 1
M<N;
⇒ 0

```

D.14.8.7 isSuperset

Procedure from library `sets.lib` (see [Section D.14.8 \[sets.lib\]](#), page 2272).

Return: bool, 1 if N is a Superset of M or 0 if not

Example:

```

LIB "sets.lib";
list l =1,2;
list j =1,2,3,4;
Set N=l;
Set M=j;
N;
⇒ {2; 1}
⇒ Set with 2 elements
⇒
M;
⇒ {4; 3; 2; 1}
⇒ Set with 4 elements
⇒
N>M;
⇒ 0
M>N;
⇒ 1

```

D.14.8.8 addElement

Procedure from library `sets.lib` (see [Section D.14.8 \[sets.lib\]](#), page 2272).

Usage: addElement(M,a) ; M Set, a freely chosen element

Return: adds the Element a to the Set M

Example:

```

LIB "sets.lib";
//example for addElement

```

```

int a=4;
list L = 1,2,3;
Set S = L;
S;
↳ {3; 2; 1}
↳ Set with 3 elements
↳
a;
↳ 4
addElement(S,a);
↳ {1; 2; 3; 4}
↳ Set with 4 elements
↳

```

D.15 Experimental libraries

This sections collect libraries in the beta test phase. Everything in these libraries may change. For the minimal requirements and guidelines see [Section 3.8 \[Libraries\]](#), page 55. Comments should be send to the author of the library directly.

D.15.1 arnold_lib

Library: arnold.lib

Purpose: Classification of isolated singularities with a nondegenerate Newton Boundary

Authors: Janko Boehm, email: boehm@mathematik.uni-kl.de
 Magdaleen Marais, email: msmarais@sun.ac.za
 Gerhard Pfister, email: pfister@mathematik.uni-kl.de

Overview: We classify isolated singularities at 0 which is equivalent to a nondegenerate Newton boundary of corank ≤ 2 with respect to right- and stable equivalence. We do this by giving a unique normal form corresponding to a normalized nondegenerate Newton boundary. We furthermore determine the normal form equation, that is a polynomial in the given normal form family of the input polynomial. In addition we determine the Milnor number, modality, delta invariant and the number of branches of an input polynomial that is equivalent to a germ with a nondegenerate Newton boundary in a new alternative efficient way, as well as, a regular basis of a germ with a nondegenerate Newton boundary.

V.I. Arnold has listed normal forms for all isolated hypersurface singularities over the complex numbers with, in particular, either modality ≤ 2 or Milnor number ≤ 16 . Moreover, he has described an algorithmic classifier, which determines the type of a given such singularity.

This library extends Arnold's work to a large class of singularities which is unbounded with regard to modality and Milnor number. It implements an algorithmic classifier, which determines a normal form, as well as a normal form equation, for any corank ≤ 2 singularity which is equivalent to a germ with non-degenerate Newton boundary in the sense of Kouchnirenko.

The implementation is based on the papers:

Janko Boehm, Magdaleen Marais, Gerhard Pfister: Classification of Complex Singularities with Non-Degenerate Newton Boundary,
<https://doi.org/10.48550/arXiv.2010.10185>

Janko Boehm, Magdaleen Marais, Gerhard Pfister: Moduli Parameters of Complex Singularities with Non-Degenerate Newton Boundary,
<https://doi.org/10.48550/arXiv.2402.05093>

General assumption: the input polynomial is given in a ring with ordering ds;

Acknowledgements: This research was supported by the Rubbi fund of the Department of Mathematical Sciences of Stellenbosch University, DFG SPP 1489, DFG TRR 195 (Project B5).

Procedures: See also: [Section D.6.3 \[arnoldclassify_lib\]](#), page 1644; [Section D.6.5 \[classify2_lib\]](#), page 1659; [Section D.6.4 \[classify_lib\]](#), page 1650; [Section D.6.19 \[realclassify_lib\]](#), page 1750.

D.15.1.1 poshull

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold_lib\]](#), page 2277).

Usage: `poshull(L)`; L list

Return: the cone generated by the integer vectors in L

Example:

```
LIB "arnold.lib";
ring R=0,(x,y),ds;
intvec v1 = 1,1;
intvec v2=1,2;
def c = poshull(list(v1,v2));
c;
↳ AMBIENT_DIM
↳ 2
↳ FACETS
↳ -1, 1,
↳ 2,-1
↳ LINEAR_SPAN
↳
↳
```

D.15.1.2 facetsAsCones

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold_lib\]](#), page 2277).

D.15.1.3 monomials

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold_lib\]](#), page 2277).

Usage: `monomials(f)`; f poly

Return: the set of monomials of f as a list

Example:

```
LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = 2*x^2+5*x*y+7*x^7;
monomials(f);
```

```

↳ [1]:
↳      x2
↳ [2]:
↳      xy
↳ [3]:
↳      x7

```

D.15.1.4 coeff

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\]](#), page 2277).

Usage: `coeff(f,m);` `f` poly, `m` poly

Return: the coefficient of `m` in `f`

Example:

```

LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = 2*x^2+5*x*y+7*x^7;
poly m = x*y;
coeff(f,m);
↳ 5

```

D.15.1.5 newtonPolygon

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\]](#), page 2277).

Usage: `newtonPolygon(f);` poly `f`

Return: a list with an entry for each of the finite facets of `f`; each entry consists out of a list with first entry the normal vector of the corresponding facet and second entry a list containing the coordinates of the vertices of the corresponding facet

Example:

```

LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8;
newtonPolygon(f);
↳ [1]:
↳   [1]:
↳     2,1
↳   [2]:
↳     [1]:
↳       0,8
↳     [2]:
↳       2,4
↳ [2]:
↳   [1]:
↳     1,1
↳   [2]:
↳     [1]:
↳       2,4
↳     [2]:
↳       4,2
↳ [3]:

```

```

↳      [1]:
↳      2,5
↳      [2]:
↳      [1]:
↳      4,2
↳      [2]:
↳      9,0

```

D.15.1.6 verticesOfNP

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\], page 2277](#)).

Usage: `verticesOfNP(NP)`; NP list as given by `@ref(newtonPolygon)`

Return: the vertices of the Newton polygon NP as a list

Example:

```

LIB "arnold.lib";
ring R=(0),(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8;
list NP = newtonPolygon(f);
verticesOfNP(NP);
↳ [1]:
↳ 0,8
↳ [2]:
↳ 2,4
↳ [3]:
↳ 4,2
↳ [4]:
↳ 9,0

```

D.15.1.7 termsOnPolygon

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\], page 2277](#)).

Usage: `termsOnPolygon(f, NP)`; poly f, NP list as given by `@ref(newtonPolygon)`

Return: the sum of the terms of f on the Newton polygon NP

Example:

```

LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8+x^3*y^5+y^2*x^5;
list NP = newtonPolygon(f);
termsOnPolygon(f,NP);
↳ x4y2+x2y4+y8+x9

```

D.15.1.8 latticePoints

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\], page 2277](#)).

Usage: `latticePoints(NP)`; NP list as given by `@ref(newtonPolygon)`

Return: a list of all the points lying on NP

Example:

```

LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8+x^3*y^5+y^2*x^5;
list NP = newtonPolygon(f);
latticePoints(NP);
⇒ [1]:
⇒ 0,8
⇒ [2]:
⇒ 1,6
⇒ [3]:
⇒ 2,4
⇒ [4]:
⇒ 3,3
⇒ [5]:
⇒ 4,2
⇒ [6]:
⇒ 9,0

```

D.15.1.9 latticeToMonomials

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\], page 2277](#)).

Usage: `latticeToMonomials(L)`; a list `L` of points in N^2

Return: a list of monomials corresponding to the points in `L`

Example:

```

LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8+x^3*y^5+y^2*x^5;
list NP = newtonPolygon(f);
list L =latticePoints(NP);
latticeToMonomials(L);
⇒ [1]:
⇒ y8
⇒ [2]:
⇒ xy6
⇒ [3]:
⇒ x2y4
⇒ [4]:
⇒ x3y3
⇒ [5]:
⇒ x4y2
⇒ [6]:
⇒ x9

```

D.15.1.10 terms

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\], page 2277](#)).

Usage: `terms(f)`; `poly f`

Return: a list of the terms of `f`

Example:

```

LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = 2*x^9+5*x^2*y^4+10*y^2*x^4+11*y^8+x^3*y^5+21*y^2*x^5;
terms(f);
↳ [1]:
↳ 10x4y2
↳ [2]:
↳ 5x2y4
↳ [3]:
↳ 21x5y2
↳ [4]:
↳ x3y5
↳ [5]:
↳ 11y8
↳ [6]:
↳ 2x9

```

D.15.1.11 piecewiseWeightOfPolygon

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\], page 2277](#)).

Usage: `piecewiseWeightOfPolygon(NP)`; a list NP as given by `@ref(newtonPolygon)`

Return: the piecewiseweight defined by the Newton polygon NP

Example:

```

LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8+x^3*y^5+y^2*x^5;
list NP = newtonPolygon(f);
piecewiseWeightOfPolygon(NP);
↳ [1]:
↳ 18,9
↳ [2]:
↳ 12,12
↳ [3]:
↳ 8,20

```

D.15.1.12 piecewiseOrd

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\], page 2277](#)).

Usage: `piecewiseOrd(f,w)`; f poly, w a piecewise weight given by a list, which can be computed using `@ref(piecewiseWeightOfPolygon)`

Return: the piecewiseOrd with regard to the weight w of f

Example:

```

LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8+x^3*y^5+y^2*x^5;
list NP = newtonPolygon(f);
list w = piecewiseWeightOfPolygon(NP);
piecewiseOrd(f,w);
↳ 72

```

D.15.1.13 piecewisedegree

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\]](#), page 2277).

Usage: `piecewisedegree(f,w)`; f poly, w a piecewise weight given by a list, which can be computed using `@ref(piecewiseWeightOfPolygon)`

Return: the piecewise degree of f , with regard to the weight w

Example:

```
LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8+x^3*y^5+y^2*x^5;
list NP = newtonPolygon(f);
list w = piecewiseWeightOfPolygon(NP);
piecewisedegree(f,w);
↦ 96
```

D.15.1.14 piecewiseJet

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\]](#), page 2277).

Usage: `piecewiseJet(f,w,d)`; f poly, w a piecewise weight given by a list, which can be computed using `@ref(piecewiseWeightOfPolygon)`, d int

Return: the piecewise d -jet of f , with regard to the weight w

Example:

```
LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8+x^3*y^5+y^2*x^5;
list NP = newtonPolygon(f);
list w = piecewiseWeightOfPolygon(NP);
int d = piecewiseOrd(f,w);
piecewiseJet(f,w,d);
↦ x4y2+x2y4+y8+x9
```

D.15.1.15 regularBasis

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\]](#), page 2277).

D.15.1.16 determineNormalForm

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\]](#), page 2277).

Usage: `determineNormalForm(F)`; F poly

Return: if $F.value$ is right equivalent to a germ with a nondegenerate Newton boundary an N of type `NormalForm` with fields:

$N.inputRing$: the ring $F.in$

$N.numbervars$: the embedding dimension (given as type `int`)

$N.normalForm$: a normal form of $F.value$ (given as type `Poly`)

$N.singularityType$: the corner points of the Newton boundary of the normal form of

F.value, which classifies the singularity type (given as type string)

N.parameters: the monomials corresponding to the moduli terms in N.normalForm (given as a list with entries of type poly)

N.corank: the corank of the singularity defined by F.value (given as type int)

N.modality: the modality of the singularity defined by F.value (given as type int)

N.milnorNumber: the Milnor number of F.value (given as type int)

N.delta: the Delta invariant of F.value (given as type int)

N.numberOfBranches: the number of branches of F.value (given as type int)

N.determinacy: a determinacy bound for F.value (given as type int)

N.nondegeneratePart: the nondegenerate part of the normal form of F.value (given as type Poly)

N.nonNormalizedNNBGerm: a polynomial that is stable equivalent to F.value with a nondegenerate Newton boundary (that is not necessarily normalized, given as type Poly)

N.normalizedNNBGerm: a polynomial that is stable equivalent to F.value with a normalized nondegenerate Newton boundary up to scalar multiplication of each of its variables (given as type Poly)

N.phiBeforeMorseSplit: the transformations (and in some cases their inverses) of the transformations that was transformed on F.value to write F.value as a direct sum of its degenerate and nondegenerate parts, given up to filtration d, where d is a determinacy bound for F.value (given as type RightEquivalenceChainWithPrecision as defined in @ref(polyclass.lib))

N.phi: the transformations (and in some cases their inverses) of the transformations that was transformed on the degenerate part of F.value to transform it to a germ with nondegenerate Newton boundary (in some cases the transformations normalize the Newton boundary is also given), is given up to filtration d, where d is a determinacy bound for F.value (given as type RightEquivalenceChainWithPrecision as defined in @ref(polyclass.lib)),

an ERROR message otherwise

Example:

```
LIB "arnold.lib";
ring R = 0,(x,y,z),ds;
poly g = (x^2+y^2)^2+5*x^(10)+y^(11)+z^2;
poly phix = x+y^2+x^2+x*y+x^2*y+x*y^3;
poly phiy = y+y^2+2*x^2+x*y+y*x^2+y^2*x+x*y^4;
poly phiz = z+2x+x^2+y^4*x;
```

```

map phi = R,phix,phiy,phiz;
g = phi(g);
Poly F = makePoly(g);
determineNormalForm(F);
↳ Embedding dimension = 3
↳ Corank of singularity = 2
↳ Normalform of type = (0,22),(1,6),(2,2),(6,1),(22,0)
↳ Normalform = (a(1))*x^2*y^2+x^6*y+x*y^6+x^22+y^22
↳ Normalform equation is not determined.
↳ Milnor number = 21
↳ Modality = 1
↳ Monomials corresponding to moduli terms = x2y2
↳ Delta invariant = 12

↳ Determinacy <= 10
↳ Nondegenerate part = z2
↳ Chain of transformations before Morse split of length 5
↳ Chain of transformations after Morse split of length 5
↳
↳ The chain of transformations is only containing transformations up to tra\
nsforming the input polynomial to a germ with a nondegenerate Newton boun\
dary. The final transformations to normalize the germ are not yet determi\
ned.
↳

```

D.15.1.17 determineNormalFormEquation

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\]](#), page 2277).

Usage: `determineNormalFormEquation(N)`; `N` a NormalForm as given by `@ref(NormalForm)`

Return: a normalform equation, stored in `N.normalFormEquation`, occurring in the normalform, stored in `N.normalForm`, of the polynomial, stored in `N.phi.sourcegerm`, as well as polynomials, stored in `N.extension1` and `N.extension2` (of type `Poly`), defining the parameters, given as ring variables in `N.normalFormEquation`.

Example:

```

LIB "arnold.lib";
ring R=0,(x,y),ds;
poly g = x4+2*x2y2+y4+x^(10)+y^(10);
poly phix = x+y^2+x^2+x*y+x^2*y+x*y^3;
poly phiy = y+y^2+2*x^2+x*y+y*x^2+y^2*x+x*y^4;
map phi = R,phix,phiy;
g=phi(g);
Poly F = makePoly(g);
NormalForm N;
N = determineNormalForm(F);
determineNormalFormEquation(N);
↳ Embedding dimension = 2

D.15.1.18 nondegeneratePart

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\], page 2277](#)).

Usage: `nondegeneratePart(N)`; N NormalForm as given by `@ref(determineNormalForm)`

Return: the nondegenerate part, returned as type Poly, of the singularity defined by `N.phi.sourcegerm.value`

Example:

```

LIB "arnold.lib";
ring R = 0,(x,y,z),ds;
poly g = (x^2+y^2)^2+5*x^(10)+y^(11)+z^2;
poly phix = x+y^2+x^2+x*y+x^2*y+x*y^3;
poly phiy = y+y^2+2*x^2+x*y+y*x^2+y^2*x+x*y^4;
poly phiz = z+2x+x^2+y^4*x;

D.15.1.19 germWithNNB

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\], page 2277](#)).

Usage: `germWithNNB(N)`; N NormalForm as given by `@ref(determineNormalForm)`

Return: a germ with a nondegenerate Newton boundary, returned as type Poly, that is stable equivalent to `N.phi.sourcegerm.value`, if possible, or an ERROR message otherwise

Example:

```

LIB "arnold.lib";
ring R = 0,(x,y),ds;
poly g = (x^2+y^2)^2+5*x^(10)+y^(11);
poly phix = x+y^2+x^2+x*y+x^2*y+x*y^3;
poly phiy = y+y^2+2*x^2+x*y+y*x^2+y^2*x+x*y^4;

D.15.1.20 germWithNormalizedNNB

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\]](#), page 2277).

Usage: `germWithNormalizedNNB(N);` `N` `NormalForm` as given by
`@ref(determineNormalForm)`

Return: a polynomial, returned as a Poly, that is stable equivalent to `N.phi.sourcegerm.value` with a normalized nondegenerate Newton boundary up to scalar multiplication of each of its variables, if possible, or an ERROR message otherwise

Example:

```

LIB "arnold.lib";
ring R = 0,(x,y),ds;
poly g = (x^2+y^2)^2+5*x^(10)+y^(11);
poly phix = x+y^2+x^2+xy+x^2*y+xy^3;
poly phiy = y+y^2+2*x^2+xy+y*x^2+y^2*x+xy^4;
map phi = R,phix,phiy;
g = phi(g);
Poly F = makePoly(g);
NormalForm N = determineNormalForm(F);
germWithNNB(N);
↳ x2y2+(3a+5/2)*x3y2+(-3a+5/2)*x2y3+(13/4a-15/16)*x4y2+27/2*x3y3+(-13/4a-15\

D.15.1.21 modalityNNB

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\]](#), page 2277).

Usage: `modalityNNB(f,w)`; `f` poly or Poly or NormalForm

Return: the modality of `f` (or `f.value` or `f.phi.sourcegerm.value`), if `f` (or `f.value` or `f.phi.sourcegerm.value`) is equivalent to a germ with a nondegenerate Newton boundary,
or an ERROR message otherwise

Example:

```
LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8+x^3*y^5+y^2*x^5;
poly phix = x+y^2+x^2*x*y+x^2*y+x*y^3;
poly phiy = y+y^2+2*x^2+x*y+y*x^2+y^2*x+x*y^4;
map phi = R,phix,phiy;
f = phi(f);                      // f is equivalent to a germ with a nondegenerate
Poly F = makePoly(f);
NormalForm N;
N = determineNormalForm(F);
modalityNNB(f);
↳ 6
modalityNNB(F);
↳ 6

↳ 6
```

D.15.1.22 milnorNNB

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\]](#), page 2277).

Usage: `milnorNNB(f,w)`; `f` poly or Poly or NormalForm

Return: the Milnor number of `f` (or `f.value` or `f.phi.sourcegerm.value`), if `f` (or `f.value` or `f.phi.sourcegerm.value`) is equivalent to a germ with a nondegenerate Newton boundary,
or an ERROR message otherwise

Example:

```
LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8+x^3*y^5+y^2*x^5;
poly phix = x+y^2+x^2*x*y+x^2*y+x*y^3;
poly phiy = y+y^2+2*x^2+x*y+y*x^2+y^2*x+x*y^4;
map phi = R,phix,phiy;
f = phi(f);                      // f is equivalent to a germ with a nondegenerate
Poly F = makePoly(f);
NormalForm N = determineNormalForm(F);
milnorNNB(f);
↳ 30
milnorNNB(F);
↳ 30
milnorNNB(N);
↳ 30
```

D.15.1.23 determinacyBound

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\], page 2277](#)).

Usage: `determinacyBound(f);` `f` poly or Poly or NormalForm

Return: an upper bound for the determinacy bound of `f` (or `f.value` or `f.phi.sourcegerm.value`)

Example:

```
LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8+x^3*y^5+y^2*x^5;
Poly F = makePoly(f);
NormalForm N = determineNormalForm(F);
determinacyBound(f);
⇒ 11
determinacyBound(F);
⇒ 11
determinacyBound(N);
⇒ 11
```

D.15.1.24 deltaNNB

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\], page 2277](#)).

Usage: `deltaNNB(f);` `f` poly or Poly or NormalForm

Return: a List with entries `d,n`, where `d` is the Delta invariant and `n` is the number of branches of `f` (or `f.value` or `f.phi.sourcegerm.value`), if `f` (or `f.value` or `f.phi.sourcegerm.value`) is equivalent to a germ with a nondegenerate Newton Boundary, or an ERROR message otherwise

Example:

```
LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8+x^3*y^5+y^2*x^5;
Poly F = makePoly(f);
NormalForm N = determineNormalForm(F);
deltaNNB(f);

⇒ [1]:
⇒ 17
⇒ [2]:
⇒ 5
```

D.15.1.25 moduliMonomials

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\], page 2277](#)).

Usage: `moduliMonomials(N);` `N` NormalForm

Return: the list of the moduli monomials of the normal form `N.normalForm`

Example:

```
LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8+x^3*y^5+y^2*x^5;
Poly F = makePoly(f);
NormalForm N = determineNormalForm(F);
moduliMonomials(N);
⇒ [1]:
⇒ x4y4
⇒ [2]:
⇒ x4y3
⇒ [3]:
⇒ x3y4
⇒ [4]:
⇒ x4y2
⇒ [5]:
⇒ x3y3
⇒ [6]:
⇒ x2y4
```

D.15.1.26 newtonNumber

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\], page 2277](#)).

Usage: `newtonNumber(F);` `F` poly or Poly

Return: the Newton number of `F` (or `F.value`)

Example:

```
LIB "arnold.lib";
ring R=0,(x,y),ds;
poly f = x^9+x^2*y^4+y^2*x^4+y^8+x^3*y^5+y^2*x^5;
Poly F = makePoly(f);
newtonNumber(F);
⇒ 30
newtonNumber(f);
⇒ 30
```

D.15.1.27 transformationsBeforeSplit

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\], page 2277](#)).

Usage: `transformationsBeforeSplit(N);` `N` NormalForm as given by `@ref(determineNormalForm)`

Return: the transformations (and in some cases their inverses) that was transformed on `N.phi.sourcegerm.value` to write it as a direct sum of its degenerate and nondegenerate parts,
given up to filtration `d`, where `d` is a determinacy bound for `F.value` (returned as type `RightEquivalenceChainWithPrecision` as defined in `@ref(polyclass.lib)`)

Example:

```

LIB "arnold.lib";
ring R = 0,(x,y,z),ds;
poly g = (x^2+y^2)^2+5*x^(10)+y^(11)+z^2;
poly phix = x+y^2+x^2+x*y+x^2*y+x*y^3;
poly phiy = y+y^2+2*x^2+x*y+y*x^2+y^2*x+x*y^4;
poly phiz = z+2x+x^2+y^4*x;
map phi = R,phix,phiy,phiz;
g = phi(g);
Poly F = makePoly(g);
NormalForm N = determineNormalForm(F);
transformationsBeforeSplit(N);

D.15.1.28 transformationsAfterSplit

Procedure from library `arnold.lib` (see [Section D.15.1 \[arnold.lib\]](#), page 2277).

Usage: `transformationsAfterSplit(N)`; `N` NormalForm as given by `@ref(determineNormalForm)`

Return: the transformations (and in some cases their inverses) that was transformed, after the degenerate part was splitted off, of `N.phi.sourcegerm.value` to transform it to a germ with nondegenerate Newton boundary (in some cases the transformations normalize the Newton boundary is also given), is given up to filtration `d`, where `d` is a determinacy bound for `N.source` (returned as type `RightEquivalenceChainWithPrecision` as defined in `@ref(polyclass.lib)`)

Example:

```

LIB "arnold.lib";
ring R = 0,(x,y,z),ds;
poly g = (x^2+y^2)^2+5*x^(10)+y^(11)+z^2;
poly phix = x*y^2+x^2+x*y+x^2*y+x*y^3;
poly phiy = y*y^2+2*x^2+x*y+y*x^2+y^2*x+x*y^4;

```

```

poly phiz = z+2x+x^2+y^4*x;
map phi = R,phix,phiy,phiz;
g = phi(g);
Poly F = makePoly(g);
NormalForm N = determineNormalForm(F);
transformationsAfterSplit(N);
↳
↳ The transformations are only given up to transforming the input polynomial
  1 to a germ with a nondegenerate Newton boundary. The final transformations
  to normalize the germ are not yet determined.

D.15.2 autgradalg_lib

Library: autgradalg.lib

Purpose: Compute automorphism groups of pointedly graded algebras and of Mori dream spaces.

Authors: Simon Keicher

Overview: This library provides a framework for computing automorphisms of integral, finitely generated algebras that are graded by a finitely generated abelian group. This library also contains functions to compute automorphism groups of Mori dream spaces. The results are ideals I such that the respective automorphism group is isomorphic to the subgroup $V(I)$ in some $GL(n)$.

Assumptions:

* the algebra R is given as factor algebra S/I with a graded polynomial ring $S = KK[T_1, \dots, T_r]$. We will always assume that the basering is S and it is given over the rationals QQ or a number field $QQ(a)$. * R must be minimally presented, i.e., I is contained in $\langle T_1, \dots, T_r \rangle^2$. * S (and hence R) are graded via 'setBaseMultigrading(Q)' from 'multigrading.lib'. The last rows of the matrix Q are interpreted over $\mathbb{Z}\mathbb{Z}/a_i\mathbb{Z}\mathbb{Z}$ if the respective entry of the list TOR is a_i and has been provided as parameter to the respective function. (See the functions for more details.) * For all $1 \leq i \leq r$: $L_{w_i} = 0$ where $w_i := \deg(T_i)$. * the grading is pointed, i.e., no generator has degree 0 and the cone over all generator degrees is pointed. * For Mori dream spaces X , we assume them to be given as $X = X(R, w)$ with the Cox ring R of X (given as the algebra R before) and an ample class w in the grading group K with the torsion entries removed.

Procedures:

Note: the following functions were taken from 'quotsingcox.lib' by M.Donten-Bury and S.Keicher: 'hilbertBas'.

Note: This library comes without any warranty whatsoever. Use it at your own risk.

D.15.2.1 autKS

Procedure from library `autgradalg.lib` (see [Section D.15.2 \[autgradalg_lib\]](#), page 2297).

Usage: `autKS(TOR)`; TOR : optional list of elementary divisors in case of torsion.

Assume: the basering is multigraded having used the command `setBaseMultigrading(Q)` from 'multigrading.lib'.

Purpose: Compute the subgroup $\text{Aut}_K(S)$ of $GL(n)$ of graded automorphisms of the polynomial ring S (the basering).

Return: returns a ring S and exports an ideal `ideal` I_{exported} in the coordinate ring $S = K[Y_{ij}]$ of $GL(n)$ such that $\text{Aut}_K(S) = V(I)$.

Example:

D.15.2.2 autGradAlg

Procedure from library `autgradalg.lib` (see [Section D.15.2 \[autgradalg.lib\]](#), page 2297).

Usage: `autGradAlg(I, TOR);` I is an ideal, TOR is an optional list of integers representing the torsion part of the grading group.

Assume: minimally presented, degrees of the generators of I
are the minimal degrees, basering multigraded pointedly, $I_w = 0$ for all $w = \deg(\text{var}(i))$

Return: a ring. Also exports an ideal `Jexported` and a list `stabExported`.

Example:

```

LIB "autgradalg.lib";
⇒ // ** redefining fullSpace ( LIB "gfan.lib"); gitfan.lib::mod_init:86

D.15.2.3 autGenWeights

Procedure from library `autgradalg.lib` (see [Section D.15.2 \[autgradalg.lib\]](#), page 2297).

Usage: `autGenWeights(Q)`: Q is an intmat (columns must contain a lattice basis).

Assume: the cone over Q must be pointed and the columns of Q contain a lattice basis; there must be no 0-columns in Q . We assume that, in the torsion case, the torsion rows of Q are reduced (for example, a row of Q standing for entries in $\mathbb{Z}\mathbb{Z}/5\mathbb{Z}\mathbb{Z}$ must not contain elements > 5 or < 0).

Purpose: computes generators for the subgroup $\text{aut}(\Omega_S)$ of $\text{GL}(n, \mathbb{Z})$ that consists of all invertible integer $k \times k$ matrices which fix the set Ω_S of degrees of the variables of the basering S . The set of columns of Q equals Ω_S .

Reference:
Remark 3.1.

Return: a list of integral matrices A with $|\det A| = 1$ such that $A \cdot \{\text{columns of } Q\} = \{\text{columns of } Q\}$.

Example:

```

D.15.2.4 stabilizer

Procedure from library `autgradalg.lib` (see [Section D.15.2 \[autgradalg.lib\]](#), page 2297).

Usage: `stabilizer(RL, A, BB, AMON, n0)`: `RL` is an ideal, `A` a matrix (standing for a subgroup of $GL(n)$), `BB` is an `intmat` (standing for an automorphism of the grading group), `AMON` a list of monomials corresponding to the rows/columns of `A`, `n0` an integer such that the first `n0` variables of the basering are the $T(i)$, optional: a list of elementary divisors if there is torsion.

Assume: the basering must be graded (see `setBaseMultigrading()`) and the cone over the degrees of the variables must be pointed; there mustn't be 0-degrees. The vector `w` must be an element of the cone over the degrees of the variables. Moreover, `B` must be such that it permutes the degrees of the variables and the degrees of the generators of `RL`.

Purpose: returns relations such that $A \cdot I = I$.

Return: a ring. Also exports an ideal `Jexported` and a list `stabExported`.

Example:

```

D.15.2.5 autXhat

Procedure from library `autgradalg.lib` (see [Section D.15.2 \[autgradalg.lib\], page 2297](#)).

Usage: `autXhat(RL, w0, TOR)`: RL is an ideal, w an intvec, TOR a list of integers

Assume: the basering is multigraded, the elements of TOR stand for the torsion rows of the matrix `getVariableWeights()`, w is an ample class or the free part of such a class.

Purpose: compute an ideal J such that $V(J)$ in some $GL(n)$ is isomorphic to the H-equivariant automorphisms $\widehat{X} \rightarrow \widehat{X}$.

Example:

```

LIB "autgradalg.lib";

D.15.2.6 autX

Procedure from library `autgradalg.lib` (see [Section D.15.2 \[autgradalg.lib\]](#), page 2297).

Usage: `autX(RL, w, TOR);` RL: ideal, w: intvec, TOR: optional list of integers.

Purpose: compute generators for the hopf algebra $O(\text{Aut}(X))$ of the Mori dream space X given by $\text{Cox}(X) := \text{basering}/\text{RL}$ and the ample class w .

Assume: there is no torsion.

Return: a ring. Also exports an ideal `Iexported`.

Example:

```

LIB "autgradalg.lib";
↳ // ** redefining fullSpace ( LIB "gfan.lib"); gitfan.lib::mod_init:86

```

D.15.3 difform_lib

Library: difform.lib

Purpose: Procedures for differential forms

Author: Peter Chini, chini@rhrk.uni-kl.de

Overview: A library for computing with elements of the differential algebra over a (quotient) ring. To compute in this algebra, a non-commutative ring with additional variables dx_1, \dots, dx_n and 'exterior' relations between this variables is used. In the case of a quotient ring, the defining ideal and its image under the universal derivation are added as relations. The differential forms themselves are defined via an additional type 'difform'. Objects of this type carry as an attribute a polynomial in the differential algebra and make it available over the basering.

Additionally, the universal derivation is available as a procedure and the differentials between the graded parts of the differential algebra can be applied to differential forms. The library also supports derivations: maps from the first graded part of the differential

algebra to the basering. These are defined via the type 'derivation' and there are procedures for basic arithmetic operations, evaluation and Lie-derivative.

Procedures:

D.15.3.1 diffAlgebra

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Side effects:

If `R` is the basering, the differential algebra is constructed with name `Omega_R` and the differential forms `dx_1,...,dx_n` are available. The name of the differential algebra is stored in the attribute `attrib(R,"diffAlgebra")`.

Note:

- computations with differential forms need the structure of the differential algebra, so this procedure should be executed first.
- the variable names 'd' or 'D' should be avoided.
- the procedure also works for quotient rings

Example:

```
LIB "diffform.lib";
/////////////////////////////////////////////////////////////////
// Example for a differential algebra over a polynomial ring //
/////////////////////////////////////////////////////////////////
ring R = 0,(a,b,c),ds;
diffAlgebra();
⇒ // The differential algebra Omega_R was constructed and the differential \
   forms dDa, dDb, dDc, da, db, dc are available.
setring Omega_R;
// The differential algebra is given by:
basing;
⇒ // coefficients: QQ
⇒ // number of vars : 6
⇒ //      block  1 : ordering dp
⇒ //      : names  Da Db Dc
⇒ //      block  2 : ordering ds
⇒ //      : names  a b c
⇒ //      block  3 : ordering C
⇒ // noncommutative relations:
⇒ //      DbDa=-Da*Db
⇒ //      DcDa=-Da*Dc
⇒ //      DcDb=-Db*Dc
⇒ // quotient ring from ideal
⇒ _[1]=Da^2
⇒ _[2]=Db^2
⇒ _[3]=Dc^2
kill R,Omega_R,da,db,dc;
/////////////////////////////////////////////////////////////////
// Example for a differential algebra over a quotient ring //
/////////////////////////////////////////////////////////////////
ring R = 0,(x,y,z),lp;
ideal I = x+y+z,xyz;
qring S = std(I);
diffAlgebra();
```

```

⇒ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
setring Omega_R;
// The differential algebra is given by:
basing;
⇒ // coefficients: QQ
⇒ // number of vars : 6
⇒ //          block 1 : ordering dp
⇒ //          : names  Dx Dy Dz
⇒ //          block 2 : ordering lp
⇒ //          : names  x y z
⇒ //          block 3 : ordering C
⇒ // noncommutative relations:
⇒ //      DyDx=-Dx*Dy
⇒ //      DzDx=-Dx*Dz
⇒ //      DzDy=-Dy*Dz
⇒ // quotient ring from ideal
⇒ _[1]=y^2*z+y*z^2
⇒ _[2]=x+y+z
⇒ _[3]=Dz*y^4+3*Dz*y^3*z+2*Dz*y^2*z^2
⇒ _[4]=Dy*z^3+2*Dz*y^3+5*Dz*y^2*z+2*Dz*y*z^2
⇒ _[5]=2*Dy*y*z+Dy*z^2+Dz*y^2+2*Dz*y*z
⇒ _[6]=Dx+Dy+Dz
⇒ _[7]=Dy*Dz*y^2+2*Dy*Dz*y*z
⇒ _[8]=Dz^2
⇒ _[9]=Dy^2
⇒ _[10]=Dx^2
kill Omega_R,dx,dy,dz;

```

See also: [Section D.15.3.3 \[diffAlgebraGens\]](#), page 2336; [Section D.15.3.2 \[diffAlgebraStructure\]](#), page 2336; [Section D.15.3.4 \[diffAlgebraUnivDerIdeal\]](#), page 2337.

D.15.3.2 diffAlgebraStructure

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `diffAlgebraStructure();`

Return: the structure of the differential algebra

Remarks: The differential algebra is constructed as non-commutative ring with additional variables Dx_1, \dots, Dx_n and 'exterior' relations between them. In the case, that the basering is a quotient ring, the defining ideal and its image under the universal derivation are added as relations.

Note: the monomial ordering of the basering is preserved in the differential algebra

See also: [Section D.15.3.1 \[diffAlgebra\]](#), page 2335; [Section D.15.3.3 \[diffAlgebraGens\]](#), page 2336; [Section D.15.3.4 \[diffAlgebraUnivDerIdeal\]](#), page 2337.

D.15.3.3 diffAlgebraGens

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `diffAlgebraGens();`

Side effects:

The differential forms dx_1, \dots, dx_n are constructed.

See also: [Section D.15.3.1 \[diffAlgebra\]](#), page 2335; [Section D.15.3.2 \[diffAlgebraStructure\]](#), page 2336; [Section D.15.3.4 \[diffAlgebraUnivDerIdeal\]](#), page 2337.

D.15.3.4 diffAlgebraUnivDerIdeal

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

- Usage:** `diffAlgebraUnivDerIdeal(I); I ideal`
- Assume:** current basering is the differential algebra of a polynomial ring and I is lifted from the polynomial ring
- Return:** the image of I under the universal derivation
- Remark:** The procedure computes the universal derivation of every generator of the ideal.
- Note:** for differential forms use the procedure `diffformUnivDer` or `diffformDiff`

See also: [Section D.15.3.1 \[diffAlgebra\]](#), page 2335; [Section D.15.3.3 \[diffAlgebraGens\]](#), page 2336; [Section D.15.3.2 \[diffAlgebraStructure\]](#), page 2336.

D.15.3.5 diffAlgebraChangeOrd

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

- Usage:** `diffAlgebraChangeOrd(#); # list`
- Assume:** the current basering is the differential algebra
- Return:** the differential algebra with changed monomial ordering
- Note:**
- an ordering is defined via the following pattern:
 - `#[i] = 'gen'` defines the ordering on the generators `dx_i` - `#[i+1]` must then be a valid monomial ordering as string - `#[i+2]` an optional weight vector
 - `#[i] = 'ringvar'` defines the ordering on the ringvariables - `#[i+1]` must then be a valid monomial ordering as string - `#[i+2]` an optional weight vector
 - only use for interior computations
 - differential forms are polynomials in the differential algebra - not in the returned ring - do not define differential forms as polynomials in the returned ring since this is another data-ring - an error occurs if:
 - no valid monomial ordering is given
 - no weight vector is given but a weighted monomial ordering
 - a given weight vector has wrong dimension
 - weight vectors are ignored if the given ordering is not weighted

See also: [Section D.15.3.21 \[diffformIsBigger\]](#), page 2348; [Section D.15.3.22 \[diffformIsSmaller\]](#), page 2349; [Section D.15.3.27 \[diffformListSort\]](#), page 2353.

D.15.3.6 diffAlgebraListGen

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

- Usage:** `diffAlgebraListGen(#); # list`
- Return:** - a list of generators of the differential algebra as module over the basering - a list of generators of a graded part of the differential algebra
- Remarks:** In order to find all generators, they are counted 'binary': The generators are in 1:1 - correspondence to the dual number representations of 1 up to $(2^n - 1)$

Note:

- if all generators of the differential algebra are needed, apply the procedure without input
- if the generator(s) of a graded part are needed, apply the procedure with an integer which specifies the wanted degree
- the list of generators is sorted with respect to the monomial ordering on the differential algebra

Example:

```
LIB "diffform.lib";
ring R = 11,(x,y,z),dp;
diffAlgebra();
⇨ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// Generators of the differential algebra //
////////////////////////////////////
diffAlgebraListGen();
⇨ [1]:
⇨    1
⇨
⇨ [2]:
⇨    dz
⇨
⇨ [3]:
⇨    dy
⇨
⇨ [4]:
⇨    dx
⇨
⇨ [5]:
⇨    dy*dz
⇨
⇨ [6]:
⇨    dx*dz
⇨
⇨ [7]:
⇨    dx*dy
⇨
⇨ [8]:
⇨    dx*dy*dz
⇨
////////////////////////////////////
// Generators of the second graded part //
////////////////////////////////////
diffAlgebraListGen(2);
⇨ [1]:
⇨    dy*dz
⇨
⇨ [2]:
⇨    dx*dz
⇨
⇨ [3]:
⇨    dx*dy
```

```

↳
kill Omega_R,dx,dy,dz;

```

D.15.3.7 diffFromPoly

Procedure from library `diffFromPoly.lib` (see [Section D.15.3 \[diffFromPoly.lib\]](#), page 2334).

Usage: `diffFromPoly df = f; f poly`

Return: the differential form of degree 0 defined by `f`

Remark: The given polynomial gets lifted to the differential algebra and the differential form is defined there.

Example:

```

LIB "diffFromPoly.lib";
ring R = 0,(x,y,z),ds;
diffAlgebra();
↳ // The differential algebra Omega_R was constructed and the differential \
   forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// Construction of differential forms //
////////////////////////////////////
poly f = 3x3z*(y4-y5) + 2;
diffFromPoly df = f;
df;
↳ 2+3x3y4z-3x3y5z
↳
// For the construction of more general differential forms,
// the constructor diffFromPoly is used implicitly:
diffFromPoly dg = 3*x*dx - y*dy + dx*dy*dz + 1;
dg;
↳ 1+3x*dx+(-y)*dy+dx*dy*dz
↳
kill Omega_R,df,dg,dx,dy,dz;

```

D.15.3.8 diffCoef

Procedure from library `diffCoef.lib` (see [Section D.15.3 \[diffCoef.lib\]](#), page 2334).

Usage: `diffCoef(df); df diffFromPoly`

Return: list of lists of differential forms and polynomials:
- the first entry is a generator of the differential algebra which appears in `df` - the second entry is the corresponding coefficient

Remarks: Via the procedure `coef`, the coefficients are found - therefore the ring has to be changed to the differential algebra. After that, the coefficients have to be mapped back to the original ring.

Note: the returned list can be sorted with the procedure `diffFromPolyListSort` and the optional string 'Llist'

Example:

```

LIB "diffFromPoly.lib";
ring R = 0,(x,y,z),lp;
diffAlgebra();

```

```

⇒ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
diffform df = 3*x25*dx - y*dx*dy + 12*dx*dy*dz - dz*dy + 3 + 12*x*dx + 24*(y4-y5) + dz
////////////////////////////////////
// Unsorted Coefficient List //
////////////////////////////////////
list L_1 = diffformCoef(df);
L_1;
⇒ [1]:
⇒   [1]:
⇒     dx*dy*dz

↳ [2]:
↳ 3x25+12x
↳ [7]:
↳ [1]:
↳ 1
↳
↳ [2]:
↳ -24y5+24y4+3
kill Omega_R,df,dx,dy,dz,L_1;

```

D.15.3.9 diffformGenToString

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `diffformGenToString(df);` `df` diffform

Return: the differential form `df` as a string - but with unsorted coefficients

Note: - this is only used to print generators
 - the procedure replaces the 'D' from the variables of the differential algebra by an 'd'

See also: [Section D.15.3.11 \[diffformToString\], page 2342](#).

D.15.3.10 diffformHomogDecomp

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\], page 2334](#)).

Usage: `diffformHomogDecomp(df);` df diffform

Return: list of differential forms: homogeneous decomposition

Note: the output list always has as length the maximal possible degree plus one and the degree-0 part is the last element in the list

Example:

```
LIB "diffform.lib";
ring R = 0,(x,y,z),ds;
diffAlgebra();
⇒ // The differential algebra Omega_R was constructed and the differential \
   forms dDx, dDy, dDz, dx, dy, dz are available.
diffform df = 3*dx*dz - x8*dx*dy + 12 + dy*dz + dz*dx - (y4-y5)*x12*dx*dy*dz - dx - dy
////////////////////////////////////
// Homogeneous decomposition //
////////////////////////////////////
list L = diffformHomogDecomp(df);
L;
⇒ [1]:
⇒ (-1)*dx+(-1)*dy+dz
⇒
⇒ [2]:
⇒ (x2-x8)*dx*dy+2*dx*dz+dy*dz
⇒
⇒ [3]:
⇒ (-x12y4+x12y5)*dx*dy*dz
⇒
⇒ [4]:
⇒ 12
⇒
kill Omega_R,df,L,dx,dy,dz;
```

See also: [Section D.15.3.8 \[diffformCoef\], page 2339](#); [Section D.15.3.23 \[diffformDeg\], page 2350](#).

D.15.3.11 diffformToString

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\], page 2334](#)).

Usage: `diffformToString(df,#);` df diffform, # list

Return: df as a string, sorted by a given ordering on the generators (standard: the ordering chosen for the differential algebra)

Remarks: The differential form is decomposed via `diffformCoef`, the coefficient list is sorted and then the string is built as concatenation of coefficients and generators

Note: to get a string, respecting a certain monomial ordering on the generators, use: - #[1] = 'gen'
 - #[2]: a monomial ordering as string
 - #[3]: an optional weight vector

Example:

```
LIB "diffform.lib";
ring R = 0,(x,y,z,a,b),ds;
diffAlgebra();
⇒ // The differential algebra Omega_R was constructed and the differential \
   forms dDx, dDy, dDz, dDa, dDb, dx, dy, dz, da, db are available.
diffform df = 3*x*dx -2*db + 24*a*dy - y*dx*dy*db + 12*dx*dy*dz - dz*dy*da*db + 3 + 12*x*dz
////////////////////////////////////
// String sorted with respect to the monomial order on the differential algebra //
////////////////////////////////////
string df_str = diffformToString(df);
print(df_str);
⇒ dy*dz*da*db+12*dx*dy*dz+(-y)*dx*dy*db+1/77*dx*da+15x*dx+24a*dy+(-2)*db+3
////////////////////////////////////
// String sorted with respect to the weighted order wp //
////////////////////////////////////
df_str = diffformToString(df,"gen","wp",intvec(-1,-1,-1,1,1));
print(df_str);
⇒ (-2)*db+dy*dz*da*db+1/77*dx*da+3+(-y)*dx*dy*db+15x*dx+24a*dy+12*dx*dy*dz
kill Omega_R,df,df_str,dx,dy,dz,da,db;
```

See also: [Section D.15.3.9 \[diffformGenToString\]](#), page 2341; [Section D.15.3.12 \[diffformPrint\]](#), page 2343.

D.15.3.12 diffformPrint

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: df; df diffform

Side effects:

prints the differential form

Remarks: Uses the procedure `diffformToString` with a `ds`-ordering on the generators

Example:

```
LIB "diffform.lib";
ring R = 0,(x,y,z),ds;
diffAlgebra();
⇒ // The differential algebra Omega_R was constructed and the differential \
   forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// Application of Print //
////////////////////////////////////
diffform df = 3*x*dx - y*dx*dy + 12*dx*dy*dz - dz*dy + 3 + 12*x*dz;
df;
⇒ 3+15x*dx+(-y)*dx*dy+dy*dz+12*dx*dy*dz
⇒
kill Omega_R,df,dx,dy,dz;
```

See also: [Section D.15.3.9 \[diffformGenToString\]](#), page 2341; [Section D.15.3.11 \[diffformToString\]](#), page 2342.

D.15.3.13 diffformIsGen

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `diffformIsGen(df); df diffform`

Return: 1, if `df` is a generator of the differential algebra - 0, otherwise

Remarks: Uses the procedure `diffformCoef` and tests for a single coefficient which is one

Example:

```
LIB "diffform.lib";
ring R = 0,(x,y,z,a,b,c),lp;
diffAlgebra();
⇒ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dDa, dDb, dDc, dx, dy, dz, da, db, dc are available.
//////////
// Generators //
//////////
diffformIsGen(1);
⇒ 1
diffformIsGen(dx);
⇒ 1
diffformIsGen(da*dc);
⇒ 1
diffformIsGen(dy*da*db);
⇒ 1
diffformIsGen(-da*dz);
⇒ 1
//////////
// No generators //
//////////
diffformIsGen(-1);
⇒ 0
diffformIsGen(-dx);
⇒ 0
diffformIsGen(dc*da);
⇒ 0
diffformIsGen(dy*db*da);
⇒ 0
diffformIsGen(dx*dz*dy);
⇒ 0
kill Omega_R,dx,dy,dz,da,db,dc;
```

See also: [Section D.15.3.8 \[diffformCoef\]](#), page 2339.

D.15.3.14 diffformAdd

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `df+dg; df,dg diffform`

Return: the sum of the differential forms as differential form

Example:

```
LIB "diffform.lib";
ring R = 0,(x,y,z),ds;
```

```

diffAlgebra();
⇒ // The differential algebra Omega_R was constructed and the differential \
   forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// Addition of differential forms //
////////////////////////////////////
diffform df = dx + 4*dy - dz*dx + 4 + 3*dx*dy + 4*dz;
diffform dg = dx + dy + 27*dz*dy;
df+dg;
⇒ 4+2*dx+5*dy+4*dz+3*dx*dy+dx*dz+(-27)*dy*dz
⇒
////////////////////////////////////
// Addition of polynomials and differential forms //
////////////////////////////////////
df + x2y2z2;
⇒ 4+x2y2z2+dx+4*dy+4*dz+3*dx*dy+dx*dz
⇒
12 + dg;
⇒ 12+dx+dy+(-27)*dy*dz
⇒
kill Omega_R,df,dg,dx,dy,dz;

```

See also: [Section D.15.3.15 \[diffformSub\]](#), page 2345.

D.15.3.15 diffformSub

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform_lib\]](#), page 2334).

Usage: `df-dg; df,dg diffform`

Return: the difference of the differential forms as differential form

Example:

```

LIB "diffform.lib";
ring R = 0,(x,y,z),ds;
diffAlgebra();
⇒ // The differential algebra Omega_R was constructed and the differential \
   forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// Subtraction of differential forms //
////////////////////////////////////
diffform df = 5*dx*x2 - 7*dy*z - 2x2*dz - 3;
diffform dg = dx - 8x*dz*dy;
df-dg;
⇒ -3+(-1+5x2)*dx+(-7z)*dy+(-2x2)*dz+(-8x)*dy*dz
⇒
////////////////////////////////////
// Subtraction of polynomials and differential forms //
////////////////////////////////////
df - 2x3;
⇒ -3-2x3+5x2*dx+(-7z)*dy+(-2x2)*dz
⇒
1 - dg;
⇒ 1+(-1)*dx+(-8x)*dy*dz
⇒

```

```
kill Omega_R,df,dg,dx,dy,dz;
```

See also: [Section D.15.3.14 \[diffformAdd\]](#), page 2344; [Section D.15.3.16 \[diffformNeg\]](#), page 2346.

D.15.3.16 diffformNeg

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `-df; df diffform`

Return: the negation of the differential form

Example:

```
LIB "diffform.lib";
ring R = 0,(x,y,z),ds;
diffAlgebra();
⇨ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// Negation of a differential form //
////////////////////////////////////
diffform df = 13*dx*dy + 2*dy*dz - 6*dx*dy*dz - 3;
-df;
⇨ 3+(-13)*dx*dy+(-2)*dy*dz+6*dx*dy*dz
⇨
kill Omega_R,df,dx,dy,dz;
```

See also: [Section D.15.3.15 \[diffformSub\]](#), page 2345.

D.15.3.17 diffformMul

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `df*dg; df,dg diffform`

Return: the product of the differential forms as differential form

Example:

```
LIB "diffform.lib";
ring R = 0,(x,y,z),ds;
diffAlgebra();
⇨ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// Multiplication of differential forms //
////////////////////////////////////
diffform df = 13*dx*dy - 7*dy*dz - 6*dx*dy*dz;
diffform dg = dx - 8x;
df*dg;
⇨ (-104x)*dx*dy+56x*dy*dz+(-7+48x)*dx*dy*dz
⇨
////////////////////////////////////
// Multiplication of polynomials and differential forms //
////////////////////////////////////
df*(y^2-x);
⇨ (-13x+13y^2)*dx*dy+(7x-7y^2)*dy*dz+(6x-6y^2)*dx*dy*dz
⇨
```

```

12*dg;
 $\mapsto -96x+12*dx$ 
 $\mapsto$ 
kill Omega_R,df,dg,dx,dy,dz;

```

See also: [Section D.15.3.18 \[diffformDiv\]](#), page 2347.

D.15.3.18 diffformDiv

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `df/dg; df,dg diffform`

Return: the quotient `df/dg` as differential form

Example:

```

LIB "diffform.lib";
ring R = 0,(x,y,z),lp;
diffAlgebra();
 $\mapsto$  // The differential algebra Omega_R was constructed and the differential \
      forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// Divisions without remainder //
////////////////////////////////////
dx / dx;
 $\mapsto 1$ 
 $\mapsto$ 
dx*dy*dz / dz;
 $\mapsto dx*dy$ 
 $\mapsto$ 
(dx*x2 - yx2) / x2;
 $\mapsto -y+dx$ 
 $\mapsto$ 
////////////////////////////////////
// Divisions with reaminder //
////////////////////////////////////
(dx + dx*dy + 1) / dx;
 $\mapsto 1+(-1)*dy$ 
 $\mapsto$ 
(x2*dx - x*dy) / (dx-dy);
 $\mapsto x2$ 
 $\mapsto$ 
kill Omega_R,dx,dy,dz;

```

See also: [Section D.15.3.17 \[diffformMul\]](#), page 2346.

D.15.3.19 diffformEqu

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `df == dg; df,dg diffform`

Return: 1, if `df` and `dg` are euqal - 0, otherwise

Example:

```

LIB "diffform.lib";
ring R = 0,(x,y,z),ds;

```

```

diffAlgebra();
↪ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// Applications of comparison operator //
////////////////////////////////////
diffform df = 3*dx - x8*dx*dy;
diffform dg = 3 + x8*dy;
df == dg;
↪ 0
dg = dg*dx;
df == dg;
↪ 1
kill Omega_R,df,dg,dx,dy,dz;

```

See also: [Section D.15.3.20 \[diffformNeq\]](#), page 2348.

D.15.3.20 diffformNeq

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `df != dg; df,dg diffform`

Return: 0, if df and dg are euqal - 1, otherwise

Example:

```

LIB "diffform.lib";
ring R = 0,(x,y,z),ds;
diffAlgebra();
↪ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// Applications of negated comparison operator //
////////////////////////////////////
diffform df = 3*dx - x8*dx*dy;
diffform dg = 3 + x8*dy;
df != dg;
↪ 1
dg = dg*dx;
df != dg;
↪ 0
kill Omega_R,df,dg,dx,dy,dz;

```

See also: [Section D.15.3.19 \[diffformEqu\]](#), page 2347.

D.15.3.21 diffformIsBigger

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `df > dg OR diffformIsBigger(df,dg,#); df,dg diffform, # list`

Return: - 1, if df is bigger than dg with respect to the monomial ordering in the differential algebra - 0, otherwise - 1, if df is bigger than dg with respect to a given monomial ordering on the generators/ringvariables - 0, otherwise

Note: the procedure uses `diffAlgebraChangeOrd` to change the order on the differential algebra, therefore an ordering is defined via the following pattern:

- `#[i] = 'gen'` defines the ordering on the generators `dx_i` - `#[i+1]` must then be a valid monomial ordering as string - `#[i+2]` an optional weight vector
- `#[i] = 'ringvar'` defines the ordering on the ringvariables - `#[i+1]` must then be a valid monomial ordering as string - `#[i+2]` an optional weight vector

Example:

```
LIB "diffform.lib";
ring R = 0,(x,y,z),dp;
diffAlgebra();
⇒ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// With standard ordering //
////////////////////////////////////
dx > dy;
⇒ 1
x37*dy > dz;
⇒ 1
x*dz > y*x*dy;
⇒ 0
x3*dx - y*dx*dz > dx*dy*dz;
⇒ 0
////////////////////////////////////
// With changed ordering //
////////////////////////////////////
diffformIsBigger(dx,dy,"gen","ls");
⇒ 0
diffformIsBigger(x37*dy,dz,"gen","wp",intvec(1,-1,1));
⇒ 0
diffformIsBigger(x*dz,y*x*dy,"gen","wp",intvec(1,-1,1),"ringvar","wp",intvec(1,-1,1));
⇒ 1
diffformIsBigger(x3*dx - y*dx*dz,dx*dy*dz,"gen","wp",intvec(-1,-1,1));
⇒ 1
kill Omega_R,dx,dy,dz;
```

See also: [Section D.15.3.5 \[diffAlgebraChangeOrd\]](#), page 2337; [Section D.15.3.22 \[diffformIsSmaller\]](#), page 2349.

D.15.3.22 diffformIsSmaller

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

- Usage:** `df < dg` OR `diffformIsSmaller(df,dg,#)`; `df,dg` diffform, `#` list
- Return:** - 1, if `df` is smaller than `dg` with respect to the monomial ordering in the differential algebra - 0, otherwise - 1, if `df` is smaller than `dg` with respect to a given monomial ordering on the generators/ringvariables - 0, otherwise
- Note:** the procedure uses `diffAlgebraChangeOrd` to change the order on the differential algebra, therefore an ordering is defined via the following pattern:
- `#[i] = 'gen'` defines the ordering on the generators `dx_i` - `#[i+1]` must then be a valid monomial ordering as string - `#[i+2]` an optional weight vector
 - `#[i] = 'ringvar'` defines the ordering on the ringvariables - `#[i+1]` must then be a valid monomial ordering as string - `#[i+2]` an optional weight vector

Example:

See also: [Section D.15.3.5 \[diffAlgebraChangeOrd\]](#), page 2337; [Section D.15.3.21 \[diffformIsBigger\]](#), page 2348.

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Note:

- the procedure does not check if `df` is homogeneous
- be careful: `diffformDeg` does not cast polynomials to differential forms. So before applying to a polynomial, a type cast should be done

[illegible]

```

deg(3 + x8*dy);
↳ 1
// When applying homog to a polynomial which is considered
// as a differential form, a type cast has to be done first
deg(x2-y);
↳ 2
diffform df = x2-y;
deg(df);
↳ 0
kill Omega_R,df,dx,dy,dz;

```

See also: [Section D.15.3.24 \[diffformIsHomog\]](#), page 2351; [Section D.15.3.25 \[diffformIsHomogDeg\]](#), page 2352.

D.15.3.24 diffformIsHomog

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `homog(df); df diffform`

Return: 1, if df is homogeneous - 0, otherwise

Note: - the form 0 is homogeneous
 - be careful: `diffformIsHomog` does not cast polynomials to differential forms. So before applying to a polynomial, a type cast should be done

Example:

```

LIB "diffform.lib";
ring R = 0,(x,y,z),ds;
diffAlgebra();
↳ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////
// Homogeneous //
////////////////////////////////
homog(3*dx*dz - x8*dx*dy);
↳ 0
homog(12x*dx + dy - (y4-y5)*dz);
↳ 0
////////////////////////////////
// Not homogeneous //
////////////////////////////////
homog(3 + x8*dy);
↳ 0
homog(x*dx+dy*dx);
↳ 0
// When applying homog to a polynomial which is considered
// as a differential form, a type cast has to be done first
homog(3x-y2);
↳ 0
diffform df = 3x-y2;
homog(df);
↳ 1
kill Omega_R,dx,dy,dz,df;

```

See also: [Section D.15.3.23 \[diffformDeg\]](#), page 2350; [Section D.15.3.25 \[diffformIsHomogDeg\]](#), page 2352.

D.15.3.25 diffomIsHomogDeg

Procedure from library `diffom.lib` (see [Section D.15.3 \[diffom.lib\]](#), page 2334).

Usage: `diffomIsHomogDeg(df,p);` df diffom, p int

Return: 1, if df is homogeneous of degree p - 0, otherwise

Note: - 0 is homogeneous of degree -1

Example:

```
LIB "diffom.lib";
ring R = 0,(x,y,z),ds;
diffAlgebra();
⇒ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
diffom df = 3*dx*dz - x8*dx*dy;
diffom dg = 3 + x8*dy;
diffom dh = 2;
diffom dt = 0;
////////////////////////////////////
// Homogeneous of given degree //
////////////////////////////////////
diffomIsHomogDeg(df,2);
⇒ 0
diffomIsHomogDeg(dh,0);
⇒ 1
diffomIsHomogDeg(dt,-1);
⇒ 1
////////////////////////////////////
// Not homogeneous of given degree //
////////////////////////////////////
diffomIsHomogDeg(df,1);
⇒ 0
diffomIsHomogDeg(dg,1);
⇒ 0
diffomIsHomogDeg(dh,1);
⇒ 0
kill Omega_R,df,dg,dh,dt,dx,dy,dz;
```

See also: [Section D.15.3.23 \[diffomDeg\]](#), page 2350; [Section D.15.3.24 \[diffomIsHomog\]](#), page 2351.

D.15.3.26 diffomListCont

Procedure from library `diffom.lib` (see [Section D.15.3 \[diffom.lib\]](#), page 2334).

Usage: `diffomListCont(L,df);` L list, df diffom

Return: 1, if df is in the list L - 0, otherwise

Note: lists with arbitrary input are allowed

Example:

```
LIB "diffom.lib";
ring R = 17,(a,b,c),lp;
diffAlgebra();
⇒ // The differential algebra Omega_R was constructed and the differential \
```

```

    forms dDa, dDb, dDc, da, db, dc are available.
list L = "", 3, 12*a, da-db, 16 + dc, 23*da - 4*db*dc*da, db - 4, "entry", dc - db*da, a
//////////
// Elements in the list //
//////////
difformListCont(L, da - db);
↪ 1
difformListCont(L, 16 + dc);
↪ 1
difformListCont(L, dc - db*da);
↪ 1
//////////
// Elements not in the list //
//////////
difformListCont(L, 22*da);
↪ 0
difformListCont(L, 1);
↪ 0
difformListCont(L, a);
↪ 0
kill Omega_R, L, da, db, dc;

```

See also: [Section D.15.3.19 \[difformEqu\]](#), page 2347.

D.15.3.27 difformListSort

Procedure from library `difform.lib` (see [Section D.15.3 \[difform.lib\]](#), page 2334).

Return: the sorted list L in ascending order, depending on the optional monomial ordering given

Remarks: Classical insertion sort is used to sort the list

Note:

- the procedure uses `difformIsBigger` to compare list elements, therefore an optional ordering is defined via the pattern in `difformIsBigger` - the standard ordering is the ordering on the differential algebra - the procedure can also handle special lists of lists by using the optional input "Dlist" or "Llist":
- "Dlist" is used for lists with structure:
 $L[1]$ is a list of differential forms
 $L[2]$ is a list of polynomials of same size,
The list gets sorted by the elements in $L[1]$. This is mainly used for the structure of derivations.
- "Llist" allows the structure: $L[i]$ is a list with two entries: $L[i][1]$ is a differential form
 $L[i][2]$ is a polynomial
The list gets sorted by the elements $L[i][1]$. This is used to sort coefficient lists.

Example:

```

LIB "difform.lib";
ring R = 0, (x, y, z, t), dp;
diffAlgebra();
↪ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dDt, dx, dy, dz, dt are available.
//////////
// Sortation of a list //
//////////
list L = dx*x, x2 - y*t, 12, dt*dy*dx*dz;

```

```

// Sort list with standard ordering

kill Omega_R,dx,dy,dz,dt,L,DL,LL;

```

See also: [Section D.15.3.21 \[diffformIsBigger\]](#), page 2348; [Section D.15.3.22 \[diffformIsSmaller\]](#), page 2349.

D.15.3.28 diffformUnivDer

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `diffformUnivDer(f); f poly`

Return: a differential form: the image of the universal derivation applied to `f`

Example:

```

LIB "diffform.lib";
ring R = 0,(x,y,z),lp;
diffAlgebra();
⇒ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// Universal derivation applied to polynomials //
////////////////////////////////////
diffformUnivDer(3x);
⇒ 3*dx
⇒
diffformUnivDer(xyz+x2y2z2);

```

```

    ↪ (2xy2z2+yz)*dx+(2x2yz2+xz)*dy+(2x2y2z+xy)*dz
    ↪
    diffformUnivDer(x+y+z);
    ↪ dx+dy+dz
    ↪
    kill Omega_R,dx,dy,dz;

```

See also: [Section D.15.3.29 \[diffformDiff\]](#), page 2356.

D.15.3.29 diffformDiff

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `diffformDiff(df); df diffform`

Return: the image of `df` under the differential

Remark: To compute the image, the universal derivation is applied to each coefficient and multiplied with the corresponding generator

Note: - the differential is a map $\Omega_R^p \rightarrow \Omega_R^{p+1}$ and this procedure applies the differential to all homogeneous parts of `df`
 - this procedure can also be applied to polynomials - in this case it is just the universal derivation

Example:

```

LIB "diffform.lib";
ring R = 0,(x,y,z,a,b,c),lp;
diffAlgebra();
↪ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dDa, dDb, dDc, dx, dy, dz, da, db, dc are available.
////////////////////////////////////
// Construction of differential forms //
////////////////////////////////////
diffform df_1 = y*dx + z*dy + x*dz + a*db + b*dc + c*da;
diffform df_2 = -5*c4*dc*dz*dy + 3*dx*dz - 13*a4*da*db + 12*a4*da*db + x8*dx*dy + 12 -
poly f = 3x2y2 - z3*c;
////////////////////////////////////
// Differential applied to the forms //
////////////////////////////////////
diffformDiff(df_1);
↪ (-1)*dx*dy+dx*dz+(-1)*dy*dz+da*db+(-1)*da*dc+db*dc
↪
diffformDiff(df_2);
↪ (-2x)*dx*dy*db+(5x12y4-4x12y3)*dx*dy*dz*db
↪
diffformDiff(f);
↪ 6xy2*dx+6x2y*dy+(-3z2c)*dz+(-z3)*dc
↪
// The composition of differentials is the zero-map:
diffformDiff(diffformDiff(df_1));
↪ 0
↪
kill Omega_R,df_1,df_2,f,dx,dy,dz,da,db,dc;

```

See also: [Section D.15.3.28 \[diffformUnivDer\]](#), page 2355.

D.15.3.30 derivationFromList

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `derivation phi = derivationFromList(L);` L list

Return: the derivation defined by the list L

Remarks: The structure of L is checked and L is sorted,
then it is set as structure list of phi

Note: the structure of L must follow the rules:
- L[1] is a list of all degree-1 generators: all dx_i must occur once and no other differential forms are allowed. The order of the list is not important - L[2] is the list of images of the dx_i : these must be polynomials Since the map is linear, it is enough to store the images of the dx_i

Example:

```
LIB "diffform.lib";
ring R = 11,(u,v,w,x),lp;
diffAlgebra();
⇨ // The differential algebra Omega_R was constructed and the differential \
    forms dDu, dDv, dDw, dDx, du, dv, dw, dx are available.
////////////////////////////////////
// Construction of structure lists //
////////////////////////////////////
list L_1;
L_1[1] = list(du,dv,dw,dx);
L_1[2] = list(u,v,w,x);
list L_2;
L_2[1] = list(dx,dw,du,dv);
L_2[2] = list(x2,w2,u2,v-wu);
////////////////////////////////////
// Construction of derivations //
////////////////////////////////////
derivation phi = derivationFromList(L_1); phi;
⇨ Omega_R^1 --> R
⇨      du |--> u
⇨      dv |--> v
⇨      dw |--> w
⇨      dx |--> x
⇨
⇨
derivation psi = derivationFromList(L_2); psi;
⇨ Omega_R^1 --> R
⇨      du |--> u2
⇨      dv |--> -uw+v
⇨      dw |--> w2
⇨      dx |--> x2
⇨
⇨
kill Omega_R,du,dv,dw,dx,phi,psi,L_1,L_2;
```

See also: [Section D.15.3.31 \[derivationCheckList\]](#), page 2358; [Section D.15.3.33 \[derivationConstructor\]](#), page 2359; [Section D.15.3.32 \[derivationFromPoly\]](#), page 2358.

D.15.3.31 derivationCheckList

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `derivationCheckList(L);` L list

Remarks: The procedure checks if a given list has the right form for a derivation and throws an error if this is not the case. In particular: - Only degree-1 generators are allowed in `L[1]` - this is checked via `diffformIsGen` - Any degree-1 generator must occur once - this is checked via `diffformListCont`

Note: like in `derivationFromList`, the structure of L must follow the rules: - `L[1]` is a list of all degree-1 generators: all `dx_i` must occur once and no other differential forms are allowed. The order of the list is not important - `L[2]` is the list of images of the `dx_i`: these must be polynomials

See also: [Section D.15.3.30 \[derivationFromList\]](#), page 2357; [Section D.15.3.13 \[diffformIsGen\]](#), page 2344; [Section D.15.3.26 \[diffformListCont\]](#), page 2352.

D.15.3.32 derivationFromPoly

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `derivation phi = derivationFromPoly(f);` f poly

Return: a derivation which maps any degree-1 generator to f

Remarks: The degree-1 generators are returned by `diffAlgebraListGen`

Note: the procedure allows to interpret polynomials as derivations

Example:

```
LIB "diffform.lib";
ring R = 0,(x,y,z),lp;
diffAlgebra();
⇒ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// Construction of derivations from polynomials //
////////////////////////////////////
derivation phi = derivationFromPoly(3x*y - 12*y4-z2); phi;
⇒ Omega_R^1 --> R
⇒      dx |--> 3xy-12y4-z2
⇒      dy |--> 3xy-12y4-z2
⇒      dz |--> 3xy-12y4-z2
⇒
⇒
derivation psi = derivationFromPoly(0); psi;
⇒ Omega_R^1 --> R
⇒      dx |--> 0
⇒      dy |--> 0
⇒      dz |--> 0
⇒
⇒
kill Omega_R,dx,dy,dz,phi,psi;
```

See also: [Section D.15.3.33 \[derivationConstructor\]](#), page 2359; [Section D.15.3.30 \[derivationFromList\]](#), page 2357.

D.15.3.33 derivationConstructor

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `derivation phi = inp; inp` of any type

Return: the derivation defined by `inp`:

Remarks: the output depends on the type of `inp`:
 - if `inp` is of type `list`, the constructor `derivationFromList` is used - if `inp` is of type `poly`,
 number, `int` or `bigint`, `derivationFromPoly` is used

Note: for other than the mentioned types, there is no output

Example:

```
LIB "diffform.lib";
ring R = 31,(x,y,z),dp;
diffAlgebra();
⇨ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// Construction of derivations from lists and polynomials //
////////////////////////////////////
list L; L[1] = list(dx,dz,dy); L[2] = list(x2,y-x,z);
derivation phi = L; phi;
⇨ Omega_R^1 --> R
⇨      dx |--> x2
⇨      dy |--> z
⇨      dz |--> -x+y
⇨
⇨
derivation psi = 3x2-12z; psi;
⇨ Omega_R^1 --> R
⇨      dx |--> 3x2-12z
⇨      dy |--> 3x2-12z
⇨      dz |--> 3x2-12z
⇨
⇨
kill Omega_R,dx,dy,dz,phi,psi;
```

See also: [Section D.15.3.30 \[derivationFromList\]](#), page 2357; [Section D.15.3.32 \[derivationFromPoly\]](#), page 2358.

D.15.3.34 derivationToString

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `derivationToString(phi,#); phi` derivation, `#` list

Return: the derivation as a string, describing the image of the degree-1 generators, optionally ordered by a given monomial ordering on the generators

Remarks: To sort the images of the generators in the output string, `diffformListSort` is used.

Note: to define an ordering for the generators, one can use:

- `#[1] = 'gen'`
 - `#[2]`: a monomial ordering as string
 - `#[3]`: an optional weight vector
- the standard ordering is the ordering of the differential algebra

Example:

```

LIB "diffform.lib";
ring R = 0,(x,y,z),dp;
diffAlgebra();
⇨ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
list L; L[1] = list(dx,dy,dz); L[2] = list(x2,y-23xz,xz4);
derivation phi = L;
////////////////////////////////////
// String with standard ordering //
////////////////////////////////////
print(derivationToString(phi));
⇨ Omega_R^1 --> R
⇨      dz |--> xz4
⇨      dy |--> -23xz+y
⇨      dx |--> x2
⇨
////////////////////////////////////
// String with changed ordering //
////////////////////////////////////
print(derivationToString(phi,"gen","wp",intvec(-1,-1,1)));
⇨ Omega_R^1 --> R
⇨      dy |--> -23xz+y
⇨      dx |--> x2
⇨      dz |--> xz4
⇨
kill Omega_R,dx,dy,dz,L,phi;

```

See also: [Section D.15.3.35 \[derivationPrint\]](#), page 2360; [Section D.15.3.9 \[diffformGenToString\]](#), page 2341; [Section D.15.3.27 \[diffformListSort\]](#), page 2353.

D.15.3.35 derivationPrint

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `phi`; `phi` derivation

Side effects:
 prints the given derivation

Remarks: Prints the string returned by `derivationToString` with a ls-ordering on the generators

Example:

```

LIB "diffform.lib";
ring R = 0,(a,b,c,x,y,z),lp;
diffAlgebra();
⇨ // The differential algebra Omega_R was constructed and the differential \
    forms dDa, dDb, dDc, dDx, dDy, dDz, da, db, dc, dx, dy, dz are available.
////////////////////////////////////
// Derivations //
////////////////////////////////////
list L; L[1] = list(dx,dy,dz,da,db,dc); L[2] = list(1,12x-y,z4aby, 2*b5x,0,xyz-abc);
derivation phi = L;
derivation phi_poly = 3ab - c2*x + z;
////////////////////////////////////

```

```

// Applications of Print //
////////////////////////
phi;
  Omega_R^1 --> R
  da |--> 2b5x
  db |--> 0
  dc |--> -abc+xyz
  dx |--> 1
  dy |--> 12x-y
  dz |--> abyz4
  ↵
  ↵
phi_poly;
  Omega_R^1 --> R
  da |--> 3ab-c2x+z
  db |--> 3ab-c2x+z
  dc |--> 3ab-c2x+z
  dx |--> 3ab-c2x+z
  dy |--> 3ab-c2x+z
  dz |--> 3ab-c2x+z
  ↵
  ↵
kill Omega_R,da,db,dc,dx,dy,dz,L,phi,phi_poly;

```

See also: [Section D.15.3.34 \[derivationToString\]](#), page 2359.

D.15.3.36 derivationAdd

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `phi+psi`; `phi,psi` derivation

Return: the sum of the given derivations

Remark: The sum is computed componentwise - this works since the structure lists of derivations are sorted the same way.

Note: once can also add polynomials and derivations

Example:

```

LIB "diffform.lib";
ring R = 0,(x,y,z),ds;
diffAlgebra();
  ↵ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
list L_1; L_1[1] = list(dx,dy,dz); L_1[2] = list(2x,2y,2z);
list L_2; L_2[1] = list(dx,dy,dz); L_2[2] = list(y2-x,z4+x+y,y2);
////////////////////////
// Derivations //
////////////////////////
derivation phi_1 = L_1; phi_1;
  Omega_R^1 --> R
  dx |--> 2x
  dy |--> 2y
  dz |--> 2z
  ↵

```

```

```

See also: [Section D.15.3.37 \[derivationSub\]](#), page 2362.

D.15.3.37 derivationSub

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: phi-psi; phi,psi derivation

Return: the difference of the given derivations

Remarks: The difference is computed componentwise - this works since the structure lists of derivations are sorted the same way.

Note: one can also subtract polynomials from derivations

Example:

```

LIB "diffform.lib";
ring R = 0,(x,y),lp;
diffAlgebra();
↳ // The differential algebra Omega_R was constructed and the differential \
   forms dDx, dDy, dx, dy are available.
list L_1; L_1[1] = list(dx,dy); L_1[2] = list(x+y,1);

```

```

```

See also: [Section D.15.3.36 \[derivationAdd\]](#), page 2361; [Section D.15.3.38 \[derivationNeg\]](#), page 2363.

D.15.3.38 derivationNeg

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `-phi`; `phi` derivation

Return: the negation of a given derivation

Example:

```

LIB "diffform.lib";
ring R = 0,(x,y,z,t),dp;
diffAlgebra();
  ↳ // The differential algebra Omega_R was constructed and the differential \

```

```

    forms dDx, dDy, dDz, dDt, dx, dy, dz, dt are available.
list L_1; L_1[1] = list(dy,dx,dt,dz); L_1[2] = list(x2-y,23y+t,tz4,z-y);

```

See also: [Section D.15.3.37 \[derivationSub\]](#), page 2362.

D.15.3.39 derivationMul

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `phi*psi`; `phi,psi` derivation

Return: the componentwise product of `phi` and `psi`

Remarks: The product is computed componentwise - this works since the structure lists of derivations are sorted the same way.

Note: one can also multiply polynomials and derivations

Example:

```
LIB "diffform.lib";
ring R = 0,(a,b,t),ls;
diffAlgebra();
⇒ // The differential algebra Omega_R was constructed and the differential \
   forms dDa, dDb, dDt, da, db, dt are available.
list L_1; L_1[1] = list(da,dt,db); L_1[2] = list(2a,2t-b,2t);
list L_2; L_2[1] = list(dt,db,da); L_2[2] = list(-a,-b,-t);
//////////

⇒      da |--> bt2-3a2t
⇒      db |--> b2t-3a2b
⇒      dt |--> abt-3a3
⇒
⇒
kill Omega_R,da,db,dt,L_1,L_2,phi_1,phi_2;

```

D.15.3.40 derivationEqu

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `phi == psi; phi,psi derivation`

Return: 1, if phi and psi are equal - 0, otherwise

Remarks: The images of the generators are compared componentwise - this works since the structure lists of derivations are sorted the same way.

Note: derivations can also be compared to polynomials

Example:

```

LIB "diffform.lib";
ring R = 0,(u,v),lp;
diffAlgebra();
⇒ // The differential algebra Omega_R was constructed and the differential \
   forms dDu, dDv, du, dv are available.
list L_1; L_1[1] = list(dv,du); L_1[2] = list(u,-v);
//////////
// Derivations //
//////////
derivation phi_1 = L_1; phi_1;
⇒ Omega_R^1 --> R
⇒      du |--> -v
⇒      dv |--> u
⇒
⇒
derivation phi_poly = u*v; phi_poly;
⇒ Omega_R^1 --> R
⇒      du |--> uv
⇒      dv |--> uv
⇒
⇒
//////////
// Comparison of derivations //
//////////
phi_1 == phi_1;
⇒ 1
phi_1 == phi_poly;
⇒ 0
phi_poly == u*v;
⇒ 1
kill Omega_R,du,dv,phi_1,phi_poly;

```

See also: [Section D.15.3.41 \[derivationNeq\]](#), page 2367.

D.15.3.41 derivationNeq

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `phi != psi; phi,psi derivation`

Return: 0, if phi and psi are equal - 1, otherwise

Remarks: The comparison is done by `diffformEqu`

Note: derivations can also be compared to polynomials

Example:

```
LIB "diffform.lib";
ring R = 0,(u,v),lp;
diffAlgebra();
⇨ // The differential algebra Omega_R was constructed and the differential \
    forms dDu, dDv, du, dv are available.
list L_1; L_1[1] = list(dv,du); L_1[2] = list(u,-v);
//////////

phi_1 != phi_1;
⇨ 0
phi_1 != phi_poly;
⇨ 1
phi_poly != u*v;
⇨ 0
kill Omega_R,du,dv,phi_1,phi_poly;
```

See also: [Section D.15.3.40 \[derivationEqu\]](#), page 2366.

D.15.3.42 derivationEval

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `phi(df); phi derivation, df diffform`

Return: the polynomial `phi(df)`, the derivation `phi` evaluated at `df`

Remarks: - By linearity it is enough to compute the sum of all differential forms: (coefficient of `dx_i`)*(image of `dx_i`)

- The coefficient list of df is computed via `diffformCoef` - To avoid searching generators in lists, the coefficient list of df and the structure list of ϕ are sorted the same way

Note: - the differential form 0 is allowed as input
 - an error will occur if the given differential form is not of degree 1 or -1

Example:

```
LIB "diffform.lib";
ring R = 13,(x,y,z,t),dp;
diffAlgebra();
⇨ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dDt, dx, dy, dz, dt are available.
////////////////////////////////////
// Construction of derivations //
////////////////////////////////////

    phi_3(dx);
    ↪ 0
    phi_3(dy);
    ↪ 0
    phi_3(dx - 24*(dx + dz) - x4*dy);
    ↪ 0
    kill Omega_R,dx,dy,dz,dt,L_1,L_2,L_3,phi_1,phi_2,phi_3;

```

See also: [Section D.15.3.8 \[diffformCoef\]](#), page 2339; [Section D.15.3.27 \[diffformListSort\]](#), page 2353.

D.15.3.43 derivationContractionGen

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `derivationContractionGen(phi,d_gen);` phi derivation, d_gen diffform

Assume: d_gen is a generator of the differential algebra

Return: the image of d_gen under the contraction map i_phi

Remarks: The formula for the contraction map applied to a generator of degree l is given by:
 $i_{\text{phi}}^l(dx_k \dots dx_j) = \sum_{i=1, \dots, l} (-1)^{i+1} * \text{phi}(dx_i) * (dx_k \dots dx_j / dx_i)$

Note: this procedure should only be applied to generators

See also: [Section D.15.3.44 \[derivationContraction\]](#), page 2369.

D.15.3.44 derivationContraction

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `derivationContraction(phi,df);` phi derivation, df diffform

Return: the image of the contraction map i_phi applied to df

Remarks: Since the contraction map is linear, it is only applied to the generators: So the image of df under i_phi is a sum, where the coefficients are multiplied by the image of the generators.

Note: over the basering, the contraction map is the 0-map

Example:

```

LIB "diffform.lib";
ring R = 0,(x,y,z),lp;
diffAlgebra();
↪ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.
////////////////////////////////////
// Construction of derivations //
////////////////////////////////////
list L_1; L_1[1] = list(dx,dy,dz); L_1[2] = list(x,y,z);
derivation phi_1 = L_1; phi_1;

```

```

    ↪ Omega_R^1 --> R
    ↪      dx |--> x
    ↪      dy |--> y
    ↪      dz |--> z
    ↪
    ↪
    list L_2; L_2[1] = list(dx,dy,dz); L_2[2] = list(y-x,z-y,x-z);
    derivation phi_2 = L_2; phi_2;
    ↪ Omega_R^1 --> R
    ↪      dx |--> -x+y
    ↪      dy |--> -y+z
    ↪      dz |--> x-z
    ↪
    ↪
    //////////////////////////////////////
    // Contractions of derivations //
    //////////////////////////////////////
    derivationContraction(phi_1,dx+dy+dz);
    ↪ x+y+z
    ↪
    derivationContraction(phi_1,x2*y4-z);
    ↪ 0
    ↪
    derivationContraction(phi_1,x2*dx*dy + dx*dy*dz);
    ↪ (-x2y)*dx+(-x3)*dy+z*dx*dy+y*dx*dz+x*dy*dz
    ↪
    derivationContraction(phi_2,dx+dy+dz);
    ↪ 0
    ↪
    derivationContraction(phi_2,dx*dy*dz - dx*dy + dx*dz);
    ↪ (-x-y+2z)*dx+(-x+y)*dy+(x-y)*dz+(x-z)*dx*dy+(-y+z)*dx*dz+(-x+y)*dy*dz
    ↪
    kill Omega_R,dx,dy,dz,L_1,L_2,phi_1,phi_2;

```

See also: [Section D.15.3.44 \[derivationContraction\]](#), page 2369; [Section D.15.3.45 \[derivationLie\]](#), page 2370.

D.15.3.45 derivationLie

Procedure from library `diffform.lib` (see [Section D.15.3 \[diffform.lib\]](#), page 2334).

Usage: `diff(phi,df);` phi derivation, df diffform

Return: the image of df under the Lie-derivative L_{phi}

Remarks: The map L_{phi} is the anticommutator of the contraction map i_{phi} and the differential d :
 $(i_{\text{phi}} \circ d) + (d \circ i_{\text{phi}})$

Example:

```

LIB "diffform.lib";
ring R = 0,(x,y,z),lp;
diffAlgebra();
↪ // The differential algebra Omega_R was constructed and the differential \
    forms dDx, dDy, dDz, dx, dy, dz are available.

```

D.15.4 enumpoints.lib

Library: enumpoints.lib

Purpose: enumerating rational points

Author: Jieao Song (8d1h)

Procedures:

D.15.4.1 points

Procedure from library `enumpoints.lib` (see [Section D.15.4 \[enumpoints.lib\]](#), page 2371).

Usage: `points(I)`; I homogeneous ideal

Return: list of coordinates of points on the zero set of I

Assumes: $\dim(I)=0$

D.15.4.2 projPoints

Procedure from library `enumpoints.lib` (see [Section D.15.4 \[enumpoints.lib\]](#), page 2371).

Return: list of coordinates of points on the zero set of I

Assumes: $\dim(I)=0$

Example:

```
LIB "enumpoints.lib";
// The set of nodes is a 0-dimensional variety over a number field.
ring R2 = (0,q),(x,y,z,w),dp;
minpoly = q16-q12+q8-q4+1;
poly s = 2q13-q9-q7+q5-q3-q;
ideal Togliatti = 64*(x-w)*(x^4 -4*x^3*w -10*x^2*y^2 -4*x^2*w^2 +16*x*w^3 -20*x*y^2*w);
matrix Jac = jacob(Togliatti);
ideal I2 = Togliatti+Jac;
list L=projPoints(std(I2));
L[1];
⇒ [1]:
⇒ 1
⇒ [2]:
⇒ 0
⇒ [3]:
⇒ (1/2q13-1/4q9-1/4q7+1/4q5-1/4q3-1/4q)
⇒ [4]:
⇒ (-q12+q8+3/2)
size(L);
⇒ 31
```

D.15.5 finitediff.lib

Issues:

- installation of `qepcadfilter.pl` needs to be solved
- tests for (nearly) all procedures are missing
- global variables needs to be cleaned
- temporary files needs to be cleaned
- temporary file names need to be unique (think about multiple instances)
- pollution of global Top namespace must be solved
- `u` is not a good name for a procedure

Library: `finitediff.lib`

Purpose: procedures to compute finite difference schemes for linear differential equations

Author: Christian Dingler

Overview: Using `qepcad/qepcadsystem` from this library requires the program `qepcad` to be installed. You can download `qepcad` from <http://www.usna.edu/CS/qepcadweb/B/QEPCAD.html>

Procedures:

D.15.5.1 visualize

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `visualize(f)`; `f` of type `poly`.

Return: type string; translates the polynomial form of a finite difference scheme into an indexed one as often seen in literature

Example:

```
LIB "finitediff.lib";
list D="Ux","Ut","U";
list P="a";
list V="t","x";
setinitials(V,D,P);
scheme(u(Ut)+a*u(Ux),trapezoid(Ux,U,x),backward(Ut,U,t));
 $\mapsto$  (dx)*x+(dx)
visualize(_);
 $\mapsto$  (dx)*U(0,1)+(dx)*U(0,0)
```

D.15.5.2 u

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `u(D[,#])`; `D` a string that occurs in the list of `@derivatives`, `#` an optional list of integers.

Return: type vector; gives the vector, that corresponds with $\text{gen}(n)^*m$, where `m` is the monomial defined by `#`

Example:

```
LIB "finitediff.lib";
list D="Ux","Uy","Ut","U";
list P="a","b";
list V="t","x","y";
setinitials(V,D,P);
u(Ux);
 $\mapsto$  [1]
u(Ux,2,3,7);
 $\mapsto$  [t^2*x^3*y^7]
u(Uy)+u(Ut)-u(Ux);
 $\mapsto$  [-1,1,1]
u(U)*234-dx*dt*dy*3*u(Uy);
 $\mapsto$  [0,(-3*dt*dx*dy),0,234]
```

D.15.5.3 scheme

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `scheme([v1,...,vn])`; `v1,...,vn` of type vector

Return: poly

Purpose: performs substitutions by the means of Groebner basis computation of the submodule, generated by the input vectors, then intersects the intermediate result with the suitable component in order to get a finite difference scheme

Note: works only for a single PDE, for the case of a system use `matrixsystem`

Example:

```
LIB "finitediff.lib";
list D="Ux","Ut","U";
list P="a";
list V="t","x";
setinitials(V,D,P);
def s1=scheme(u(Ut)+a*u(Ux),backward(Ux,U,x),forward(Ut,U,t));
s1;
 $\mapsto (-a*dt+dx)/(dx)*x+(a*dt)/(dx)$ 
```

D.15.5.4 laxfrT

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\], page 2372](#)).

Usage: `laxfrT(U1,U2,var)`; U1, U2 are the names of occurring derivatives, var is a variable in the basering;

Return: type vector; gives a predefined approximation of the Lax-Friedrich-approximation for the derivation in the timevariable as often used in literature;

Note: see also `laxfrX`, `setinitials`, `scheme`; Warning: `laxfrT` is not to be interchanged with `laxfrX`

Example:

```
LIB "finitediff.lib";
list D="Ux","Ut","U";
list P="a";
list V="t","x";
setinitials(V,D,P);
laxfrT(Ux,U,x);
 $\mapsto [(dt)*x,0,-t*x+1/2*x^2+1/2]$ 
```

D.15.5.5 laxfrX

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\], page 2372](#)).

Usage: `laxfrX(U1,U2,var)`; U1, U2 are the names of occurring derivatives, var is a variable in the basering;

Return: type vector; gives a predefined approximation of the Lax-Friedrich-approximation for the derivation in one of the spatial variables as often used in literature;

Note: see also `laxfrT`, `setinitials`, `scheme`; Warning: `laxfrX` is not to be interchanged with `laxfrT`

Example:

```
LIB "finitediff.lib";
list D="Ux","Ut","U";
list P="a";
```

```
list V="t","x";
setinitials(V,D,P);
laxfrX(Ux,U,x);
↦ [(2*dx)*x,0,-x^2+1]
```

D.15.5.6 forward

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `forward(U1,U2,var)`; U1, U2 are the names of occuring derivatives, var is a variable in the basering;

Return: type vector; gives a predefined approximation of the forward approximation as often used in literature;

Note: see also `laxfrT`, `setinitials`, `scheme`;

Example:

```
LIB "finitediff.lib";
list D="Ut","Ux","Uy","U";
list V="t","x","y";
list P="a","b";
setinitials(V,D,P);
forward(Ux,U,x);
↦ [0,(dx),0,-x+1]
forward(Uy,U,y);
↦ [0,0,(dy),-y+1]
forward(Ut,U,t);
↦ [(dt),0,0,-t+1]
```

D.15.5.7 backward

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `backward(U1,U2,var)`; U1, U2 are the names of occuring derivatives, var is a variable in the basering;

Return: type vector; gives a predefined approximation of the backward approximation as often used in literature;

Note: see also `forward`, `laxfrT`, `setinitials`, `scheme`;

Example:

```
LIB "finitediff.lib";
list D="Ut","Ux","Uy","U";
list V="t","x","y";
list P="a","b";
setinitials(V,D,P);
backward(Ux,U,x);
↦ [0,(dx)*x,0,-x+1]
backward(Uy,U,y);
↦ [0,0,(dy)*y,-y+1]
backward(Ut,U,t);
↦ [(dt)*t,0,0,-t+1]
```

D.15.5.8 central1st

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `central1st(U1,U2,var)`; U1, U2 are the names of occuring derivatives, var is a variable in the basering;

Return: type vector; gives a predefined approximation of the first-order-central-approximation as often used in literature;

Note: see also `forward`, `laxfrT`, `setinitials`, `scheme`;

Example:

```
LIB "finitediff.lib";
list D="Ut","Ux","Uy","U";
list V="t","x","y";
list P="a","b";
setinitials(V,D,P);
central1st(Ux,U,x);
↦ [0,(2*dx)*x,0,-x^2+1]
central1st(Uy,U,y);
↦ [0,0,(2*dy)*y,-y^2+1]
```

D.15.5.9 central2nd

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `central2nd(U1,U2,var)`; U1, U2 are the names of occuring derivatives, var is a variable in the basering;

Return: type vector; gives a predefined approximation of the second-order-central-approximation as often used in literature;

Note: see also `forward`, `laxfrT`, `setinitials`, `scheme`;

Example:

```
LIB "finitediff.lib";
list D="Uxx","Ux","Utt","Ut","U";
list P="lambda";
list V="t","x";
setinitials(V,D,P);
central2nd(Uxx,U,x);
↦ [(dx^2)*x,0,0,0,-x^2+2*x-1]
central2nd(Utt,U,t);
↦ [0,0,(dt^2)*t,0,-t^2+2*t-1]
```

D.15.5.10 trapezoid

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `trapezoid(U1,U2,var)`; U1, U2 are the names of occuring derivatives, var is a variable in the basering;

Return: type vector; gives a predefined approximation of the trapezoid-approximation as often used in literature;

Note: see also `forward`, `laxfrT`, `setinitials`, `scheme`;

Example:

```

LIB "finitediff.lib";
list D="Uxx","Ux","Utt","Ut","U";
list P="lambda";
list V="t","x";
setinitials(V,D,P);
trapezoid(Uxx,Ux,x);
 $\mapsto [(dx)/2*x+(dx)/2,-x+1]$ 
trapezoid(Ux,U,x);
 $\mapsto [0,(dx)/2*x+(dx)/2,0,0,-x+1]$ 

```

D.15.5.11 midpoint

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `midpoint(U1,U2,var)`; U1, U2 are the names of occuring derivatives, var is a variable in the basering;

Return: type vector; gives a predefined approximation of the midpoint-approximation as often used in literature;

Note: see also `forward,laxfrT,setinitials,scheme`;

Example:

```

LIB "finitediff.lib";
list D="Uxx","Ux","Utt","Ut","U";
list P="lambda";
list V="t","x";
setinitials(V,D,P);
midpoint(Ux,U,x);
 $\mapsto [0,(2*dx)*x,0,0,-x^2+1]$ 

```

D.15.5.12 pyramid

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `pyramid(U1,U2,var)`; U1, U2 are the names of occuring derivatives, var is a variable in the basering;

Return: type vector; gives a predefined approximation of the pyramid-approximation as often used in literature;

Note: see also `forward,laxfrT,setinitials,scheme`;

Example:

```

LIB "finitediff.lib";
list D="Uxx","Ux","Utt","Ut","U";
list P="lambda";
list V="t","x";
setinitials(V,D,P);
pyramid(Ux,U,x);
 $\mapsto [0,(dx)/3*x^2+(dx)/3*x+(dx)/3,0,0,-x^3+x]$ 

```

D.15.5.13 setinitials

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `setinitials(V,D[,P]);` V,D,P are lists with strings as elements

Return: no return value: sets the dependence order of the occurring derivatives, constructs the suitable ring to compute in containing user chosen parameters, sets new basering

Note: P is optional, used to introduce some additional parameters into the ring. The Sine and Cosine values needed for the fourier transformation are symbolically introduced under the names `string(c)+nameof(variable)`, i.e. if x is any spatial variable then `cx:=cosine(dx*ksi)`, when regarding the fourier transform after ksi (for sine respectively). Artificial parameters I,T,Px,Py are introduced for the later eigenvalue analysis. Variables can be transformed into parameters of similar name

Example:

```
LIB "finitediff.lib";
list D="Ut","Ux","Uy","U";
list V="t","x","y";
list P="alpha","beta","gamma";
setinitials(V,D,P);////does not show the ring, since there is no output
basing;////does show the ring
⇒ // coefficients: QQ(I, T, Px, Py, Cx, Cy, Sx, Sy, alpha, beta, gamma, dt,\
    dx, dy)
⇒ // number of vars : 8
⇒ //          block  1 : ordering c
⇒ //          block  2 : ordering lp
⇒ //          : names    i t x y cx cy sx sy
⇒ // quotient ring from ideal
⇒ _[1]=cy^2+sy^2-1
⇒ _[2]=cx^2+sx^2-1
⇒ _[3]=i^2+1
```

D.15.5.14 errormap

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `errormap(f);` f of type poly

Return: type poly; performs the fouriertransformation of a single polynomial

Example:

```
LIB "finitediff.lib";
list D="Ux","Ut","U";
list P="a";
list V="t","x";
setinitials(V,D,P);
scheme(u(Ut)+a*u(Ux),central1st(Ux,U,x),backward(Ut,U,t));
⇒ (2*dx)*x
errormap(_);
⇒ (2*dx)*i*sx+(2*dx)*cx
```

D.15.5.15 matrixsystem

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `matrixsystem(M,A)`; where the $M=M_t, M_1, \dots, M_n$ is a list with square matrices of the same dimension as entries, and $A=A_t, A_1, \dots, A_n$ gives the corresponding approximations for the several variables (t, x_1, \dots, x_n) as vector. Intended to solve $M_t \cdot U_t + M_1 \cdot U_{x_1} + \dots + M_n \cdot U_{x_n} = 0$ as a linear system of partial differential equations numerically by a finite difference scheme;

Return: type matrix; gives back the matrices B_1, B_2 that represent the finite difference scheme, partitioned into different time levels in the form: $B_1 \cdot U(t=N) = B_2 \cdot U(t < N)$, where N is the maximal occurring degree (timelevel) of t .

Example:

```
LIB "finitediff.lib";
list D="Ut","Ux","Uy","U";
list V="t","x","y";
list P="a","b";
setinitials(V,D,P);
list Mat=unitmat(2),unitmat(2);
list Appr=forward(Ut,U,t),forward(Ux,U,x);
matrixsystem(Mat,Appr);
⇒ _[1,1]=-1/(dt)*t-1/(dx)*x+(dt+dx)/(dt*dx)
⇒ _[1,2]=0
⇒ _[2,1]=0
⇒ _[2,2]=-1/(dt)*t-1/(dx)*x+(dt+dx)/(dt*dx)
```

D.15.5.16 timestep

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `timestep(M)`; M a square matrix with polynomials over the basering as entries;

Return: type list; gives two matrices M_1, M_2 that are the splitting of M with respect to the degree of the variable t in the entries, where the first list-entry M_1 consists of the polynomials of the highest timelevel and M_2 of the lower levels in the form: $M=0 \Rightarrow M_1=M_2$, i.e. $M_1-M_2=M$

Note: intended to be used for the finite-difference-scheme-construction and partition into the several time steps

Example:

```
LIB "finitediff.lib";
list D="Ut","Ux","Uy","U";
list V="t","x","y";
list P="a","b";
setinitials(V,D,P);
list Mat=unitmat(2),unitmat(2);
list Apr=forward(Ut,U,t),forward(Ux,U,x);
matrixsystem(Mat,Apr);
⇒ _[1,1]=-1/(dt)*t-1/(dx)*x+(dt+dx)/(dt*dx)
⇒ _[1,2]=0
⇒ _[2,1]=0
⇒ _[2,2]=-1/(dt)*t-1/(dx)*x+(dt+dx)/(dt*dx)
timestep(_);
```

```

⇒ [1]:
⇒   _[1,1]=t
⇒   _[1,2]=0
⇒   _[2,1]=0
⇒   _[2,2]=t
⇒ [2]:
⇒   _[1,1]=(-dt)/(dx)*x+(dt+dx)/(dx)
⇒   _[1,2]=0
⇒   _[2,1]=0
⇒   _[2,2]=(-dt)/(dx)*x+(dt+dx)/(dx)

```

D.15.5.17 fouriersystem

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `fouriersystem(M,A)`; M a list of matrices, A a list of approximations;

Return: type list; each entry is some matrix obtained by performing the substitution of the single approximations into the system of pde's, partitioning the equation into the several timesteps and fouriertransforming these parts

Example:

```

LIB "finitediff.lib";
list D="Ut","Ux","Uy","U";
list V="t","x","y";
list P="a","b";
setinitials(V,D,P);
matrix M[2][2]=0,-a,-a,0;
list Mat=unitmat(2),M;
list Appr=forward(Ut,U,t),trapezoid(Ux,U,x);
def s=fouriersystem(Mat,Appr);s;
⇒ [1]:
⇒   [1]:
⇒   [1]:
⇒   _[1,1]=(I*T*Sx+T*Cx)
⇒   _[1,2]=0
⇒   _[2,1]=0
⇒   _[2,2]=(I*T*Sx+T*Cx)
⇒   [2]:
⇒   _[1,1]=(I*Sx+Cx)
⇒   _[1,2]=(2*I*Sx*a*dt+2*Cx*a*dt-2*a*dt)/(dx)
⇒   _[2,1]=(2*I*Sx*a*dt+2*Cx*a*dt-2*a*dt)/(dx)
⇒   _[2,2]=(I*Sx+Cx)
⇒   [2]:
⇒   [1]:
⇒   _[1]=(I*T*Sx+T*Cx)
⇒   [2]:
⇒   _[1]=(-2*I*Sx*a*dt+I*Sx*dx-2*Cx*a*dt+Cx*dx+2*a*dt)/(dx)
⇒   _[2]=(2*I*Sx*a*dt+I*Sx*dx+2*Cx*a*dt+Cx*dx-2*a*dt)/(dx)
⇒ [2]:
⇒   [1]:
⇒   [1]:
⇒   (T^2)
⇒   [2]:

```

```

⇒      [1]:
⇒      (-8*Cx*a^2*dt^2+4*Cx*a*dt*dx+8*a^2*dt^2-4*a*dt*dx+dx^2)/(dx^2)
⇒      [2]:
⇒      (-8*Cx*a^2*dt^2-4*Cx*a*dt*dx+8*a^2*dt^2+4*a*dt*dx+dx^2)/(dx^2)

```

D.15.5.18 PartitionVar

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: PartitionVar(f); f a poly in the basering;

Return: type poly; gives back a list L=f1,f2 obtained by the partition of f into two parts f1,f2 with $\deg_var_n(f1) > 0$ $\deg_var_n(f2)=0$

Example:

```

LIB "finitediff.lib";
list D="Ut","Ux","Uy","U";
list V="t","x","y";
list P="a","b";
setinitials(V,D,P);////does not show the ring, since there is no output
basing;////does show the ring
⇒ // coefficients: QQ(I, T, Px, Py, Cx, Cy, Sx, Sy, a, b, dt, dx, dy)
⇒ // number of vars : 8
⇒ //      block 1 : ordering c
⇒ //      block 2 : ordering lp
⇒ //      : names      i t x y cx cy sx sy
⇒ // quotient ring from ideal
⇒ _[1]=cy^2+sy^2-1
⇒ _[2]=cx^2+sx^2-1
⇒ _[3]=i^2+1
poly f=t**3*cx**2-cy**2*dt+i**3*sx;
PartitionVar(f,1); ////i is the first variable
⇒ [1]:
⇒      i^3*sx
⇒ [2]:
⇒      t^3*cx^2+(-dt)*cy^2

```

D.15.5.19 ComplexValue

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: ComplexValue(f); f a poly in the basering;

Return: type poly; gives back the formal complex-value of f, where `var(1)` is redarded as the imaginary unit. Does only make sense, if the proc `<setinitials>` is executed before `-> nvars <= npars`

Example:

```

LIB "finitediff.lib";
list D="Ut","Ux","Uy","U";
list V="t","x","y";
list P="a","b";
setinitials(V,D,P);////does not show the ring, as there is no output
basing;////does show the ring
⇒ // coefficients: QQ(I, T, Px, Py, Cx, Cy, Sx, Sy, a, b, dt, dx, dy)

```

```

⇒ // number of vars : 8
⇒ //          block 1 : ordering c
⇒ //          block 2 : ordering lp
⇒ //          : names      i t x y cx cy sx sy
⇒ // quotient ring from ideal
⇒ _[1]=cy^2+sy^2-1
⇒ _[2]=cx^2+sx^2-1
⇒ _[3]=i^2+1
poly f=t**3*cx**2-cy**2*dt+i**3*sx;
f;
⇒ i^3*sx+t^3*cx^2+(-dt)*cy^2
ComplexValue(f);
⇒ t^6*sx^4-2*t^6*sx^2+t^6+(-2*dt)*t^3*sx^2*sy^2+(2*dt)*t^3*sx^2*sy^2+(-2*dt)*t^3*sx^2+(dt^2)*sy^4+(-2*dt^2)*sy^2+(dt^2)

```

D.15.5.20 VarToPar

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: VarToPar(f); f a poly in the basering;

Return: type poly; gives back the poly obtained by substituting `var(i)` by `par(i)`, for all variables. Does only make sense, if the proc `<setinitials>` is executed before `-> nvars <= npars`;

Example:

```

LIB "finitediff.lib";
list D="Ut","Ux","Uy","U";
list V="t","x","y";
list P="a","b";
setinitials(V,D,P);////does not show the ring, as there is no output
basing;////does show the ring
⇒ // coefficients: QQ(I, T, Px, Py, Cx, Cy, Sx, Sy, a, b, dt, dx, dy)
⇒ // number of vars : 8
⇒ //          block 1 : ordering c
⇒ //          block 2 : ordering lp
⇒ //          : names      i t x y cx cy sx sy
⇒ // quotient ring from ideal
⇒ _[1]=cy^2+sy^2-1
⇒ _[2]=cx^2+sx^2-1
⇒ _[3]=i^2+1
poly f=t**3*cx**2-cy**2*dt+i**3*sx;
f;
⇒ i^3*sx+t^3*cx^2+(-dt)*cy^2
VarToPar(f);
⇒ (I^3*Sx+T^3*Cx^2-Cy^2*dt)

```

D.15.5.21 ParToVar

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: ParToVar(f); f a poly in the basering;

Return: type poly; gives back the poly obtained by substituting `par(i)` by `var(i)`, for the first `nvars(basing parameters)`. Does only make sense, if `setinitials` is executed before `-> nvars <= npars`. Is the opposite action to `VarToPar`, see example `ParToVar`;

Example:

```

LIB "finitediff.lib";
list D="Ut","Ux","Uy","U";
list V="t","x","y";
list P="a","b";
setinitials(V,D,P);////does not show the ring, as there is no output
basing;////does show the ring
⇒ // coefficients: QQ(I, T, Px, Py, Cx, Cy, Sx, Sy, a, b, dt, dx, dy)
⇒ // number of vars : 8
⇒ //          block 1 : ordering c
⇒ //          block 2 : ordering lp
⇒ //          : names      i t x y cx cy sx sy
⇒ // quotient ring from ideal
⇒ _[1]=cy^2+sy^2-1
⇒ _[2]=cx^2+sx^2-1
⇒ _[3]=i^2+1
poly f=t**3*cx**2-cy**2*dt+i**3*sx/dt*dx;
f;
⇒ (dx)/(dt)*i^3*sx+t^3*cx^2+(-dt)*cy^2
def g=VarToPar(f);
g;
⇒ (I^3*Sx*dx+T^3*Cx^2*dt-Cy^2*dt^2)/(dt)
def h=ParToVar(g);
h==f;
⇒ 1

```

D.15.5.22 qepcad

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `qepcad(f)`; f a poly in the basering;

Return: type list; gives back some constraints that are equivalent to $f < 1$ (computed by QEP-CAD);

Example:

```

LIB "finitediff.lib";
list D="Ux","Ut","U";
list P="a";
list V="t","x";
setinitials(V,D,P);
def s1=scheme(u(Ut)+a*u(Ux),laxfrX(Ux,U,x),laxfrT(Ut,U,x));
s1;
⇒ (-a*dt+dx)/(2*dx)*x^2+(a*dt+dx)/(2*dx)
def s2=errormap(s1);
s2;
⇒ (-a*dt+dx)/(dx)*i*cx*sx+(a*dt-dx)/(dx)*sx^2+1
def s3=ComplexValue(s2);s3;
⇒ (a^2*dt^2-dx^2)/(dx^2)*sx^2+1
qepcad(s3);
⇒ 0
⇒ 0
⇒ 0
⇒ sh: qepcad: Kommando nicht gefunden.

```

```

⇒ sh: qepcadfilter.pl: Kommando nicht gefunden.
⇒ 32512
⇒
⇒ Try manually

```

D.15.5.23 qepcadsystem

Procedure from library `finitediff.lib` (see [Section D.15.5 \[finitediff.lib\]](#), page 2372).

Usage: `qepcadsystem(f); l` a list;

Return: list

Purpose: gives back some constraints that are equivalent to the eigenvalues of the matrices in the list `l` being < 1 (computed by QEPCAD)

Example:

```

LIB "finitediff.lib";
list D="Ut","Ux","Uy","U";
list V="t","x","y";
list P="a","b";
setinitials(V,D,P);
matrix M[2][2]=0,-a,-a,0;
list Mat=unitmat(2),M;
list Appr=forward(Ut,U,t),forward(Ux,U,x);
//matrixsystem(Mat,Appr);
//timestep(_);
fourierysystem(Mat,Appr);
⇒ [1]:
⇒   [1]:
⇒     [1]:
⇒       _[1,1]=(T)
⇒       _[1,2]=0
⇒       _[2,1]=0

D.15.6 GND_lib

Library : GND.lib

Author : Adrian Popescu, popescu@mathematik.uni-kl.de

Overview :

A method to compute the General Neron Desingularization in the frame of one dimensional local domains

References:

[1] A. Popescu, D. Popescu, "A method to compute the General Neron Desingularization in the frame of one dimensional local domains", arxiv.org/abs/1508.05511

Procedures:

D.15.6.1 desingularization

Procedure from library GND.lib (see [Section D.15.6 \[GND_lib\]](#), page 2385).

Usage : Returns as output a General Neron Desingularization as in the Paper <http://arxiv.org/abs/1508.05511>

Example:

```

LIB "GND.lib";
//Example 1
ring All = 0, (a1,a2,a3,x1,x2,x3,Y1,Y2,Y3), dp;
int nra = 3;
int nrx = 3;
int nry = 3;
ideal xid = x2^3-x3^2,x1^3-x3^2;
ideal yid = Y1^3-Y2^3;
ideal aid = a3^2-a1*a2;
poly y;
int i;
for(i=0;i<=30;i++)
{
y = y + a1*x3^i/factorial(i);
}
for(i=31;i<=50;i++)
{
y = y + a2*x3^i/factorial(i);
}

```

```

```

D.15.7 gradedModules.lib

Library: gradedModules.lib

Purpose: Operations with graded modules/matrices/resolutions

Authors: Oleksandr Motsak <U@D>, where U=motsak, D=mathematik.uni-kl.de
Hanieh Keneshlou <hkeneshlou@yahoo.com>

Overview: The library contains several procedures for constructing and manipulating graded modules/matrices/resolutions. Basics about graded objects can be found in [DL]. Throughout this library graded objects are graded maps, that is, matrices with polynomials, together with grading weights for source and destination. Graded modules are implicitly given as coker of a graded map. Note that in special cases we may also consider submodules in S^r generated by columns of a graded polynomial matrix (or a graded map).

Note: set `assumeLevel` to positive integer value in order to auto-check all assumptions. We denote the current basering by S .

References:

[DL] Decker, W., Lossen, Ch.: Computing in Algebraic Geometry, Springer, 2006

Procedures:

D.15.7.1 grobj

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), [page 2388](#)).

Usage: `grobj(M, w[, d])`, matrix/ideal/module M , intvec w , d

Return: graded object with matrix presentation M , row weighting w [and total graded degrees d of columns]

Purpose: create a valid graded object with a given matrix presentation, weighting [and total graded degrees (in case of zero columns)]

Example:

```
LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
def A = grobj( module([x+y, x, 0, 0], [0, x+y, y, 0]), intvec(0,0,0,1) );
grview(A);
⇒ Graded homomorphism:  $r^3 + r(-1) \leftarrow r(-1)^2$ , given by a matrix, with degrees:
⇒      ..1 ..2 ....
⇒      --- --- +...
⇒  0 :  1   - |..1
⇒  0 :  1   1 |..2
⇒  0 :  -   1 |..3

⇒ Graded homomorphism: 0 <- 0, given by zero (0^2) matrix.

```

D.15.7.2 grtest

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grtest(M[b])`, anything M, optionally int b

Return: 1 if M is a valid graded object, 0 otherwise

Purpose: validate a graded object. Print an invalid object message if b is not given

Note: M should be an ideal or module or matrix, with weighting attribute 'isHomog' and optionally total graded degrees attribute 'degHomog'. Attributes should be compatible with the presentation matrix.

Example:

```
LIB "gradedModules.lib";
```

```

ring r=32003,(x,y,z),dp;
// the following calls will fail due to tests in grtest:
grobj( module([x+y, x, 0, 0], [0, x+y, y, 0]), intvec(0,0,0,0) ); // enough row weights
⇒ _[1]=x*gen(2)+x*gen(1)+y*gen(1)
⇒ _[2]=x*gen(2)+y*gen(3)+y*gen(2)
// grobj( module([x+y, x, 0, 0], [0, x+y, y, 0]), intvec(0,0) ); // not enough row weights
// grobj( module([x,0], [0,0,0], [0, y]), intvec(1,2,3) ); // zero column needs other weights
grobj( module([x,0], [0,0,0], [0, y]), intvec(1,2,3), intvec(2, 10, 3) ); // compatible
⇒ _[1]=x*gen(1)
⇒ _[2]=0
⇒ _[3]=y*gen(2)
// grobj( module([x,0], [0,0,0], [0, y]), intvec(1,2,3), intvec(2-1, 10, 3+1) ); // compatible

```

D.15.7.3 grdeg

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grdeg(M)`, graded object `M`

Return: `intvec` of degrees

Purpose: graded degrees of columns (generators) of `M`, describing the source of `M`

Assume: `M` must be a graded object (matrix/module/ideal/mapping)

Note: if `M` has zero cols it should have `attrib(M,'degHomog')` set.

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
module A = grobj( module([x+y, x, 0, 0], [0, x+y, y, 0]), intvec(0,0,0,1) );
grview(A);
⇒ Graded homomorphism:  $r^3 + r(-1) \leftarrow r(-1)^2$ , given by a matrix, with degrees:
⇒
  ..1 ..2 ....
  --- --- +...

```

D.15.7.4 grview

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grview(M)`, graded object `M`

Return: nothing

Purpose: print the degree/grading data about the GRADED matrix/module/ideal/mapping object `M`

Assume: `M` must be graded

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
module A = grobj( module([x+y, x, 0, 0], [0,x+y, y, 0]), intvec(0,0,0,1) );
grview(A);

```

D.15.7.5 grshift

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grshift(A, d)`, graded objects A, int d

Return: shifted graded object

Purpose: shift the grading on A by d: $A(i) \rightarrow A(i+d)$

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
module A = grobj( module([x+y, x, 0, 0], [0, x+y, y, 0]), intvec(0,0,0,1) );
grview(A);
⇒ Graded homomorphism: r^3 + r(-1) <- r(-1)^2, given by a matrix, with degrees:
⇒      ..1 ..2 ....
⇒      --- --- +...
⇒ 0 :  1   - |..1
⇒ 0 :  1   1 |..2
⇒ 0 :  -   1 |..3
⇒ 1 :  -   - |..4

```

```

↳      === ===
↳      1 1
module S = grshift( A, 6);
grview(S);
↳ Graded homomorphism:  $r(6)^3 + r(5) \leftarrow r(5)^2$ , given by a matrix, with deg\
rees:
↳      ..1 ..2 ....
↳      --- --- +...
↳ -6 : 1 - |..1
↳ -6 : 1 1 |..2
↳ -6 : - 1 |..3
↳ -5 : - - |..4
↳      === ===
↳      -5 -5
grview( grshift( grzero(), 100 ) ); // does nothing...
↳ !! Warning: shifting '0 <- 0' leaves it as it unchanged!
↳ Graded homomorphism:  $0 \leftarrow 0$ , given by zero ( $0^2$ ) matrix.

```

D.15.7.6 grzero

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grzero()`

Return: graded object representing $S(0)^1$

Purpose: compute presentation of $S(0)^1$

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
grview( grobj(freemodule(0), intvec(0:0), intvec(0:0)) );
↳ Graded homomorphism:  $0 \leftarrow 0$ , given by zero ( $0^2$ ) matrix.
grview( grobj(freemodule(0), intvec(0:0)) );
↳ Graded homomorphism:  $0 \leftarrow 0$ , given by zero ( $0^2$ ) matrix.
grview( grzero() );
↳ Graded homomorphism:  $0 \leftarrow 0$ , given by zero ( $0^2$ ) matrix.
// def M = grpower( grshift( grzero(), 3), 2 ); grview(M);

```

D.15.7.7 grtwist

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grtwist(a,d)`, int a, d

Return: graded object representing $S(d)^a$

Purpose: compute presentation of $S(d)^a$

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
// grview(grpower( grshift(grzero(), 10), 5 ) );
grview( grtwist (5, 10) );
↳ Graded homomorphism:  $r(10)^5 \leftarrow 0$ , given by zero (5 x 0) matrix.

```

D.15.7.8 grtwists

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\], page 2388](#)).

Usage: `grtwists(v), intvec v`

Return: graded object representing $S(v[1]) + \dots + S(v[\text{size}(v)])$

Purpose: compute presentation of $S(v[1]) + \dots + S(v[\text{size}(v)])$

Example:

```
LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
grview( grtwists ( intvec(-4, 1, 6 )) );
⇒ Graded homomorphism: r(-4) + r(1) + r(6) <- 0, given by zero (3 x 0) matr\
ix.
grview( grtwists ( intvec(0:0) ) );
⇒ Graded homomorphism: 0 <- 0, given by zero (0^2) matrix.
```

D.15.7.9 grsum

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\], page 2388](#)).

Usage: `grsum(A, B)`, graded objects A and B

Return: graded direct sum of input objects

Purpose: compute the graded direct sum of A and B

Example:

```
LIB "gradedModules.lib";
// if( defined(assumeLevel) ){ int assumeLevel0 = assumeLevel; } else { int assumeL
ring r=32003,(x,y,z),dp;
module A = grobj( module([x+y, x, 0, 0], [0, x+y, y, 0]), intvec(0,0,0,1) );
grview(A);
⇒ Graded homomorphism: r^3 + r(-1) <- r(-1)^2, given by a matrix, with degr\
ees:
⇒      ..1 ..2 ....
⇒      --- --- +...
⇒  0 :  1   - |..1
⇒  0 :  1   1 |..2

D.15.7.10 grpowers

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grpowers(A, p)`, graded object A, int $p > 0$

Return: graded direct power A^p

Purpose: compute the graded direct power A^p

Note: the power p must be positive

Example:

```
LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
module A = grobj( module([x+y, x, 0], [0, x+y, y]), intvec(1,1,1) );
grview(A);
⇒ Graded homomorphism: r(-1)^3 <- r(-2)^2, given by a matrix, with degrees:
⇒      ..1 ..2 ....
⇒      --- --- +...
⇒      1 :  1  - |..1
⇒      1 :  1  1 |..2
⇒      1 :  -  1 |..3
⇒      === ===
⇒      2    2
module B = grobj( module([x,y]), intvec(2,2) );

```

D.15.7.11 grtranspose

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grtranspose(M)`, graded object `M`

Return: graded object

Purpose: graded transpose of `M`

Note: no reordering is performed by this procedure

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
module M = grtwists( intvec(-2, 0, 4, 4) ); grview(M);
⇒ Graded homomorphism: r(-2) + r + r(4)^2 <- 0, given by zero (4 x 0) matrix.
module N = grsyz( grtranspose( M ) ); grview(N);
⇒ Graded homomorphism: r(2) + r + r(-4)^2 <- r(2) + r + r(-4)^2, given by a\
diagonal matrix, with degrees:
⇒ ..1 ..2 ..3 ..4 ....
⇒ --- --- --- --- +...
⇒ -2 : 0 - - - |..1
⇒ 0 : - 0 - - |..2
⇒ 4 : - - 0 - |..3
⇒ 4 : - - - 0 |..4
⇒      === === === ===
⇒      -2 0 4 4
module L = grtranspose(N); grview( L );
⇒ Graded homomorphism: r(-2) + r + r(4)^2 <- r(-2) + r + r(4)^2, given by a\
diagonal matrix, with degrees:
⇒ ..1 ..2 ..3 ..4 ....
⇒ --- --- --- --- +...
⇒ 2 : 0 - - - |..1
⇒ 0 : - 0 - - |..2
⇒ -4 : - - 0 - |..3
⇒ -4 : - - - 0 |..4
⇒      === === === ===
⇒      2 0 -4 -4
module K = grsyz( L ); grview(K);
⇒ Graded homomorphism: r(-2) + r + r(4)^2 <- 0, given by zero (4 x 0) matrix.
x.
// Corner cases: 0 <- 0!
module Z = grzero(); grview(Z);
⇒ Graded homomorphism: 0 <- 0, given by zero (0^2) matrix.
grview( grtranspose( Z ) );
⇒ Graded homomorphism: 0 <- 0, given by zero (0^2) matrix.
// Corner cases: * <- 0

```

```

matrix M1[3][0];
module Z1 = grobj( M1, intvec(-1, 0, 1) ); grview(Z1);
⇒ Graded homomorphism:  $r(1) + r + r(-1) \leftarrow 0$ , given by zero (3 x 0) matrix.
grview( grtranspose( Z1 ) );
⇒ Graded homomorphism:  $0 \leftarrow r(-1) + r + r(1)$ , given by zero (0 x 3) matrix.
// Corner cases: 0 ← *
matrix M2[0][3];
module Z2 = grobj( M2, 0:0, intvec(-1, 0, 1) ); grview(Z2);
⇒ Graded homomorphism:  $0 \leftarrow r(1) + r + r(-1)$ , given by zero (0 x 3) matrix.
grview( grtranspose( Z2 ) );
⇒ Graded homomorphism:  $r(-1) + r + r(1) \leftarrow 0$ , given by zero (3 x 0) matrix.

```

D.15.7.12 grgens

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grgens(M)`, graded object `M` (map)

Return: graded object

Purpose: try compute graded generators of `coker(M)` and return them as columns of a graded map.

Note: presentation of resulting generated submodule may be different to `M`!

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
module M = grtwists( intvec(-2, 0, 4, 4) ); grview(M);
⇒ Graded homomorphism:  $r(-2) + r + r(4)^2 \leftarrow 0$ , given by zero (4 x 0) matrix.
x.
module N = grgens(M);
grview( N ); print(N); // fine == M
⇒ Graded homomorphism:  $r(-2) + r + r(4)^2 \leftarrow r(-2) + r + r(4)^2$ , given by a\
diagonal matrix, with degrees:
⇒      ..1 ..2 ..3 ..4 ....
⇒      --- --- --- --- +...
⇒      2 :  0  -  -  - |..1
⇒      0 :  -  0  -  - |..2
⇒     -4 :  -  -  0  - |..3
⇒     -4 :  -  -  -  0 |..4
⇒      === === === ===
⇒      2   0  -4  -4
⇒ 1,0,0,0,
⇒ 0,1,0,0,
⇒ 0,0,1,0,
⇒ 0,0,0,1
module A = grobj( module([x+y, x, 0, 3], [0, x+y, y, 2], [y, y, z, 1]), intvec(0,0,0,0) );
A = grgroebner(A); grview(A);
⇒ Graded homomorphism:  $r^3 + r(-1) \leftarrow r(-1)^3 + r(-2) + r(-3)$ , given by a m\
atrix, with degrees:
⇒      ..1 ..2 ..3 ..4 ..5 ....
⇒      --- --- --- --- --- +...
⇒      0 :  1   1   1   2   - |..1
⇒      0 :  1   -   1   -   - |..2

```

```

⇒ 0 : 1 1 1 2 3 |..3
⇒ 1 : 0 0 0 1 2 |..4
⇒      === === === === ===
⇒      1 1 1 2 3
module B = grgens(A);
grview( B ); print(B); // Ups :( != A
⇒ Graded homomorphism: r(2) <- r^3 + r(-1), given by a matrix, with degrees\
:
⇒      ..1 ..2 ..3 ..4 ....
⇒      --- --- --- --- +...
⇒ -2 : 2 2 2 3 |..1
⇒      === === === ===
⇒      0 0 0 1
⇒ xy-3y^2+xz+3yz,-xy+2y^2+2xz+2yz,x^2-xy-4y^2,y^3-x^2z-2xyz-y^2z
grview( grgens( grzero() ) );
⇒ Graded homomorphism: 0 <- 0, given by zero (0^2) matrix.

```

D.15.7.13 grpres

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grpres(M)`, graded object `M` (submodule gens)

Return: graded module (via coker)

Purpose: compute graded presentation matrix of submodule generated by columns of `M`

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
def A = grgroebner( grobj( module([x+y, x, 0, 3], [0, x+y, y, 2], [y, y, z, 1]), int
grview(A);
⇒ Graded homomorphism: r^3 + r(-1) <- r(-1)^3 + r(-2) + r(-3), given by a m\
atrix, with degrees:
⇒      ..1 ..2 ..3 ..4 ..5 ....
⇒      --- --- --- --- --- +...
⇒ 0 : 1 1 1 2 - |..1
⇒ 0 : 1 - 1 - - |..2
⇒ 0 : 1 1 1 2 3 |..3
⇒ 1 : 0 0 0 1 2 |..4
⇒      === === === === ===

```

D.15.7.14 grorder

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grorder(M)`, graded object or list M

Return: same as input

Purpose: reorder/transform graded object or chain complex M into block form

Assume: M must be a graded object or a list of graded objects

Example:

```

LIB "gradedModules.lib";
"Surface Name: 'rat.d10.g9.quart2' in P^4";
⇒ Surface Name: 'rat.d10.g9.quart2' in P^4
int @p=31991; ring R = (@p),(x,y,z,u,v), dp;

```

D.15.7.15 grtranspose1

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grtranspose1(M)`, graded object or list M

Return: same as input

Purpose: graded transpose of graded object or chain complex M

Assume: M must be a graded object or a list of graded objects

Example:

```

LIB "gradedModules.lib";
"Surface Name: 'k3.d10.g9.quart2' in P^4";
⇒ Surface Name: 'k3.d10.g9.quart2' in P^4

D.15.7.16 TestGRRes

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: TestGRRes(name, I), string name, ideal I

Return: nothing

Purpose: compute/test/output/order/transpose a graded resolution of I

Example:

```

LIB "gradedModules.lib";
// if( defined(assumeLevel) ){ int assumeLevel0 = assumeLevel; } else { int assumeLevel0 = 0; }
// note: data from random generation 2
string Name = "castelnuovo"; int @p=31991; ring R = (@p),(x,y,z,u,v), dp;ideal I = 5
↳ =====

D.15.7.17 KeneshlouMatrixPresentation

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `KeneshlouMatrixPresentation(intvec a), intvec a.`

Return: graded object

Purpose: matrix presentation for direct sum of ω^ai in form of a graded object

Example:

```

LIB "gradedModules.lib";
ring r = 32003,(x(0..4)),dp;
def N1 = KeneshlouMatrixPresentation(intvec(2,0,0,0,0));
grview(N1);

D.15.7.18 grsyz

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grsyz(M)`, graded object `M`

Return: graded object

Purpose: compute graded syzygy of `M`

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
module A = grgroebner( grobj( module([x+y, x, 0, 3], [0, x+y, y, 2], [y, y, z, 1]), :
grview(A);
↳ Graded homomorphism:  $r^3 + r(-1) \leftarrow r(-1)^3 + r(-2) + r(-3)$ , given by a m\
atrix, with degrees:

```

```

⇒      ..1 ..2 ..3 ..4 ..5 ....
⇒      --- --- --- --- --- +...
⇒      0 :  1   1   1   2   - |..1
⇒      0 :  1   -   1   -   - |..2
⇒      0 :  1   1   1   2   3 |..3
⇒      1 :  0   0   0   1   2 |..4
⇒      === === === === ===
⇒      1   1   1   2   3
grview(grsyz(A));
⇒ Graded homomorphism: r(-1)^3 + r(-2) + r(-3) <- r(-2) + r(-3), given by a\
  matrix, with degrees:
⇒      ..1 ..2 ....
⇒      --- --- +...
⇒      1 :  1   - |..1
⇒      1 :  1   2 |..2
⇒      1 :  1   - |..3
⇒      2 :  0   1 |..4
⇒      3 :  -   0 |..5
⇒      === ===
⇒      2   3
module X = grgroebner( grobj( module([x]), intvec(2) ) );
grview(X);
⇒ Graded homomorphism: r(-2) <- r(-3), given by a diagonal matrix, with deg\
  rees:
⇒      .1 ...
⇒      -- +..
⇒      2 : 1 |.1
⇒      ==
⇒      3
// syzygy module should be zero!
grview(grsyz(X));
⇒ Graded homomorphism: r(-3) <- 0, given by zero (1 x 0) matrix.

```

D.15.7.19 grres

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grres(M, l[, b])`, graded object M, int l, int b

Return: graded resolution = list of graded objects

Purpose: compute graded resolution of M (of length l) and minimise it if b was given

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
module A = grobj( module([x+y, x, 0, 3], [0, x+y, y, 2], [y, y, z, 1]), intvec(0,0,0) );
grview(A);
⇒ Graded homomorphism: r^3 + r(-1) <- r(-1)^3, given by a matrix, with degr\
  ees:
⇒      ..1 ..2 ..3 ....
⇒      --- --- --- +...
⇒      0 :  1   -   1 |..1
⇒      0 :  1   1   1 |..2
⇒      0 :  -   1   1 |..3

```

```

⇒ 1 : 0 0 0 |..4

⇒ Graded homomorphism: r(-1) + r(-2) + r(-1)^2 + r(-3) <- 0, given by zero \
(5 x 0) matrix.

```

D.15.7.20 grlift

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\], page 2388](#)).

Usage: `grlift(M, N)`, graded objects M and N

Return: transformation matrix (graded object???)

Purpose: compute graded matrix which the generators of submodule $\text{Im}(N)$ in terms of $\text{Im}(M)$.

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
module P=grobj(module([xy,0,xz]),intvec(0,1,0));
grview(P);
⇒ Graded homomorphism: r + r(-1) + r <- r(-2), given by a matrix, with degr\
ees:
⇒      ..1 ....
⇒      --- +...
⇒      0 :  2 |..1
⇒      1 :  - |..2
⇒      0 :  2 |..3
⇒      ===
⇒      2
module D=grobj(module([y,0,z],[x2+y2,z,0]),intvec(0,1,0));
grview(D);
⇒ Graded homomorphism: r + r(-1) + r <- r(-1) + r(-2), given by a matrix, w\
ith degrees:
⇒      ..1 ..2 ....
⇒      --- --- +...
⇒      0 :  1  2 |..1
⇒      1 :  -  1 |..2
⇒      0 :  1  - |..3
⇒      === ===
⇒      1  2
def G=grlift(D,P);
grview(G);
⇒ Graded homomorphism: r(-1) + r(-2) <- r(-2), given by a matrix, with degr\
ees:
⇒      ..1 ....
⇒      --- +...
⇒      1 :  1 |..1
⇒      2 :  - |..2
⇒      ===
⇒      2
ASSUME(0, grisegal( grprod(D, G), P ));

```

D.15.7.21 grprod

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\], page 2388](#)).

Usage: `grprod(M, N)`, graded objects M and N

Return: graded object

Purpose: compute graded product $M * N$ (as composition of maps)

Example:

```
LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
module A = grobj( module([x+y, x, 0, 3], [0, x+y, y, 2], [y, y, z, 1]), intvec(0,0,0
grview(A);

↳      === ===
↳      2   3
print(B);
↳ x, 0,
↳ -y,y2,
↳ -y,0,
↳ 1, -x-2y,
↳ 0, 1
module D = grprod( A, B );
grview(D);
↳ Graded homomorphism:  $r^3 + r(-1) \leftarrow r(-2) + r(-3)$ , given by zero (4 x 2) \
matrix.
```

```

print(D); // must be all zeroes due to syzygy property!
⇒ 0,0,
⇒ 0,0,
⇒ 0,0,
⇒ 0,0
ASSUME(0, size(D) == 0);

```

D.15.7.22 grgroebner

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\], page 2388](#)).

Usage: `grgroebner(M)`, graded object `M`

Return: graded object

Purpose: compute graded groebner basis of `M`

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
module A = grobj( module([x+y, x, 0, 0], [0, x+y, y, 0]), intvec(0,0,0,1) );
grview(A);
⇒ Graded homomorphism: r^3 + r(-1) <- r(-1)^2, given by a matrix, with degr\
  ees:
⇒      ..1 ..2 ....
⇒      --- --- +...
⇒  0 :  1   - |..1
⇒  0 :  1   1 |..2
⇒  0 :  -   1 |..3
⇒  1 :  -   - |..4
⇒      === ===
⇒      1   1
module B = grgroebner(A);
grview(B);
⇒ Graded homomorphism: r^3 + r(-1) <- r(-1)^2, given by a matrix, with degr\
  ees:
⇒      ..1 ..2 ....
⇒      --- --- +...
⇒  0 :  1   - |..1
⇒  0 :  1   1 |..2
⇒  0 :  1   1 |..3
⇒  1 :  -   - |..4
⇒      === ===
⇒      1   1

```

D.15.7.23 grconcat

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\], page 2388](#)).

Usage: `grconcat(A, B)`, graded objects `A` and `B`, `dst(A) == dst(B) ==: dst`

Return: graded object

Purpose: construct `src(A) + src(B) → dst` given by `(A|B)`

Example:

```

LIB "gradedModules.lib";
ring r;
module R=grobj(module([x,y,z]),intvec(0:3));
grview(R);
⇒ Graded homomorphism:  $r^3 \leftarrow r(-1)$ , given by a matrix, with degrees:
⇒      .1 ...
⇒      -- +..
⇒      0 : 1 |.1
⇒      0 : 1 |.2
⇒      0 : 1 |.3
⇒      ==
⇒      1
module S=grobj(module([x,0,y],[xy,zy+x2,0]),intvec(0:3));
grview(S);
⇒ Graded homomorphism:  $r^3 \leftarrow r(-1) + r(-2)$ , given by a matrix, with degree\
  s:
⇒      ..1 ..2 ....
⇒      --- --- +...
⇒      0 : 1 2 |..1
⇒      0 : - 2 |..2
⇒      0 : 1 - |..3
⇒      === ===
⇒      1 2
def Q=grconcat(R,S);
grview(Q);
⇒ Graded homomorphism:  $r^3 \leftarrow r(-1)^2 + r(-2)$ , given by a square matrix, wi\
  th degrees:
⇒      ..1 ..2 ..3 ....
⇒      --- --- --- +...
⇒      0 : 1 1 2 |..1
⇒      0 : 1 - 2 |..2
⇒      0 : 1 1 - |..3
⇒      === === ===
⇒      1 1 2

```

D.15.7.24 grndmat

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grndmat(src,dst[,p,b]), intvec src, dst[, int p, b]`

Return: matrix of polynomials

Purpose: generate random matrix compatible with src and dst gradings

Note: optional arguments p, b are for 'sparsepoly' (by default: 75%, 30000).

Todo: this is experimental at the moment!

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
print( grndmat( intvec(0, 1), intvec(1, 2, 3) ) );
⇒ 6204y, -7833,
⇒ -12498xz+12773z2, 5664z,
⇒ -10041x3-11973x2y-5644xy2,-7740xy-5361z2

```

D.15.7.25 grndmap

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\], page 2388](#)).

Usage: `grndmap(S,D)`, graded objects S and D

Return: graded object

Purpose: construct a random 0-deg graded homomorphism $\text{src}(S) \rightarrow \text{src}(D)$

Example:

```
LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
module D=grobbj(module([y,0,z],[x2+y2,z,0]),intvec(0,1,0));
grview(D);
↳ Graded homomorphism: r + r(-1) + r <- r(-1) + r(-2), given by a matrix, w\
ith degrees:
↳      ..1 ..2 ....
↳      --- --- +...
↳      0 :  1   2 |..1
↳      1 :  -   1 |..2
↳      0 :  1   - |..3
↳      === ===
↳      1   2
module S=grobbj(module([x,0,y],[xy,zy+x2,0]),intvec(0,0,0));
grview(S);
↳ Graded homomorphism: r^3 <- r(-1) + r(-2), given by a matrix, with degree\
s:
↳      ..1 ..2 ....
↳      --- --- +...
↳      0 :  1   2 |..1
↳      0 :  -   2 |..2
↳      0 :  1   - |..3
↳      === ===
↳      1   2
def H=grndmap(D,S);
grview(H);
↳ Graded homomorphism: r(-1) + r(-2) <- r(-1) + r(-2), given by a square ma\
trix, with degrees:
↳      ..1 ..2 ....
↳      --- --- +...
↳      1 :  0   1 |..1
↳      2 :  -   0 |..2
↳      === ===
↳      1   2
```

D.15.7.26 grndmap2

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\], page 2388](#)).

Usage: `grndmap2(D,S)`, graded objects S and D

Return: graded object

Purpose: construct a random 0-deg graded homomorphism between target of D and S .

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
module D=grobj(module([y,0,z],[x2+y2,z,0]),intvec(0,1,0));
grview(D);
⇒ Graded homomorphism:  $r + r(-1) + r \leftarrow r(-1) + r(-2)$ , given by a matrix, with
degrees:
⇒      ..1 ..2 ....
⇒      --- --- +...
⇒  0 :  1   2 |..1
⇒  1 :  -   1 |..2
⇒  0 :  1   - |..3
⇒      === ===
⇒      1   2
module S=grobj(module([x,0,y],[xy,zy+x2,0]),intvec(0,0,0));
grview(S);
⇒ Graded homomorphism:  $r^3 \leftarrow r(-1) + r(-2)$ , given by a matrix, with degree\
s:
⇒      ..1 ..2 ....
⇒      --- --- +...
⇒  0 :  1   2 |..1
⇒  0 :  -   2 |..2
⇒  0 :  1   - |..3
⇒      === ===
⇒      1   2
def G=grrndmap2(D,S);
grview(G);
⇒ Graded homomorphism:  $r^3 \leftarrow r + r(-1) + r$ , given by a square matrix, with\
degrees:
⇒      .1 .2 .3 ...
⇒      -- -- -- +..
⇒  0 :  0  1  0 |.1
⇒  0 :  0  1  0 |.2
⇒  0 :  0  1  0 |.3
⇒      == == ==
⇒      0  1  0

```

D.15.7.27 grlifting

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grlifting(M,N)`, graded objects M and N

Return: map of chain complexes (as a list)

Purpose: construct a map of chain complexes between free resolutions of $\text{Img}(M)$ and $\text{Img}(N)$.

Example:

```

LIB "gradedModules.lib";
/*
ring r=32003,(x,y,z),dp;
module P=grobj(module([xy,0,xz]),intvec(0,1,0));
grview(P);
module D=grobj(module([y,0,z],[x2+y2,z,0]),intvec(0,1,0));
grview(D);
def G=grlifting(D,P);

```

```

grview(G);
kill r;
ring r=32003,(x,y,z),dp;
module D=grojb(module([y,0,z],[x2+y2,z,0],[z3,xy,xy2]),intvec(0,1,0));
D = grgroebner(D);
grview( grres(D, 0));
def G=grlifting(D, D);
grview(G);
*/

D.15.7.28 grlifting2

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\], page 2388](#)).

Usage: `grlifting2(A,B)`, graded objects A and B (matrices defining maps)

Return: map of chain complexes (as a list)

Purpose: construct a map of chain complexes between free resolution of $M=\text{coker}(A)$ and $N=\text{coker}(B)$.

Example:

```

LIB "gradedModules.lib";
ring r;
module P=grobj(module([xy,0,xz]),intvec(0,1,0));
grview(P);
⇒ Graded homomorphism: r + r(-1) + r <- r(-2), given by a matrix, with degr\
ees:
⇒      ..1 ....
⇒      --- +...
⇒      0 : 2 |..1
⇒      1 : - |..2
⇒      0 : 2 |..3
⇒      ===
⇒      2
module D=grobj(module([y,0,z],[x2+y2,z,0]),intvec(0,1,0));
grview(D);
⇒ Graded homomorphism: r + r(-1) + r <- r(-1) + r(-2), given by a matrix, w\
ith degrees:
⇒      ..1 ..2 ....
⇒      --- --- +...
⇒      0 : 1 2 |..1
⇒      1 : - 1 |..2
⇒      0 : 1 - |..3
⇒      === ===
⇒      1 2
module PP = grpres(P);
grview(PP);

```

```

↳ Graded homomorphism:  $r(-2) \leftarrow 0$ , given by zero (1 x 0) matrix.
module DD = grpres(D);
grview(DD);
↳ Graded homomorphism:  $r(-1) + r(-2) \leftarrow 0$ , given by zero (2 x 0) matrix.
def T=grlifting2(DD,PP); T;
↳ T[1]=0
↳ T[2]=-5361*gen(1)
// def Z=grlifting2(P,D); Z; // WRONG!!!

```

D.15.7.29 mappingcone

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `mappingcone(M,N)`, M,N graded objects

Return: chain complex (as a list)

Purpose: construct a free resolution of the cokernel of a random map between $\text{Img}(M)$, and $\text{Img}(N)$.

Example:

```

LIB "gradedModules.lib";
ring r=32003, (x(0..4)),dp;
def A=KeneshlouMatrixPresentation(intvec(0,0,0,0,3));
def M=grgens(A);
grview(M);
↳ Graded homomorphism:  $r(-1)^3 \leftarrow r(-1)^3$ , given by a diagonal matrix, with\
degrees:
↳
  ..1 ..2 ..3 ....
↳   --- --- --- +...
↳  1 :  0  -  - |..1

D.15.7.31 mappingcone3

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: mappingcone3(A,B), graded objects A and B (matrices defining maps)

Return: chain complex (as a list)

Purpose: construct a free resolution of the cokernel of a random map between $M=\text{coker}(A)$, and $N=\text{coker}(B)$

Example:

```
LIB "gradedModules.lib";
```

```

ring r=32003,x(0..4),dp;
def A=KeneshlouMatrixPresentation(intvec(0,0,0,0,3));
grview(A);
↳ Graded homomorphism:  $r(-1)^3 \leftarrow 0$ , given by zero (3 x 0) matrix.
def T= KeneshlouMatrixPresentation(intvec(0,1,0,0,0));
grview(T);
↳ Graded homomorphism:  $r(-1)^{10} \leftarrow r(-2)^{10}$ , given by a square matrix, with\
degrees:
↳      ..1 ..2 ..3 ..4 ..5 ..6 ..7 ..8 ..9 .10 ....

D.15.7.32 grrange

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grrange(M)`, graded object `M`

Return: `intvec`

Purpose: get weights of module units, thus describing the target of `M`

Example:

```

LIB "gradedModules.lib";
ring r=32003,(x,y,z),dp;
module Z = grobj(freemodule(0),intvec(0:0),intvec(0:0));
grrange(Z);
↳
grdeg(Z);

```

```

⇒
grview(Z);
⇒ Graded homomorphism: 0 <- 0, given by zero (0^2) matrix.
module P=grobj(module([xy,0,xz]),intvec(0,1,0));
grrange(P);
⇒ 0,1,0
grdeg(P);
⇒ 2
grview(P);
⇒ Graded homomorphism: r + r(-1) + r <- r(-2), given by a matrix, with degr\
ees:
⇒      ..1 ....
⇒      --- +...
⇒ 0 : 2 |..1
⇒ 1 : - |..2
⇒ 0 : 2 |..3
⇒      ===
⇒      2

```

D.15.7.33 grneg

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `grneg(A)`, graded object A

Return: graded object

Purpose: graded map defined by -A

Example:

```

LIB "gradedModules.lib";
ring r=0,(x,y,z),dp;
def A=grobj([x2,yz,xyz],intvec(1,1,0));
grview(A);
⇒ Graded homomorphism: r(-1)^2 + r <- r(-3), given by a matrix, with degree\
s:
⇒      .1 ...
⇒      -- +..
⇒ 1 : 2 |.1
⇒ 1 : 2 |.2
⇒ 0 : 3 |.3
⇒      ==
⇒      3
def F=grneg(A);
grview(F);
⇒ Graded homomorphism: r(-1)^2 + r <- r(-3), given by a matrix, with degree\
s:
⇒      .1 ...
⇒      -- +..
⇒ 1 : 2 |.1
⇒ 1 : 2 |.2
⇒ 0 : 3 |.3
⇒      ==
⇒      3

```

D.15.7.34 matrixpres

Procedure from library `gradedModules.lib` (see [Section D.15.7 \[gradedModules.lib\]](#), page 2388).

Usage: `matrixpres(a), intvec a`

Return: graded object

Purpose: matrix presentation for direct sum of ω^ai in form of a graded object

Example:

```
LIB "gradedModules.lib";
ring r = 32003,(x(0..4)),dp;
def R=matrixpres(intvec(1,4,0,0,0));
⇒ // ** redefining j (      int j=size(a)-i;) gradedModules.lib:matrixpres\
:2480
grview(R);
⇒ Graded homomorphism: r(-1)^21 <- r(-2)^4, given by a matrix, with degrees\

D.15.8 hodge.lib

Library: hodge.lib

Purpose: Algorithms for Hodge ideals

Authors: Guillem Blanco, email: guillem.blanco@kuleuven.be

Overview: A library for computing the Hodge ideals [MP19] of \mathbb{Q} -divisors associated to any reduced hypersurface $\text{fin}R$.

The implemented algorithm [Bla21] is based on the characterization of the Hodge ideals in terms of the V -filtration of Malgrange and Kashiwara on $R_f f^s$, see [MP20].

As a consequence, this library provides also an algorithm to compute the multiplier ideals and the jumping numbers of any hypersurface, see [BS05].

References:

[Bla21] G. Blanco, An algorithm for Hodge ideals, to appear.

[MP20] M. Mustata, M. Popa: Hodge ideals for \mathbb{Q} -divisors, V -filtration, and minimal exponent, Forum Math. Sigma 8 (2020), no. e19, 41 pp.

Procedures: See also: [Section 7.5.5 \[dmodapp.lib\]](#), [page 421](#).

D.15.8.1 Vfiltration

Procedure from library `hodge.lib` (see [Section D.15.8 \[hodge.lib\]](#), [page 2464](#)).

Usage: `Vfiltration(f, p [, eng]);` f a poly, p a non-negative integer, eng an optional integer.

Return: ring

Purpose: compute R -generators for the V -filtration on $R_f f^s$ truncated up to degree p in ∂_t .

Note: activate the output ring with the `setring` command.

In the output ring, the list `Vfilt` contains the V -filtration.

The value of `eng` controls the algorithm used for Groebner basis computations.

See the `engine` procedure from [Section 7.5.5 \[dmodapp_lib\]](#), page 421 for the available algorithms.

Display: If `printlevel=1`, progress debug messages will be printed.

Example:

```
LIB "hodge.lib";
ring R = 0,(x,y),dp;
poly f = y^2-x^3;
def D = Vfiltration(f, 1);
setring D; Vfilt;

D.15.8.2 hodgeIdeals

Procedure from library `hodge.lib` (see [Section D.15.8 \[hodge.lib\]](#), [page 2464](#)).

Usage: `hodgeIdeals(f, p [, eng]);` f a reduced poly, p a non-negative integer, eng an optional integer.

Return: ring

Purpose: compute the Hodge ideals of f^α up to level p , for a reduced hypersurface f .

Note: activate the output ring with the `setring` command.
 In the output ring, the list of ideals `hodge` contains the Hodge ideals of f .
 The value of `eng` controls the algorithm used for Groebner basis computations.
 See the `engine` procedure from [Section 7.5.5 \[dmodapp.lib\]](#), [page 421](#) for the available algorithms.

Display: If `printlevel=1`, progress debug messages will be printed.

Example:

```

LIB "hodge.lib";
ring R = 0,(x,y),dp;
poly f = y^2-x^3;
def Ra = hodgeIdeals(f, 2);
setring Ra; hodge;

D.15.8.3 multIdeals

Procedure from library `hodge.lib` (see [Section D.15.8 \[hodge.lib\]](#), page 2464).

Usage: `multIdeals(f, [, eng]);` f a reduced poly, `eng` an optional integer.

Return: list

Purpose: compute the multiplier ideals of a hypersurface $f \in R$.

Note: The value of `eng` controls the algorithm used for Groebner basis computations. See the `engine` procedure from [Section 7.5.5 \[dmodapp.lib\]](#), page 421 for the available algorithms.

Display: If `printlevel=1`, progress debug messages will be printed.

Example:

```

LIB "hodge.lib";
ring R = 0,(x,y),dp;
poly f = y^2-x^3;
multIdeals(f);
↳ [1]:
↳ [1]:

↳ 5/6
↳ [3]:
↳ 1
↳ [2]:
↳ [1]:
↳ _[1]=y
↳ _[2]=x
↳ [2]:
↳ 1

```

```

    ↦      [3]:
    ↦      1

```

D.15.8.4 nextHodgeIdeal

Procedure from library `hodge.lib` (see [Section D.15.8 \[hodge.lib\]](#), page 2464).

Usage: `nextHodgeIdeal(f, I, p);` f a poly, I an ideal, p a non-negative integer

Return: ideal

Purpose: given the p -th Hodge ideal I of f^α compute the $p+1$ -th Hodge ideal assuming that the Hodge filtration of the underlying mixed Hodge module is generated at level less than or equal to p .

Example:

```

LIB "hodge.lib";
ring R = 0,(x,y),dp;
poly f = y^2-x^3;
def Ra = hodgeIdeals(f, 2);
setring(Ra);
int p = 1;
nextHodgeIdeal(y^2-x^3, hodge[3][1][p+1], p);
↦ _[1]=x^2*y^2
↦ _[2]=y^3
↦ _[3]=x^3*y
↦ _[4]=x^4+(2*a+1)*x*y^2

```

D.15.9 lrcalc_lib

Library: `lrcalc.lib`

Purpose: An interface to the Littlewood-Richardson Calculator by Anders Buch

Author: Oleksandr Iena, o.g.yena@gmail.com

Overview: An interface to the documented functions of the Littlewood-Richardson Calculator by Anders Buch is implemented.

The library requires the Littlewood-Richardson Calculator by Anders Buch, which is available at <http://math.rutgers.edu/~asbuch/lrcalc/>

References:

[1] <http://math.rutgers.edu/~asbuch/lrcalc/>
<http://math.rutgers.edu/~asbuch/lrcalc/lrcalc-1.2/README>

Procedures:

D.15.9.1 LRinstall

Procedure from library `lrcalc.lib` (see [Section D.15.9 \[lrcalc.lib\]](#), page 2468).

Usage: `LRinstall();`

Return: int (exit status of the shell)

Purpose: installs the Littlewood-Richardson Calculator

Note:

Example:

```
LIB "lrcalc.lib";
// In order to install the Littlewood-Richardson Calculator
// type "LRinstall();"
// This will execute the following commands:
// wget math.rutgers.edu/~asbuch/lrcalc/lrcalc-1.2.tar.gz
// tar zxvf lrcalc-1.2.tar.gz
// cd lrcalc-1.2
// ./configure
// make
// sudo make install
```

D.15.9.2 LRcoef

Procedure from library `lrcalc.lib` (see [Section D.15.9 \[lrcalc.lib\]](#), page 2468).

Usage: `LRcoef(z, x, y)`; `z, x, y` lists of integers (partitions)

Return: bigint

Purpose: computes the Littlewood-Richardson coefficient $c^z_{x,y}$

Note:

Example:

```
LIB "lrcalc.lib";
// Compute the Littlewood-Richardson coefficient  $c^z_{x,y}$ 
// for  $z = (3, 2, 1)$ ,  $x = (2, 1)$ ,  $y = (2, 1)$ 
list z = 3, 2, 1;
list x = 2, 1;
list y = 2, 1;
LRcoef(z, x, y);
↦ 2
```

D.15.9.3 LRskew

Procedure from library `lrcalc.lib` (see [Section D.15.9 \[lrcalc.lib\]](#), page 2468).

Usage: `LRskew(z, x [,s, r])`; `z, x` lists of integers (partitions) `s` string equal to 'r', `r` non-negative integer

Return: list of lists

Purpose: computes the partitions `y` for which the Littlewood-Richardson coefficient $c^z_{x,y}$ is non-zero together with that coefficient; only partitions up to length `r` are computed if the optional parameters `age` given

Note:

Example:

```
LIB "lrcalc.lib";
// Compute the partitions y for which the Littlewood-Richardson coefficient
//  $c^z_{x,y}$  is non-zero together with that coefficient
// for  $z = (3, 2, 1)$ ,  $x = (2, 1)$ 
list z = 3, 2, 1;
list x = 2, 1;
LRskew(z, x);
```

```

D.15.9.4 LRmult

Procedure from library `lrcalc.lib` (see [Section D.15.9 \[lrcalc.lib\]](#), page 2468).

Usage: LRmult(x, y); x, y lists of integers (partitions)
 LRmult(x, y [, s, r]); x, y lists of integers (partitions), s string equal to 'r', r integer
 LRmult(x, y [, s, m, k]); x, y lists of integers (partitions), s string equal to 'q' or 'f',
 m, k integers

Return: list of lists

Purpose: computes the partitions z for which the Littlewood-Richardson coefficient $c^z_{x,y}$ is non-zero together with that coefficient; partitions up to length r

Note:**Example:**

```

LIB "lrcalc.lib";
// Compute the partitions z for which the Littlewood-Richardson coefficient
// c^z_{x,y} is non-zero together with that coefficient
// for x= (2, 1), y=(2, 1)
list x = 2, 1;
list y = 2, 1;
LRmult(x, y);

D.15.9.5 LRcoprod

Procedure from library `lrcalc.lib` (see [Section D.15.9 \[lrcalc.lib\]](#), page 2468).

Usage: LRcoprod(z); z list of integers (partition)

Return: list of lists

Purpose: computes the pairs of partitions x and y for which the Littlewood-Richardson coefficient $c^z_{x,y}$ is non-zero together with that coefficient

Note:

Example:

```

LIB "lrcalc.lib";
// Compute the pairs of partitions x and y for which the Littlewood-Richardson
// coefficient  $c^z_{x,y}$  is non-zero together with that coefficient
// for z= (3, 2, 1)
list z = 3, 2, 1;
LRcoprod(z);

D.15.9.6 LRschubmult

Procedure from library `lrcalc.lib` (see [Section D.15.9 \[lrcalc.lib\]](#), page 2468).

Usage: LRschubmult(x, y); x, y lists of integers

Return: list of lists

Purpose: computes the expansion of a product
of two Schubert polynomials in the basis of Schubert polynomials

Note:

Example:

```

LIB "lrcalc.lib";
// Compute the expansion of a square of the Schubert polynomial
// corresponding to (1 3 2) in the basis of Schubert polynomials
list x = 1, 3, 2;

D.15.10 maxlike.lib

Library: maxlike.lib

Purpose: Procedures to compute maximum likelihood estimates

Author: Adrian Koch (kocha at rhrk.uni-kl.de)

References:

Lior Pachter, Bernd Sturmfels; Algebraic Statistics for Computational Biology; published by Cambridge University Press

Procedures:**D.15.10.1 likeIdeal**

Procedure from library `maxlike.lib` (see [Section D.15.10 \[maxlike.lib\]](#), page 2477).

Usage: `likeIdeal(I,u)`; ideal I , intvec u
 I represents the algebraic statistical model and u is the data vector under consideration.

Return: ideal: the likelihood ideal with respect to I and u

Example:

```
LIB "maxlike.lib";
ring r = 0,(x,y),dp;
poly pA = -10x+2y+25;
poly pC = 8x-y+25;
poly pG = 11x-2y+25;
poly pT = -9x+y+25;
intvec u = 10,14,15,10;
ideal I = pA,pC,pG,pT;
ideal L = likeIdeal(I,u); L;
⇒ L[1]=2744y2+13003050x-2116125y-6290625
⇒ L[2]=9114xy-98y2+5828550x-891375y-2833125
⇒ L[3]=847602x2-98y2+89716875x-12967425y-43985625
```

D.15.10.2 logHessian

Procedure from library `maxlike.lib` (see [Section D.15.10 \[maxlike.lib\]](#), page 2477).

Usage: `logHessian(I,u)`; ideal I , intvec u
 I represents the algebraic statistical model and u is the data vector under consideration.

Return: matrix: a modified version of the Hessian matrix of the loglikelihood function defined by u and (the given generators of) I .

Note: This matrix has the following property: if it is negative definite at a point, then the actual Hessian is also negative definite at that point. The same holds for positive definiteness.

Example:

```
LIB "maxlike.lib";
ring r = 0,(x,y),dp;
poly pA = -10x+2y+25;
poly pC = 8x-y+25;
poly pG = 11x-2y+25;
poly pT = -9x+y+25;
intvec u = 10,14,15,10;
ideal I = pA,pC,pG,pT;
matrix H = logHessian(I,u); H;
⇒ H[1,1]=-689040x3+314898x2y-44808xy2+1974y3+9619350x2-2949075xy+240975y2+6\
151875x-1072500y-70640625
⇒ H[1,2]=110880x3-51936x2y+7596xy2-348y3-1489200x2+431400xy-33450y2-1072500\
```

```

x+176250y+11437500
⇒ H[2,1]=110880x3-51936x2y+7596xy2-348y3-1489200x2+431400xy-33450y2-1072500\
x+176250y+11437500
⇒ H[2,2]=-16580x3+7972x2y-1192xy2+56y3+243150x2-66800xy+4900y2+176250x-2750\
0y-1937500

```

D.15.10.3 getMaxPoints

Procedure from library `maxlike.lib` (see [Section D.15.10 \[maxlike.lib\]](#), page 2477).

Usage: `getMaxPoints(Iu, H, prec [, "nodisplay"])`; ideal `Iu`, matrix `H`, int `prec`, int `k` `Iu` the likelihood ideal, `H` the (modified) Hessian of the considered algebraic statistical model, `prec` the precision with which to compute the maximum likelihood estimates

Return: ring: a complex ring `R` in which you can find the following two lists: - `MPOINTS`, points in which the loglikelihood function has a local maximum, and - `LHESSIANS`, the (modified) Hessians at those points
also prints out the points in `MPOINTS`, unless a fourth argument is given

Note: it is assumed that the likelihood ideal is 0-dimensional

Example:

```

LIB "maxlike.lib";
ring r = 0,(x,y),dp;
poly pA = -10x+2y+25;
poly pC = 8x-y+25;
poly pG = 11x-2y+25;
poly pT = -9x+y+25;
intvec u = 10,14,15,10;
ideal I = pA,pC,pG,pT;
ideal L = likeIdeal(I,u);
matrix H = logHessian(I,u);
def R = getMaxPoints(L, H, 50);

D.15.10.4 maxPoints

Procedure from library `maxlike.lib` (see [Section D.15.10 \[maxlike.lib\]](#), page 2477).

Usage: `maxPoints(I,u,prec [, "nodisplay"])`; ideal `I`, intvec `u`, int `prec` `I` represents the algebraic statistical model, `u` is the data vector under consideration, and `prec` is the precision to be used in the computations

Return: ring: a complex ring `R` in which you can find the following two lists: - `MPOINTS`, points in which the loglikelihood function has a local maximum, and - `LHESSIANS`, the (modified) Hessians at those points
also prints out the points in `MPOINTS`, unless a fourth argument is given

Note: Just uses `likeideal`, `loghessian` and `getmaxpoints`.

Example:

```

LIB "maxlike.lib";
ring r = 0,(x,y),dp;
poly pA = -10x+2y+25;
poly pC = 8x-y+25;
poly pG = 11x-2y+25;
poly pT = -9x+y+25;
intvec u = 10,14,15,10;
ideal I = pA,pC,pG,pT;
def R = maxPoints(I, u, 50);

D.15.10.5 maxPointsProb

Procedure from library `maxlike.lib` (see [Section D.15.10 \[maxlike.lib\]](#), page 2477).

- Usage:** `maxPointsProb(I,u,prec [, "nodisplay"])`; ideal `I`, intvec `u`, int `prec` `I` represents the algebraic statistical model, `u` is the data vector under consideration, and `prec` is the precision to be used in the computations
- Return:** ring: a complex ring `R` in which you can find the following two lists: - `MPOINTS`, points in which the loglikelihood function has a local maximum, - `LHESSIANS`, the (modified) Hessians at those points, and - `VALS`, the resulting probability distributions (that is, the values of the polynomials given by `I` at the points in `MPOINTS`). Also prints out the points in `MPOINTS`, unless a fourth argument is given.
- Note:** Does not compute the likelihood ideal via elimination, but rather computes the critical points by projection.

Example:

```
LIB "maxlike.lib";
ring r = 0,(x,y),dp;
poly pA = -10x+2y+25;
poly pC = 8x-y+25;
poly pG = 11x-2y+25;
poly pT = -9x+y+25;
intvec u = 10,14,15,10;
ideal I = pA,pC,pG,pT;
def R = maxPointsProb(I, u, 50);

D.15.11 modfinduni.lib

Library: modfinduni.lib

Purpose: finduni using modular methods

Authors: H. Schoenemann hannes@mathematik.uni-kl.de

Overview: parallel version of finduni via modular.lib

Procedures:

D.15.11.1 modFinduni

Procedure from library `modfinduni.lib` (see [Section D.15.11 \[modfinduni.lib\]](#), page 2482).

Usage: modFinduni(I); I ideal

Return:

Note: The procedure computes a standard basis of I (over the rational numbers) by using modular methods.

See also: [Section D.2.6.1 \[modular\]](#), page 884.

D.15.12 modwalk.lib

Library: modwalk.lib

Purpose: Groebner basis conversion

Authors: S. Oberfranz oberfran@mathematik.uni-kl.de

Overview: A library for converting Groebner bases of an ideal in the polynomial ring over the rational numbers using modular methods. The procedures are inspired by the following paper:

Elizabeth A. Arnold: Modular algorithms for computing Groebner bases. *Journal of Symbolic Computation* 35, 403-419 (2003).

Procedures: See also: [Section D.4.10 \[grwalk.lib\]](#), page 1089; [Section D.15.18 \[rwalk.lib\]](#), page 2583; [Section D.15.24 \[swalk.lib\]](#), page 2601.

D.15.12.1 modWalk

Procedure from library `modwalk.lib` (see [Section D.15.12 \[modwalk.lib\]](#), page 2482).

Return: a standard basis of I

Note: The procedure computes a standard basis of I (over the rational numbers) by using modular methods.

Example:

```

LIB "modwalk.lib";
ring R1 = 0, (x,y,z,t), dp;
ideal I = 3x3+x2+1, 11y5+y3+2, 5z4+z2+4;
I = std(I);
ring R2 = 0, (x,y,z,t), lp;
ideal I = fetch(R1, I);
ideal J = modWalk(I);
J;
⇒ J[1]=x3+1/3x2+1/3
⇒ J[2]=z4+1/5z2+4/5
⇒ J[3]=y5+1/11y3+2/11
ring S1 = 0, (a,b,c,d), Dp;
ideal I = 5b2, ac2+9d3+3a2+5b, 2a2c+7abd+bcd+4a2, 2ad2+6b2d+7c3+8ad+4c;
I = std(I);
ring S2 = 0, (c,d,b,a), lp;
ideal I = fetch(S1,I);
// I is assumed to be a Dp-Groebner basis.
// We compute a lp-Groebner basis.
ideal J = modWalk(I,"Dp");
J;

See also: [Section D.2.6.1 \[modular\]](#), [page 884](#).

D.15.12.2 modrWalk

Procedure from library `modwalk.lib` (see [Section D.15.12 \[modwalk.lib\]](#), [page 2482](#)).

Return: a standard basis of I

Note: The procedure computes a standard basis of I (over the rational numbers) by using modular methods.

Example:

```

LIB "modwalk.lib";
ring R1 = 0, (x,y,z,t), dp;
ideal I = 3x3+x2+1, 11y5+y3+2, 5z4+z2+4;
I = std(I);
ring R2 = 0, (x,y,z,t), lp;
ideal I = fetch(R1, I);
int radius = 2;
ideal J = modrWalk(I,radius);
J;
⇒ J[1]=x3+1/3x2+1/3
⇒ J[2]=z4+1/5z2+4/5
⇒ J[3]=y5+1/11y3+2/11
ring S1 = 0, (a,b,c,d), Dp;
ideal I = 5b2, ac2+9d3+3a2+5b, 2a2c+7abd+bcd+4a2, 2ad2+6b2d+7c3+8ad+4c;
I = std(I);
ring S2 = 0, (c,d,b,a), lp;
ideal I = fetch(S1,I);
// I is assumed to be a Dp-Groebner basis.
// We compute a lp-Groebner basis.
ideal J = modrWalk(I,radius,"Dp");
J;

See also: [Section D.2.6.1 \[modular\]](#), page 884.

D.15.12.3 modfWalk

Procedure from library `modwalk.lib` (see [Section D.15.12 \[modwalk.lib\]](#), page 2482).

Return: a standard basis of I

Note: The procedure computes a standard basis of I (over the rational numbers) by using modular methods.

Example:

```

LIB "modwalk.lib";
ring R1 = 0, (x,y,z,t), dp;
ideal I = 3x3+x2+1, 11y5+y3+2, 5z4+z2+4;
I = std(I);
ring R2 = 0, (x,y,z,t), lp;
ideal I = fetch(R1, I);
ideal J = modfWalk(I);
J;

See also: [Section D.2.6.1 \[modular\]](#), page 884.

D.15.12.4 modfrWalk

Procedure from library `modwalk.lib` (see [Section D.15.12 \[modwalk.lib\]](#), page 2482).

Return: a standard basis of I

Note: The procedure computes a standard basis of I (over the rational numbers) by using modular methods.

Example:

```
LIB "modwalk.lib";
ring R1 = 0, (x,y,z,t), dp;
ideal I = 3x3+x2+1, 11y5+y3+2, 5z4+z2+4;
I = std(I);
ring R2 = 0, (x,y,z,t), lp;
ideal I = fetch(R1, I);
int radius = 2;
ideal J = modfrWalk(I,radius);
J;
⇒ J[1]=z4+1/5z2+4/5
⇒ J[2]=y5+1/11y3+2/11
⇒ J[3]=x3+1/3x2+1/3
ring S1 = 0, (a,b,c,d), Dp;
ideal I = 5b2, ac2+9d3+3a2+5b, 2a2c+7abd+bcd+4a2, 2ad2+6b2d+7c3+8ad+4c;
I = std(I);
ring S2 = 0, (c,d,b,a), lp;
ideal I = fetch(S1,I);
// I is assumed to be a Dp-Groebner basis.
// We compute a lp-Groebner basis.
ideal J = modfrWalk(I,radius,"Dp");
J;

D.15.13 multigrading_lib

Todos/Issues:

See <http://code.google.com/p/convex-singular/wiki/Multigrading>

Library: multigrading.lib

Purpose: Multigraded Rings

Authors: Benjamin Bechtold, benjamin.bechtold@googlemail.com
 Rene Birkner, rbirkner@math.fu-berlin.de
 Lars Kastner, lkastner@math.fu-berlin.de
 Simon Keicher, keicher@mail.mathematik.uni-tuebingen.de
 Oleksandr Motsak, U@D, where U={motsak}, D={mathematik.uni-kl.de}
 Anna-Lena Winz, anna-lena.winz@math.fu-berlin.de

Overview: This library allows one to virtually add multigradings to Singular: grade multi-variate polynomial rings with arbitrary (fin. gen. Abelian) groups. For more see <http://code.google.com/p/convex-singular/wiki/Multigrading> For theoretical references see:

E. Miller, B. Sturmfels: 'Combinatorial Commutative Algebra' and
 M. Kreuzer, L. Robbiano: 'Computational Commutative Algebra'.

Note: 'multiDegBasis' relies on 4ti2 for computing Hilbert Bases. All groups are finitely generated Abelian

Procedures:

D.15.13.1 setBaseMultigrading

Procedure from library multigrading.lib (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: setBaseMultigrading(M[, G]); M is an integer matrix, G is a group (or lattice)

Purpose: attaches weights of variables and grading group to the basering.

Note: M encodes the weights of variables column-wise.

Return: nothing

Example:

```

LIB "multigrading.lib";
ring R = 0, (x, y, z), dp;
// Weights of variables
intmat M[3][3] =
1, 0, 0,
0, 1, 0,
0, 0, 1;
// GradingGroup:
intmat L[3][2] =
1, 1,
1, 3,
1, 5;
// attaches M & L to R (==basing):
setBaseMultigrading(M, L); // Grading:  $Z^3/L$ 
// Weights are accessible via "getVariableWeights()":
getVariableWeights();
⇒ 1,0,0,
⇒ 0,1,0,
⇒ 0,0,1
// Test all possible usages:
(getVariableWeights() == M) && (getVariableWeights(R) == M) && (getVariableWeights(basing) == M)
⇒ 1
// Grading group is accessible via "getLattice()":
getLattice();
⇒ 1,1,
⇒ 1,3,
⇒ 1,5
// Test all possible usages:
(getLattice() == L) && (getLattice(R) == L) && (getLattice(basing) == L);
⇒ 1
// And its hermite NF via getLattice("hermite"):
getLattice("hermite");
⇒ 1,0,
⇒ 1,2,
⇒ 1,4
// Test all possible usages:
intmat H = hermiteNormalForm(L);
(getLattice("hermite") == H) && (getLattice(R, "hermite") == H) && (getLattice(basing, "hermite") == H)
⇒ 1
kill L, M;
// ----- isomorphic multigrading ----- //
// Weights of variables
intmat M[2][3] =
1, -2, 1,
1, 1, 0;
// Torsion:
intmat L[2][1] =
0,
2;
// attaches M & L to R (==basing):
setBaseMultigrading(M, L); // Grading:  $Z + (Z/2Z)$ 
// Weights are accessible via "getVariableWeights()":

```

```

getVariableWeights() == M;
↳ 1
// Torsion is accessible via "getLattice()":
getLattice() == L;
↳ 1
kill L, M;
// ----- extreme case ----- //
// Weights of variables
intmat M[1][3] =
1, -1, 10;
// Torsion:
intmat L[1][1] =
0;
// attaches M & L to R (==basing):
setBaseMultigrading(M); // Grading:  $Z^3$ 
// Weights are accessible via "getVariableWeights()":
getVariableWeights() == M;
↳ 1
// Torsion is accessible via "getLattice()":
getLattice() == L;
↳ 1

```

D.15.13.2 getVariableWeights

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `getVariableWeights([R])`

Purpose: get associated multigrading matrix for the basering [or R]

Return: intmat, matrix of multidegrees of variables

Example:

```

LIB "multigrading.lib";
ring R = 0, (x, y, z), dp;
// Weights of variables
intmat M[3][3] =
1, 0, 0,
0, 1, 0,
0, 0, 1;
// Grading group:
intmat L[3][2] =
1, 1,
1, 3,
1, 5;
// attaches M & L to R (==basing):
setBaseMultigrading(M, L); // Grading:  $Z^3/L$ 
// Weights are accessible via "getVariableWeights()":
getVariableWeights() == M;
↳ 1
kill L, M;
// ----- isomorphic multigrading ----- //
// Weights of variables
intmat M[2][3] =
1, -2, 1,

```

```

1, 1, 0;
// Grading group:
intmat L[2][1] =
0,
2;
// attaches M & L to R (==basing):
setBaseMultigrading(M, L); // Grading:  $Z + (Z/2Z)$ 
// Weights are accessible via "getVariableWeights()":
getVariableWeights() == M;
↪ 1
kill L, M;
// ----- extreme case ----- //
// Weights of variables
intmat M[1][3] =
1, -1, 10;
// Grading group:
intmat L[1][1] =
0;
// attaches M & L to R (==basing):
setBaseMultigrading(M); // Grading:  $Z^3$ 
// Weights are accessible via "getVariableWeights()":
getVariableWeights() == M;
↪ 1

```

D.15.13.3 getGradingGroup

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `getGradingGroup([R])`

Purpose: get associated grading group

Return: group, the grading group

Example:

```

LIB "multigrading.lib";
ring R = 0, (x, y, z), dp;
// Weights of variables
intmat M[3][3] =
1, 0, 0,
0, 1, 0,
0, 0, 1;
// Torsion:
intmat L[3][2] =
1, 1,
1, 3,
1, 5;
// attaches M & L to R (==basing):
setBaseMultigrading(M, L); // Grading:  $Z^3/L$ 
def G = getGradingGroup();
printGroup( G );
↪ Generators:
↪      1      0      0
↪      0      1      0
↪      0      0      1

```

```

↳ Relations:
↳      1      1
↳      1      3
↳      1      5
G[1] == M; G[2] == L;
↳ 1
↳ 1
kill L, M, G;
// ----- isomorphic multigrading ----- //
// Weights of variables
intmat M[2][3] =
1, -2, 1,
1, 1, 0;
// Torsion:
intmat L[2][1] =
0,
2;
// attaches M & L to R (==basing):
setBaseMultigrading(M, L); // Grading:  $\mathbb{Z} + (\mathbb{Z}/2\mathbb{Z})$ 
def G = getGradingGroup();
printGroup( G );
↳ Generators:
↳      1      -2      1
↳      1      1      0
↳ Relations:
↳      0
↳      2
G[1] == M; G[2] == L;
↳ 1
↳ 1
kill L, M, G;
// ----- extreme case ----- //
// Weights of variables
intmat M[1][3] =
1, -1, 10;
// Torsion:
intmat L[1][1] =
0;
// attaches M & L to R (==basing):
setBaseMultigrading(M); // Grading:  $\mathbb{Z}^3$ 
def G = getGradingGroup();
printGroup( G );
↳ Generators:
↳      1      -1      10
↳ Relations:
↳      0
G[1] == M; G[2] == L;
↳ 1
↳ 1
kill L, M, G;

```

D.15.13.4 getLattice

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `getLattice([R[,opt]])`

Purpose: get associated grading group matrix, i.e. generators (cols) of the grading group

Return: `intmat`, the grading group matrix, or
its hermite normal form if an optional argument (`"hermiteNormalForm"`) is given or
smith normal form if an optional argument (`"smith"`) is given

Example:

```
LIB "multigrading.lib";
ring R = 0, (x, y, z), dp;
// Weights of variables
intmat M[3][3] =
1, 0, 0,
0, 1, 0,
0, 0, 1;
// Torsion:
intmat L[3][2] =
1, 1,
1, 3,
1, 5;
// attaches M & L to R (==basing):
setBaseMultigrading(M, L); // Grading:  $Z^3/L$ 
// Torsion is accessible via "getLattice()":
getLattice() == L;
⇒ 1
// its hermite NF:
print(getLattice("hermite"));
⇒      1      0
⇒      1      2
⇒      1      4
kill L, M;
// ----- isomorphic multigrading ----- //
// Weights of variables
intmat M[2][3] =
1, -2, 1,
1, 1, 0;
// Torsion:
intmat L[2][1] =
0,
2;
// attaches M & L to R (==basing):
setBaseMultigrading(M, L); // Grading:  $Z + (Z/2Z)$ 
// Torsion is accessible via "getLattice()":
getLattice() == L;
⇒ 1
// its hermite NF:
print(getLattice("hermite"));
⇒      0
⇒      2
kill L, M;
```

```
// ----- extreme case ----- //
// Weights of variables
intmat M[1][3] =
1, -1, 10;
// Torsion:
intmat L[1][1] =
0;
// attaches M & L to R (==basing):
setBaseMultigrading(M); // Grading: Z^3
// Torsion is accessible via "getLattice()":
getLattice() == L;
⇒ 1
// its hermite NF:
print(getLattice("hermite"));
⇒ 0
```

D.15.13.5 createGroup

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `createGroup(S, L)`; S, L are integer matrices

Purpose: create the group of the form $(S+L)/L$, i.e.
S specifies generators, L specifies relations.

Return: group

Example:

```
LIB "multigrading.lib";
intmat S[3][3] =
1, 0, 0,
0, 1, 0,
0, 0, 1;
intmat L[3][2] =
1, 1,
1, 3,
1, 5;
def G = createGroup(S, L); // (S+L)/L
printGroup(G);
⇒ Generators:
⇒      1      0      0
⇒      0      1      0
⇒      0      0      1
⇒ Relations:
⇒      1      1
⇒      1      3
⇒      1      5
kill S, L, G;
////////////////////////////////////
intmat S[2][3] =
1, -2, 1,
1, 1, 0;
intmat L[2][1] =
0,
2;
```

```

def G = createGroup(S, L); // (S+L)/L
printGroup(G);
↳ Generators:
↳      1      -2      1
↳      1      1      0
↳ Relations:
↳      0
↳      2
kill S, L, G;
// ----- extreme case ----- //
intmat S[1][3] =
1, -1, 10;
// Torsion:
intmat L[1][1] =
0;
def G = createGroup(S, L); // (S+L)/L
printGroup(G);
↳ Generators:
↳      1      -1      10
↳ Relations:
↳      0

```

D.15.13.6 createQuotientGroup

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `createGroup(L)`; L is an integer matrix

Purpose: create the group of the form $(I+L)/L$,
where I is the square identity matrix of size $\text{nrows}(L) \times \text{nrows}(L)$

Note: L specifies relations between free generators of $\mathbb{Z}^{\text{nrows}(L)}$

Return: group

Example:

```

LIB "multigrading.lib";
intmat I[3][3] =
1, 0, 0,
0, 1, 0,
0, 0, 1;
intmat L[3][2] =
1, 1,
1, 3,
1, 5;
// The group  $\mathbb{Z}^3 / L$  can be constructed as follows:
// shortcut:
def G = createQuotientGroup(L);
printGroup(G);
↳ Generators:
↳      1      0      0
↳      0      1      0
↳      0      0      1
↳ Relations:
↳      1      1

```

```

⇒      1      3
⇒      1      5
// the general way:
def GG = createGroup(I, L); // (I+L)/L
printGroup(GG);
⇒ Generators:
⇒      1      0      0
⇒      0      1      0
⇒      0      0      1
⇒ Relations:
⇒      1      1
⇒      1      3
⇒      1      5

```

D.15.13.7 createTorsionFreeGroup

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `createTorsionFreeGroup(S)`; S is an integer matrix

Purpose: create the free subgroup generated by S within the free Abelian group of rank `nrows(S)`

Return: group

Example:

```

LIB "multigrading.lib";
// ----- extreme case ----- //
intmat S[1][3] =
1, -1, 10;
// Torsion:
intmat L[1][1] =
0;
// The free subgroup generated by elements of S within Z^1
// can be constructed as follows:
// shortcut:
def G = createTorsionFreeGroup(S);
printGroup(G);
⇒ Generators:
⇒      1      -1      10
⇒ Relations:
⇒      0
// the general way:
def GG = createGroup(S, L); // (S+L)/L
printGroup(GG);
⇒ Generators:
⇒      1      -1      10
⇒ Relations:
⇒      0

```

D.15.13.8 printGroup

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `printGroup(G)`; G is a group

Purpose: prints the group G

Return: nothing

Example:

```
LIB "multigrading.lib";
intmat S[3][3] =
1, 0, 0,
0, 1, 0,
0, 0, 1;
intmat L[3][2] =
1, 1,
1, 3,
1, 5;
def G = createGroup(S, L); // (S+L)/L
printGroup(G);
↳ Generators:
↳      1      0      0
↳      0      1      0
↳      0      0      1
↳ Relations:
↳      1      1
↳      1      3
↳      1      5
```

D.15.13.9 isGroup

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `isGroup(G)`; G a list

Purpose: checks whether G is a valid group

Note: G should be created by `createGroup`
(or `createQuotientGroup`, `createTorsionFreeGroup`)

Return: int, 1 if G is a valid group and 0 otherwise

Example:

```
LIB "multigrading.lib";
intmat S[3][3] =
1, 0, 0,
0, 1, 0,
0, 0, 1;
intmat L[3][2] =
1, 1,
1, 3,
1, 5;
def G = createGroup(S, L); // (S+L)/L
isGroup(G);
↳ 1
printGroup(G);
↳ Generators:
↳      1      0      0
↳      0      1      0
↳      0      0      1
```

```

⇒ Relations:
⇒      1      1

D.15.13.10 isGroupHomomorphism

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `isGoupHomomorphism(L1,L2,A)`; L1 and L2 are groups, A is an integer matrix

Purpose: checks whether A defines a group homomorphism $\phi: L1 \rightarrow L2$

Return: int, 1 if A defines the homomorphism and 0 otherwise

Example:

```

LIB "multigrading.lib";
intmat L1[4][1]=
0,
0,
0,
2;
intmat L2[3][2]=
0, 0,
2, 0,
0, 3;
intmat A[3][4] =
1, 2, 3, 0,
7, 0, 0, 0,
1, 2, 0, 3;
print( A );
⇒      1      2      3      0
⇒      7      0      0      0
⇒      1      2      0      3
isGroupHomomorphism(L1, L2, A);
⇒ 1
intmat B[3][4] =
1, 2, 3, 0,
7, 0, 0, 0,
1, 2, 0, 2;
print( B );
⇒      1      2      3      0
⇒      7      0      0      0
⇒      1      2      0      2
isGroupHomomorphism(L1, L2, B); // Not a homomorphism!
⇒ 0

```

D.15.13.11 isGradedRingHomomorphism

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `isGradedRingHomomorphism(R, f, A)`; ring R, ideal f, group homomorphism A

Purpose: test a multigraded group ring homomorphism defined by a ring map from R to the current ring, given by generators images f and a group homomorphism A between grading groups

Return: int, 1 for TRUE, 0 otherwise

Example:

```
LIB "multigrading.lib";
ring r = 0, (x, y, z), dp;
intmat S1[3][3] =
1, 0, 0,
0, 1, 0,
0, 0, 1;
intmat L1[3][1] =
0,
0,
0;
def G1 = createGroup(S1, L1); // (S1 + L1)/L1
printGroup(G1);
↳ Generators:
↳      1      0      0
↳      0      1      0
↳      0      0      1
↳ Relations:
↳      0
↳      0
↳      0
setBaseMultigrading(S1, L1); // to change...
ring R = 0, (a, b, c), dp;
intmat S2[2][3] =
1, 0,
0, 1;
intmat L2[2][1] =
0,
2;
def G2 = createGroup(S2, L2);
printGroup(G2);
↳ Generators:
↳      1      0      0
↳      1      0      0
↳ Relations:
↳      0
↳      2
setBaseMultigrading(S2, L2); // to change...
map F = r, a, b, c;
intmat A[nrows(L2)][nrows(L1)] =
1, 0, 0,
3, 2, -6;
// graded ring homomorphism is given by (compatible):
print(F);
↳ F[1]=a
↳ F[2]=b
↳ F[3]=c
print(A);
↳      1      0      0
↳      3      2     -6
isGradedRingHomomorphism(r, ideal(F), A);
```

```

⇒ 1
def h = createGradedRingHomomorphism(r, ideal(F), A);
print(h);
⇒ [1]:
⇒ // coefficients: QQ

print(B);
⇒      1      1      1
⇒      0      0      0
isGradedRingHomomorphism(r, ideal(F), B); // FALSE: there is no such homomorphism!
⇒ 0
// Therefore: the following command should return an error
// createGradedRingHomomorphism(r, ideal(F), B);

```

D.15.13.12 createGradedRingHomomorphism

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `createGradedRingHomomorphism(R, f, A);` ring R , ideal f , group homomorphism A

Purpose: create a multigraded group ring homomorphism defined by a ring map from R to the current ring, given by generators images f and a group homomorphism A between grading groups

Return: graded ring homomorphism

Example:

```

LIB "multigrading.lib";
ring r = 0, (x, y, z), dp;
intmat S1[3][3] =
1, 0, 0,
0, 1, 0,
0, 0, 1;
intmat L1[3][1] =
0,
0,
0;
def G1 = createGroup(S1, L1); // (S1 + L1)/L1
printGroup(G1);
⇒ Generators:
⇒      1      0      0

⇒ //      block 1 : ordering dp
⇒ //      : names    x y z
⇒ //      block 2 : ordering C
⇒ [2]:
⇒ _[1]=a
⇒ _[2]=b
⇒ _[3]=c
⇒ [3]:
⇒ 1,0,0,
⇒ 3,2,-6

```

D.15.13.13 setModuleGrading

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `setModuleGrading(m, G)`, `m` module/vector, `G` intmat

Purpose: attaches the multiweights of free module generators to 'm'

Warning: The method does not verify whether the multigrading makes the module/vector homogeneous. One can do that using `isHomogeneous(m)`.

Example:

```
LIB "multigrading.lib";
ring R = 0, (x,y), dp;
intmat M[2][2]=
1, 1,
0, 2;
intmat T[2][5]=
1, 2, 3, 4, 0,
0, 10, 20, 30, 1;
setBaseMultigrading(M, T);
ideal I = x, y, xy^5;
intmat V = multiDeg(I);
// V == M; modulo T
print(V);
↳      1      1      10
↳      0      2      10
module S = syz(I);
S = setModuleGrading(S, V);
getModuleGrading(S) == V;
↳ 1
print(S);
↳ -y,x4y5,
↳ x, 0,
↳ 0, -1
vector v = getGradedGenerator(S, 1);
getModuleGrading(v) == V;
↳ 1
print( multiDeg(v) );
↳ 2,
↳ 2
isHomogeneous(S);
↳ 1
print( multiDeg(S) );
↳      2      10
↳      2      10
```

D.15.13.14 getModuleGrading

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `getModuleGrading(m)`, 'm' module/vector

Return: integer matrix of the multiweights of free module generators attached to 'm'

Example:

```

LIB "multigrading.lib";
ring R = 0, (x,y), dp;
intmat M[2][2]=
1, 1,
0, 2;
intmat T[2][5]=
1, 2, 3, 4, 0,
0, 10, 20, 30, 1;
setBaseMultigrading(M, T);
ideal I = x, y, xy^5;
isHomogeneous(I);
↪ 1
intmat V = multiDeg(I); print(V);
↪      1      1      10
↪      0      2      10
module S = syz(I); print(S);
↪ -y,x4y5,
↪ x, 0,
↪ 0, -1
S = setModuleGrading(S, V);
getModuleGrading(S) == V;
↪ 1
vector v = getGradedGenerator(S, 1);
getModuleGrading(v) == V;
↪ 1
isHomogeneous(v);
↪ 1
print( multiDeg(v) );
↪ 2,
↪ 2
isHomogeneous(S);
↪ 1
print( multiDeg(S) );
↪      2      10
↪      2      10

```

D.15.13.15 isSublattice

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `isSublattice(L, S)`; L, S are of type `intmat`

Purpose: checks whether the lattice created by L is a sublattice of the lattice created by S.
The procedure checks whether each generator of L is contained in S.

Return: integer, 0 if false, 1 if true

Example:

```

LIB "multigrading.lib";
//ring R = 0,(x,y),dp;
intmat S2[3][3]=
0, 2, 3,
0, 1, 1,

```

```

3, 0, 2;
intmat S1[3][2]=
0, 6,
0, 2,
3, 4;
isSublattice(S1,S2); // Yes!
⇒ 1
intmat S3[3][1] =
0,
0,
1;
not(isSublattice(S3,S2)); // Yes!
⇒ 1

```

D.15.13.16 imageLattice

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `imageLattice(Q,L)`; Q and L are of type `intmat`

Purpose: compute an integral basis for the image of the lattice L under the homomorphism of lattices Q.

Return: `intmat`

Example:

```

LIB "multigrading.lib";
intmat Q[2][3] =
1,2,3,
3,2,1;
intmat L[3][2] =
1,4,
2,5,
3,6;
// should be a 2x2 matrix with columns
// [2,-14], [0,36]
imageLattice(Q,L);
⇒ 2,0,
⇒ 22,36

```

D.15.13.17 intRank

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `intRank(A)`; `intmat` A

Purpose: compute the rank of the integral matrix A by computing a hermite normalform.

Returns: `int`

Example:

```

LIB "multigrading.lib";
intmat A[3][4] =
1,0,1,0,
1,2,0,0,

```

```

0,0,0,0;
int r = intRank(A);
print(A);
↳      1      0      1      0
↳      1      2      0      0
↳      0      0      0      0
print(r); // Should be 2
↳ 2
// another example
intmat B[2][2] =
1,2,
1,2;
int d = intRank(B);
print(B);
↳      1      2
↳      1      2
print(d); // Should be 1
↳ 1
kill A, B, r, d;

```

D.15.13.18 kernelLattice

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `kernelLattice(P); intmat P`

Purpose: compute a integral basis for the kernel of the
 homomorphism of lattices defined by the intmat P.

Returns: intmat

Example:

```

LIB "multigrading.lib";
intmat LL[3][4] =
1,4,7,10,
2,5,8,11,
3,6,9,12;
// should be a 4x2 matrix whose columns
// generate the same lattice as [-1,2,-1,0],[2,-3,0,1]
intmat B = kernelLattice(LL);
print(B);
↳      -1      2
↳       2     -3
↳      -1      0
↳       0      1
// another example
intmat C[2][4] =
1,0,2,0,
0,1,2,0;
// should result in a matrix whose
// columns create the same lattice as
// [-2,-2,1,0], [0,0,0,1]
intmat D = kernelLattice(C);
print(D);
↳      -2      0

```

```

⇒      -2      0
⇒       1      0
⇒       0      1
kill B;

```

D.15.13.19 latticeBasis

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `latticeBasis(B); intmat B`

Purpose: compute an integral basis for the lattice defined by the columns of B.

Returns: `intmat`

Example:

```

LIB "multigrading.lib";
intmat L[3][3] =
1,4,8,
2,5,10,
3,6,12;
intmat B = latticeBasis(L);
print(B); // should result in a matrix whose columns generate the same lattice as [
⇒       1      0
⇒       2      3
⇒       3      6
// another example
intmat C[2][4] =
1,1,2,0,
2,3,4,0;
// should result in a matrix whose
// columns create the same lattice as
// [0,1],[1,0]
intmat D = latticeBasis(C);
print(D);
⇒       1      0
⇒       0      1
kill B,L;

```

D.15.13.20 preimageLattice

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `preimageLattice(P, B); intmat P, intmat B`

Purpose: compute an integral basis for the preimage of B under the homomorphism of lattices defined by the `intmat` P.

Returns: `intmat`

Example:

```

LIB "multigrading.lib";
intmat P[2][3] =
2,6,10,
4,8,12;
intmat B[2][1] =
1,

```

```

0;
// should be a (3x2)-matrix with columns e.g. [1,1,-1] and [0,3,-2] (the generated lat
print(preimageLattice(P,B));
↳      1      0
↳      1      3
↳     -1     -2
// another example
intmat W[3][3] =
1,0,0,
0,1,1,
0,2,0;
intmat Z[3][2] =
1,0,
0,1,
0,0;
// should be a (3x2)-matrix with columns e.g. [1,0,0] and [0,0,-1] (the generated lat
print(preimageLattice(W,Z));
↳      1      0
↳      0      0
↳      0      1

```

D.15.13.21 projectLattice

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `projectLattice(B); intmat B`

Purpose: A set of vectors in $\mathbb{Z}\mathbb{Z}^m$ is given as the columns of B. Then this function provides a linear map $\mathbb{Z}\mathbb{Z}^m \rightarrow \mathbb{Z}\mathbb{Z}^n$ having the primitive span of B its kernel.

Returns: `intmat`

Example:

```

LIB "multigrading.lib";
intmat B[4][2] =
1,5,
2,6,
3,7,
4,8;
// should result in a (2x4)-matrix such that the corresponding lattice is created by
// [-1, 2], [-2, 3], [-1, 0] and [0, 1]
print(projectLattice(B));
↳     -1      2     -1      0
↳      2     -3      0      1
// another example
intmat BB[4][2] =
1,0,
0,1,
0,0,
0,0;
// should result in a (2x4)-matrix such that the corresponding lattice is created by
// [0,0],[0,0],[1,0],[0,1]
print(projectLattice(BB));
↳      0      0      1      0
↳      0      0      0      1

```

```
// another example
intmat BBB[3][4] =
1,0,1,2,
1,1,0,0,
3,0,0,3;
// should result in the (1x3)-matrix that consists of just zeros
print(projectLattice(BBB));
⇒      0      0      0
```

D.15.13.22 intersectLattices

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `intersectLattices(A, B);` intmat A, intmat B

Purpose: compute an integral basis for the intersection of the lattices A and B.

Returns: intmat

Example:

```
LIB "multigrading.lib";
intmat A[3][2] =
1,4,
2,5,
3,6;
intmat B[3][2] =
6,9,
7,10,
8,11;
// should result in a (3x2)-matrix with columns
// e.g. [0, 3, 6], [-3, 0, 3] (the lattice should be the same)
print(intersectLattices(A,B));
⇒      3      0
⇒      0      3
⇒     -3      6
// another example
intmat C[2][3] =
1,0,0,
3,2,5;
intmat D[2][3] =
4,5,0,
0,5,0;
// should result in a (3x2)-matrix whose columns generate the
// same lattice as [1,5], [0, 20]
print(intersectLattices(C,D));
⇒      1      0
⇒      5     20
```

D.15.13.23 isIntegralSurjective

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Purpose: test whether the given linear map P of lattices is surjective.

Returns: int, where 0 is false and 1 is true.

Example:

```

LIB "multigrading.lib";
intmat A[2][3] =
1,3,5,
2,4,6;
// should be 0
int b = isIntegralSurjective(A);
print(b);
↪ 0
// another example
intmat B[2][3] =
1,1,5,
2,3,6;
// should be 1
int c = isIntegralSurjective(B);
print(c);
↪ 1
kill A, b, B, c;

```

D.15.13.24 isPrimitiveSublattice

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Purpose: check whether the given set of integral vectors in \mathbb{Z}^m , i.e. the columns of A , generate a primitive sublattice in \mathbb{Z}^m (a direct summand of \mathbb{Z}^m).

Returns: int, where 0 is false and 1 is true.

Example:

```

LIB "multigrading.lib";
intmat A[3][2] =
1,4,
2,5,
3,6;
// should be 0
int b = isPrimitiveSublattice(A);
print(b);
↪ 0
// another example
intmat B[2][2] =
1,0,
0,1;
// should be 1
int c = isPrimitiveSublattice(B);
print(c);
↪ 1
kill A, b, B, c;

```

D.15.13.25 intInverse

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Purpose: compute the integral inverse of the intmat A .
If $\det(A)$ is neither 1 nor -1 an error is returned.

Returns: intmat

Example:

```
LIB "multigrading.lib";
intmat A[3][3] =
1,1,3,
3,2,0,
0,0,1;
intmat B = intInverse(A);
// should be the unit matrix
print(A * B);
↪      1      0      0
↪      0      1      0
↪      0      0      1
// another example
intmat C[2][2] =
2,1,
3,2;
intmat D = intInverse(C);
// should be the unit matrix
print(C * D);
↪      1      0
↪      0      1
kill A, B, C, D;
```

D.15.13.26 integralSection

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Purpose: for a given linear surjective map P of lattices
this procedure returns an integral section of P .

Returns: intmat

Example:

```
LIB "multigrading.lib";
intmat P[2][4] =
1,3,4,6,
2,4,5,7;
// should be a matrix with two columns
// for example: [-2, 1, 0, 0], [3, -3, 0, 1]
intmat U = integralSection(P);
print(U);
↪      -1      1
↪      -2      1
↪       2     -1
↪       0      0
print(P * U);
↪       1      0
↪       0      1
kill U;
```

D.15.13.27 primitiveSpan

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Purpose: compute an integral basis for the minimal primitive sublattice that contains the given vectors, i.e. the columns of V .

Returns: int, where 0 is false and 1 is true.

Example:

```
LIB "multigrading.lib";
intmat V[3][2] =
1,4,
2,5,
3,6;
// should return a (3x2)-matrix whose columns
// generate the same lattice as [1, 2, 3] and [0, 1, 2]
intmat R = primitiveSpan(V);
print(R);
↪      1      0
↪      2      1
↪      3      2
// another example
intmat W[2][2] =
1,0,
0,1;
// should return a (2x2)-matrix whose columns
// generate the same lattice as [1, 0] and [0, 1]
intmat S = primitiveSpan(W);
print(S);
↪      1      0
↪      0      1
kill V, R, S, W;
```

D.15.13.28 factorgroup

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `factorgroup(G,H);` list G , list H

Purpose: returns a representation of the factor group $G \bmod H$ using the first isomorphism thm

Returns: list

Example:

```
LIB "multigrading.lib";
intmat S1[2][2] =
1,0,
0,1;
intmat L1[2][1] =
2,
0;
intmat S2[2][1] =
1,
0;
intmat L2[2][1] =
2,
0;
list G = createGroup(S1,L1);
list H = createGroup(S2,L2);
```

```

list N = factorgroup(G,H);
print(N);
⇒ [1]:
⇒ 1,0,
⇒ 0,1
⇒ [2]:
⇒ 2,1,
⇒ 0,0
kill G,H,N,S1,L1,S2,L2;

```

D.15.13.29 productgroup

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `productgroup(G,H);` list G, list H

Purpose: Returns a representation of the group $G \times H$

Returns: list

Example:

```

LIB "multigrading.lib";
intmat S1[2][2] =
1,0,
0,1;
intmat L1[2][1] =
2,
0;
intmat S2[2][2] =
1,0,
0,2;
intmat L2[2][1] =
0,
3;
list G = createGroup(S1,L1);
list H = createGroup(S2,L2);
list N = productgroup(G,H);
print(N);
⇒ [1]:
⇒ 1,0,0,0,
⇒ 0,1,0,0,
⇒ 0,0,1,0,
⇒ 0,0,0,2
⇒ [2]:
⇒ 2,0,
⇒ 0,0,
⇒ 0,0,
⇒ 0,3
kill G,H,N,S1,L1,S2,L2;

```

D.15.13.30 multiDeg

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `multiDeg(A);` polynomial/vector/ideal/module A

Purpose: compute multidegree

Example:

```
LIB "multigrading.lib";
ring r = 0,(x, y), dp;
intmat A[2][2] = 1, 0, 0, 1;
print(A);
↳      1      0
↳      0      1
intmat Ta[2][1] = 0, 3;
print(Ta);
↳      0
↳      3
// attrib(A, "gradingGroup", Ta); // to think about
// "poly:";
setBaseMultigrading(A);
multiDeg( x*x, A );
↳ 2,0
multiDeg( y*y*y, A );
↳ 0,3
setBaseMultigrading(A, Ta);
multiDeg( x*x*y );
↳ 2,1
multiDeg( y*y*y*x );
↳ 1,3
multiDeg( x*y + x + 1 );
↳ 1,1
multiDegPartition(x*y + x + 1);
↳ _[1]=xy
↳ _[2]=x
↳ _[3]=1
print ( multiDeg(0) );
↳ 0,
↳ 0
poly zero = 0;
print ( multiDeg(zero) );
↳ 0,
↳ 0
// "ideal:";
ideal I = y*x*x, x*y*y*y;
print( multiDeg(I) );
↳      2      1
↳      1      3
print ( multiDeg(ideal(0)) );
↳ 0,
↳ 0
print ( multiDeg(ideal(0,0,0)) );
↳      0      0      0
↳      0      0      0
// "vectors:";
intmat B[2][2] = 0, 1, 1, 0;
print(B);
↳      0      1
```

```

↳      1      0
multiDeg( setModuleGrading(y*y*y*gen(2), B ));
↳ 1,3
multiDeg( setModuleGrading(x*x*gen(1), B ));
↳ 2,1
vector V = x*gen(1) + y*gen(2);
V = setModuleGrading(V, B);
multiDeg( V );
↳ 1,1
vector v1 = setModuleGrading([0, 0, 0], B);
print( multiDeg( v1 ) );
↳ 0,
↳ 0
vector v2 = setModuleGrading([0], B);
print( multiDeg( v2 ) );
↳ 0,
↳ 0
// "module:";
module D = x*gen(1), y*gen(2);
D;
↳ D[1]=x*gen(1)
↳ D[2]=y*gen(2)
D = setModuleGrading(D, B);
print( multiDeg( D ) );
↳      1      1
↳      1      1
module DD = [0, 0],[0, 0, 0];
DD = setModuleGrading(DD, B);
print( multiDeg( DD ) );
↳      0      0
↳      0      0
module DDD = [0, 0];
DDD = setModuleGrading(DDD, B);
print( multiDeg( DDD ) );
↳ 0,
↳ 0

```

D.15.13.31 multiDegBasis

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `multiDegBasis(d), multidegree: intvec d`

Assume: current ring is multigraded, monomial ordering is global

Purpose: compute all monomials of multidegree d

Example:

```

LIB "multigrading.lib";
ring R = 0, (x, y), dp;
intmat g1[2][2]=1,0,0,1;
intmat l[2][1]=2,0;
intmat g2[2][2]=1,1,1,1;
intvec v1=4,0;
intvec v2=4,4;

```

```

intmat g3[1][2]=1,1;
setBaseMultigrading(g3);
intvec v3=4:1;
v3;
↳ 4
multiDegBasis(v3);
↳ _[1]=x4
↳ _[2]=y4
↳ _[3]=xy3
↳ _[4]=x2y2
↳ _[5]=x3y
setBaseMultigrading(g1,1);
multiDegBasis(v1);
↳ _[1]=1
setBaseMultigrading(g2);
multiDegBasis(v2);
↳ _[1]=y4
↳ _[2]=x4
↳ _[3]=x3y
↳ _[4]=x2y2
↳ _[5]=xy3
intmat M[2][2] = 1, -1, -1, 1;
intvec d = -2, 2;
setBaseMultigrading(M);
multiDegBasis(d);
↳ _[1]=y2
attrib(_, "ZeroPart");
↳ _[1]=xy
kill R, M, d;
ring R = 0, (x, y, z), dp;
intmat M[2][3] = 1, -2, 1,      1, 1, 0;
intmat L[2][1] = 0, 2;
intvec d = 4, 1;
setBaseMultigrading(M, L);
multiDegBasis(d);
↳ _[1]=x3z
↳ _[2]=x6y
↳ _[3]=yz6
↳ _[4]=xz3
attrib(_, "ZeroPart");
↳ _[1]=xyz
↳ _[2]=x4y2
↳ _[3]=y2z4
kill R, M, d;
ring R = 0, (x, y, z), dp;
qring Q = std(ideal( y^6+ x*y^3*z-x^2*z^2 ));
intmat M[2][3] = 1, 1, 2,      2, 1, 1;
// intmat T[2][1] = 0, 2;
setBaseMultigrading(M); // BUG????
intvec d = 6, 6;
multiDegBasis(d);
↳ _[1]=x2z2
↳ _[2]=xy3z

```

```

attrib(_, "ZeroPart");
⇨ _[1]=0
kill R, Q, M, d;
ring R = 0, (x, y, z), dp;
qring Q = std(ideal( x*z^3 - y *z^6, x*y*z - x^4*y^2 ));
intmat M[2][3] = 1, -2, 1,      1, 1, 0;
intmat T[2][1] = 0, 2;
intvec d = 4, 1;
setBaseMultigrading(M, T); // BUG????
multiDegBasis(d);
⇨ _[1]=x3z
⇨ _[2]=x6y
⇨ _[3]=xz3
attrib(_, "ZeroPart");
⇨ _[1]=xyz
⇨ _[2]=y2z4

```

D.15.13.32 multiDegPartition

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `multiDegPartition(def p), p` polynomial/vector

Returns: an ideal/module consisting of multigraded-homogeneous parts of `p`

Example:

```

LIB "multigrading.lib";
ring r = 0,(x,y,z),dp;
intmat g[2][3]=
1,0,1,
0,1,1;
intmat t[2][1]=
-2,
1;
setBaseMultigrading(g,t);
poly f = x10yz+x8y2z-x4z2+y5+x2y2-z2+x17z3-y6;
multiDegPartition(f);
⇨ _[1]=x17z3
⇨ _[2]=x10yz+x8y2z
⇨ _[3]=-y6
⇨ _[4]=-x4z2+y5
⇨ _[5]=x2y2-z2
vector v = xy*gen(1)-x3y2*gen(2)+x4y*gen(3);
intmat B[2][3]=1,-1,-2,0,0,1;
v = setModuleGrading(v,B);
getModuleGrading(v);
⇨ 1,-1,-2,
⇨ 0,0,1
multiDegPartition(v, B);
⇨ _[1]=x4y*gen(3)-x3y2*gen(2)
⇨ _[2]=xy*gen(1)

```

D.15.13.33 isTorsionFree

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: isTorsionFree()

Purpose: Determines whether the multigrading attached to the current ring is free.

Return: boolean, the result of the test

Example:

```
LIB "multigrading.lib";
ring R = 0,(x,y),dp;
intmat M[2][2]=
1,0,
0,1;
intmat T[2][5]=
1, 2, 3, 4, 0,
0,10,20,30, 1;
setBaseMultigrading(M,T);
// Is the resulting group free?
isTorsionFree();
↪ 1
kill R, M, T;
////////////////////////////////////
ring R=0,(x,y,z),dp;
intmat A[3][3] =
1,0,0,
0,1,0,
0,0,1;
intmat B[3][4]=
3,3,3,3,
2,1,3,0,
1,2,0,3;
setBaseMultigrading(A,B);
// Is the resulting group free?
isTorsionFree();
↪ 0
kill R, A, B;
```

D.15.13.34 isPositive

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: isPositive()

Purpose: Computes whether the multigrading of the ring is positive. For computation theorem 8.6 of the Miller/Sturmfels book is used.

Returns: true if the multigrading is positive

Example:

```
LIB "multigrading.lib";
printlevel = 3;
ring r = 0,(x,y),dp;
intmat A[1][2]=-1,1;
setBaseMultigrading(A);
isPositive();
↪ 0
intmat B[1][2]=1,1;
```

```

setBaseMultigrading(B);
isPositive(B);
 $\mapsto$  1

```

D.15.13.35 isZeroElement

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `isZeroElement(d, [T]);` intvec d, group T

Purpose: For a integer vector 'd' representing the multidegree of some polynomial or vector this method computes if the multidegree is contained in the grading group group (either set globally or given as an optional argument), i.e. if it is zero in the multigrading.

Example:

```

LIB "multigrading.lib";
ring r = 0,(x,y,z),dp;
intmat g[2][3]=
1,0,1,
0,1,1;
intmat t[2][1]=
-2,
1;
intmat tt[2][1]=
1,
-1;
setBaseMultigrading(g,t);
poly a = x10yz;
poly b = x8y2z;
poly c = x4z2;
poly d = y5;
poly e = x2y2;
poly f = z2;
intvec v1 = multiDeg(a) - multiDeg(b);
v1;
 $\mapsto$  2,-1
isZeroElement(v1);
 $\mapsto$  1
isZeroElement(v1, tt);
 $\mapsto$  0
intvec v2 = multiDeg(a) - multiDeg(c);
v2;
 $\mapsto$  5,0
isZeroElement(v2);
 $\mapsto$  0
isZeroElement(v2, tt);
 $\mapsto$  0
intvec v3 = multiDeg(e) - multiDeg(f);
v3;
 $\mapsto$  0,0
isZeroElement(v3);
 $\mapsto$  1
isZeroElement(v3, tt);
 $\mapsto$  1

```

```

intvec v4 = multiDeg(c) - multiDeg(d);
v4;
↳ 6,-3
isZeroElement(v4);
↳ 1
isZeroElement(v4, tt);
↳ 0

```

D.15.13.36 areZeroElements

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `areZeroElements(D, [T]);` intmat D, group T

Purpose: For a integer matrix D, considered column-wise as a set of integer vecors representing the multidegree of some polynomial or vector this method checks whether all these multidegrees are contained in the grading group
group (either set globally or given as an optional argument), i.e. if they all are zero in the multigrading.

Example:

```

LIB "multigrading.lib";
ring r = 0,(x,y,z),dp;
intmat S[2][3]=
1,0,1,
0,1,1;
intmat L[2][1]=
2,
2;
setBaseMultigrading(S,L);
poly a = 1;
poly b = xyz;
ideal I = a, b;
print(multiDeg(I));
↳      0      2
↳      0      2
intmat m[5][2]=multiDeg(a),multiDeg(b); m=transpose(m);
print(multiDeg(a));
↳ 0,
↳ 0
print(multiDeg(b));
↳ 2,
↳ 2
print(m);
↳      0      2      0      0      0
↳      0      2      0      0      0
areZeroElements(m);
↳ 1
intmat LL[2][1]=
1,
-1;
areZeroElements(m,LL);
↳ 0

```

D.15.13.37 isHomogeneous

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `isHomogeneous(a[, f]);` a polynomial/vector/ideal/module

Return: boolean, TRUE if a is (multi)homogeneous, and FALSE otherwise

Example:

```
LIB "multigrading.lib";
ring r = 0,(x,y,z),dp;
//Grading and Torsion matrices:
intmat M[3][3] =
1,0,0,
0,1,0,
0,0,1;
intmat T[3][1] =
1,2,3;
setBaseMultigrading(M,T);
attrib(r);
↳ attr:cf_class, type int
↳ attr:global, type int
↳ attr:maxExp, type int
↳ attr:ring_cf, type int
↳ attr:isLetterplaceRing, type int
↳ attr:gradingGroup, type list
↳ attr:mgrad, type intmat
poly f = x-yz;
multiDegPartition(f);
↳ _[1]=-yz
↳ _[2]=x
print(multiDeg(_));
↳      0      1
↳      1      0
↳      1      0
isHomogeneous(f); // f: is not homogeneous
↳ 0
poly g = 1-xy2z3;
isHomogeneous(g); // g: is homogeneous
↳ 1

```

D.15.13.38 equalMultiDeg

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `equalMultiDeg(exp1, exp2[, V]);` intvec exp1, exp2, intmat V

Purpose: Tests if the exponent vectors of two monomials (given by exp1 and exp2) represent the same multidegree.

Note: the integer matrix V encodes multidegrees of module components, if module component is present in exp1 and exp2

Example:

```

LIB "multigrading.lib";
printlevel=3;
ring r = 0,(x,y,z),dp;
intmat g[2][3]=
1,0,1,
0,1,1;
intmat t[2][1]=
-2,
1;
setBaseMultigrading(g,t);
poly a = x10yz;
poly b = x8y2z;
poly c = x4z2;
poly d = y5;
poly e = x2y2;
poly f = z2;
equalMultiDeg(leadexp(a), leadexp(b));
↪ 1
equalMultiDeg(leadexp(a), leadexp(c));
↪ 0
equalMultiDeg(leadexp(a), leadexp(d));
↪ 0
equalMultiDeg(leadexp(a), leadexp(e));
↪ 0
equalMultiDeg(leadexp(a), leadexp(f));
↪ 0
equalMultiDeg(leadexp(b), leadexp(c));
↪ 0
equalMultiDeg(leadexp(b), leadexp(d));
↪ 0
equalMultiDeg(leadexp(b), leadexp(e));
↪ 0

```

```

equalMultiDeg(leadexp(b), leadexp(f));
↳ 0
equalMultiDeg(leadexp(c), leadexp(d));
↳ 1
equalMultiDeg(leadexp(c), leadexp(e));
↳ 0
equalMultiDeg(leadexp(c), leadexp(f));
↳ 0
equalMultiDeg(leadexp(d), leadexp(e));
↳ 0
equalMultiDeg(leadexp(d), leadexp(f));
↳ 0
equalMultiDeg(leadexp(e), leadexp(f));
↳ 1

```

D.15.13.39 multiDegGroebner

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `multiDegGroebner(I)`; I is a poly/vector/ideal/module

Purpose: computes the multigraded standard/groebner basis of I

Note: I must be multigraded homogeneous

Returns: ideal/module, the computed basis

Example:

```

LIB "multigrading.lib";
ring r = 0,(x,y,z,w),dp;
intmat MM[2][4]=
1,1,1,1,
0,1,3,4;
setBaseMultigrading(MM);
module M = ideal( xw-yz, x2z-y3, xz2-y2w, yw2-z3);
intmat v[2][nrows(M)]=
1,
0;
M = setModuleGrading(M, v);
////////////////////////////////////

D.15.13.40 multiDegSyzygy

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `multiDegSyzygy(I)`; I is a ideal or a module

Purpose: computes the multigraded syzygy module of I

Returns: module, the syzygy module of I

Note: generators of I must be multigraded homogeneous

Example:

```
LIB "multigrading.lib";
```

```

ring r = 0,(x,y,z,w),dp;
intmat MM[2][4]=
1,1,1,1,
0,1,3,4;
setBaseMultigrading(MM);
module M = ideal( xw-yz, x2z-y3, xz2-y2w, yw2-z3);
intmat v[2][nrows(M)]=
1,
0;
M = setModuleGrading(M, v);
isHomogeneous(M);
↳ 1
"Multidegrees: "; print(multiDeg(M));
↳ Multidegrees:
↳      3      4      4
↳      4      3      6      9
// Let's compute syzygies!
def S = multiDegSyzygy(M); S;
↳ S[1]=yw*gen(1)-x*gen(4)-z*gen(3)
↳ S[2]=z2*gen(1)-y*gen(4)-w*gen(3)
↳ S[3]=xz*gen(1)+y*gen(3)-w*gen(2)
↳ S[4]=y2*gen(1)+x*gen(3)-z*gen(2)
"Module Units Multigrading: "; print( getModuleGrading(S) );
↳ Module Units Multigrading:
↳      3      4      4      4
↳      4      3      6      9
"Multidegrees: "; print(multiDeg(S));
↳ Multidegrees:
↳      5      5      5      5
↳      9     10      7      6
isHomogeneous(S);
↳ 1

```

D.15.13.41 multiDegModulo

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `multiDegModulo(I);` I, J are ideals or modules

Purpose: computes the multigraded 'modulo' module of I and J

Returns: module, see 'modulo' command

Note: I and J should have the same multigrading, and their
generators must be multigraded homogeneous

Example:

```

LIB "multigrading.lib";
ring r = 0,(x,y,z),dp;
intmat MM[2][3]=
-1,1,1,
0,1,3;
setBaseMultigrading(MM);
ideal h1 = x, y, z;
ideal h2 = x;

```

```

"Multidegrees: "; print(multiDeg(h1));
↳ Multidegrees:
↳      -1      1      1
↳       0      1      3
// Let's compute modulo(h1, h2):
def K = multiDegModulo(h1, h2); K;
↳ K[1]=gen(1)
↳ K[2]=y*gen(3)-z*gen(2)
↳ K[3]=x*gen(2)
↳ K[4]=x*gen(3)
"Module Units Multigrading: "; print( getModuleGrading(K) );
↳ Module Units Multigrading:
↳      -1      1      1
↳       0      1      3
"Multidegrees: "; print(multiDeg(K));
↳ Multidegrees:
↳      -1      2      0      0
↳       0      4      1      3
isHomogeneous(K);
↳ 1

```

D.15.13.42 multiDegResolution

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `multiDegResolution(I,l,[f]);` I is poly/vector/ideal/module; l,f are integers

Purpose: computes the multigraded resolution of I of the length l, or the whole resolution if l is zero. Returns minimal resolution if an optional argument 1 is supplied

Note: input must have multigraded-homogeneous generators.
The returned list is truncated beginning with the first zero differential.

Returns: list, the computed resolution

Example:

```

LIB "multigrading.lib";
ring r = 0,(x,y,z,w),dp;
intmat M[2][4]=
1,1,1,1,
0,1,3,4;
setBaseMultigrading(M);
module m= ideal( xw-yz, x2z-y3, xz2-y2w, yw2-z3);
isHomogeneous(ideal( xw-yz, x2z-y3, xz2-y2w, yw2-z3), "checkGens");
↳ 1
ideal A = xw-yz, x2z-y3, xz2-y2w, yw2-z3;
int j;
for(j=1; j<=ncols(A); j++)
{
multiDegPartition(A[j]);
}
↳ _[1]=-yz+xw
↳ _[1]=-y3+x2z
↳ _[1]=xz2-y2w
↳ _[1]=-z3+yw2

```

```

intmat v[2][1]=
1,
0;
m = setModuleGrading(m, v);
// Let's compute Syzygy!
def S = multiDegSyzygy(m); S;
↳ S[1]=yw*gen(1)-x*gen(4)-z*gen(3)
↳ S[2]=z2*gen(1)-y*gen(4)-w*gen(3)
↳ S[3]=xz*gen(1)+y*gen(3)-w*gen(2)

D.15.13.43 multiDegTensor

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `multiDegTensor(m, n)`, `m, n` modules or matrices.

Purpose: Computes the multigraded tensor product of to multigraded modules.

Return: A module.

Example:

```

LIB "multigrading.lib";
ring r = 0,(x),dp;
intmat g[2][1]=1,1;
setBaseMultigrading(g);
matrix m[5][3]=1,2,3,4,5,6,7,8,9,10,11,12,13,14,15;
matrix n[3][2]=x,x2,x3,x4,x5,x6;
module mm = m;
module nn = n;
intmat gm[2][5]=1,2,3,4,5,0,0,0,0,0;
intmat gn[2][3]=0,0,0,1,2,3;
mm = setModuleGrading(mm, gm);
nn = setModuleGrading(nn, gn);
module mmtnn = multiDegTensor(mm, nn);
print(mmtnn);
⇒ x, x2,0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 2, 0, 0, 3, 0, 0,
⇒ x3,x4,0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 2, 0, 0, 3, 0,
⇒ x5,x6,0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 2, 0, 0, 3,
⇒ 0, 0, x, x2,0, 0, 0, 0, 0, 0, 0, 4, 0, 0, 5, 0, 0, 6, 0, 0,

```

```

⇒ 0, 0, x3,x4,0, 0, 0, 0, 0, 0, 0, 4, 0, 0, 5, 0, 0, 6, 0,

```

D.15.13.44 multiDegTor

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

D.15.13.45 defineHomogeneous

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `defineHomogeneous(f[, G]);` polynomial `f`, integer matrix `G`

Purpose: Yields a matrix which has to be appended to the grading group matrix to make the polynomial `f` homogeneous in the grading by `grad`.

Example:

```

LIB "multigrading.lib";
ring r =0,(x,y,z),dp;
intmat grad[2][3] =
1,0,1,
0,1,1;
setBaseMultigrading(grad);
poly f = x2y3-z5+x-3zx;
intmat M = defineHomogeneous(f);
M;
⇒ 3,0,-1,
⇒ 2,-2,-3
defineHomogeneous(f, grad) == M;
⇒ 1
isHomogeneous(f);
⇒ 0
setBaseMultigrading(grad, M);
isHomogeneous(f);
⇒ 1

```

D.15.13.46 pushForward

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `pushForward(f);`

Purpose: Computes the finest grading of the image ring which makes the map `f` a map of graded rings. The group map between the two grading groups is given by `transpose((Id, 0))`. Pay attention that the group spanned by the columns of the grading group matrix

may not be a subgroup of the grading group. Still all columns are needed to find the correct image of the preimage gradings.

Example:

```
LIB "multigrading.lib";
ring r = 0,(x,y,z),dp;
// Setting degrees for preimage ring.;
intmat grad[3][3] =
1,0,0,
0,1,0,
0,0,1;
setBaseMultigrading(grad);
// grading on r:
getVariableWeights();
⇒ 1,0,0,
⇒ 0,1,0,
⇒ 0,0,1
getLattice();
⇒ 0,0,0
// only for the purpose of this example
if( voice > 1 ){ /*keepring(r);*/ export(r); }
ring R = 0,(a,b),dp;
ideal i = a2-b2+a6-b5+ab3,a7b+b15-ab6+a6b6;
// The quotient ring by this ideal will become our image ring.;
qring Q = std(i);
listvar();
⇒ // Q [0] *ring
⇒ // R [0] ring
⇒ // grad [0] intmat 3 x 3
⇒ // r [0] ring
map f = r,-a2b6+b5+a3b+a2+ab,-a2b7-3a2b5+b4+a,a6-b6-b3+a2; f;
⇒ f[1]=-a2b6+b5+a3b+a2+ab
⇒ f[2]=-a2b7-3a2b5+b4+a
⇒ f[3]=a6-b6-b3+a2
// TODO: Unfortunately this is not a very spectacular example....
// Pushing forward f:
pushForward(f);
// due to pushForward we have got new grading on Q
getVariableWeights();
⇒ 0,0,
⇒ 0,0,
⇒ 0,0,
⇒ 1,0,
⇒ 0,1
getLattice();
⇒ 1,0,0,0,0,
⇒ 0,1,0,0,0,
⇒ 0,0,1,0,0,
⇒ 1,1,1,1,0,
⇒ 1,1,1,1,1
// only for the purpose of this example
if( voice > 1 ){ kill r; }
```

D.15.13.47 gradiator

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\], page 2502](#)).

Purpose: coarsens the grading of the basering until the polynom or ideal `h` becomes homogeneous.

Example:

```
LIB "multigrading.lib";
ring r = 0,(x,y,z),dp;
intmat g[2][3] = 1,0,1,0,1,1;
intmat l[2][1] = 3,0;
setBaseMultigrading(g,l);
getLattice();
↳ 3,0
ideal i = -y5+x4,
y6+xz,
x2y;
gradiator(i);
↳ 1
getLattice();
↳ 3,4,2,
↳ 0,-5,-5
isHomogeneous(i);
↳ 1
```

D.15.13.48 hermiteNormalForm

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\], page 2502](#)).

Usage: `hermiteNormalForm(A);`

Purpose: Computes the (lower triangular) Hermite Normal Form of the matrix `A` by column operations.

Return: `intmat`, the Hermite Normal Form of `A`

Example:

```
LIB "multigrading.lib";
intmat M[2][5] =
1, 2, 3, 4, 0,
0,10,20,30, 1;
// Hermite Normal Form of M:
print(hermiteNormalForm(M));
↳      1      0      0      0      0
↳      0      1      0      0      0
intmat T[3][4] =
3,3,3,3,
2,1,3,0,
1,2,0,3;
// Hermite Normal Form of T:
print(hermiteNormalForm(T));
↳      3      0      0      0
↳      0      1      0      0
↳      3     -1      0      0
intmat A[4][5] =
1,2,3,2,2,
```

```

1,2,3,4,0,
0,5,4,2,1,
3,2,4,0,2;
// Hermite Normal Form of A:
print(hermiteNormalForm(A));
⇒      1      0      0      0      0
⇒      1      2      0      0      0
⇒      0      0      1      0      0
⇒      0      1      0      1      0

```

D.15.13.49 smithNormalForm

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `smithNormalForm(A[,opt]);` intmat A

Purpose: Computes the Smith Normal Form of A

Return: if no optional argument is given: intmat, the Smith Normal Form of A, otherwise: a list of 3 integer matrices P, D Q, such that $D == P \cdot A \cdot Q$.

Example:

```

LIB "multigrading.lib";
intmat A[5][7] =
1,0,1,0,-2,9,-71,
0,-24,248,-32,-96,448,-3496,
0,4,-42,4,-8,30,-260,
0,0,0,18,-90,408,-3168,
0,0,0,-32,224,-1008,7872;
print( smithNormalForm(A) );
⇒      1      0      0      0      0      0      0
⇒      0      2      2      6     12      0      0
⇒      0      0      2      0      0      0      0
⇒      0      0      0      8      0      0      0
⇒      0      0      0      0     48      0      0
list l = smithNormalForm(A, 5);
l;

D.15.13.50 hilbertSeries

Procedure from library `multigrading.lib` (see [Section D.15.13 \[multigrading.lib\]](#), page 2502).

Usage: `hilbertSeries(I)`; I is poly/vector/ideal/module

Purpose: computes the multigraded Hilbert Series of I

Note: input must have multigraded-homogeneous generators.
Multigrading should be positive.

Returns: a ring in variables $t_{-}(i)$, $s_{-}(i)$, with polynomials
numerator1 and denominator1 and mutually prime numerator2 and denominator2, quo-
tients of which give the series.

Example:

```

LIB "multigrading.lib";
ring r = 0,(x,y,z,w),dp;
intmat g[2][4]=
1,1,1,1,
0,1,3,4;
setBaseMultigrading(g);
module M = ideal(xw-yz, x2z-y3, xz2-y2w, yw2-z3);
intmat V[2][1]=
1,
0;
M = setModuleGrading(M, V);
def h = hilbertSeries(M); setring h;
⇒ -----
⇒ This proc returns a ring with polynomials called 'numerator1/2' and 'deno\
  minator1/2'!
⇒ They represent the first and the second Hilbert Series.
⇒ The s_{-}(i)-variables are defined to be the inverse of the t_{-}(i)-variables.
⇒ -----
factorize(numerator2);
⇒ [1]:
⇒ _[1]=-1
⇒ _[2]=t_{-}(1)
⇒ _[3]=t_{-}(1)^3*t_{-}(2)^6-t_{-}(1)^2*t_{-}(2)^6-t_{-}(1)^2*t_{-}(2)^2-t_{-}(1)*t_{-}(2)^3-t_{-}(
  1)*t_{-}(2)-1
⇒ [2]:
⇒ 1,1,1

```

D.15.14 pfd_lib

Library: pfd.lib

Purpose: Multivariate Partial Fraction Decomposition

Author: Marcel Wittmann, e-mail: mwittman@mathematik.uni-kl.de

Overview: This Library implements an algorithm based on the work of E. K. Leinartas to write rational functions in multiple variables as a sum of functions with "smaller" numerators and denominators.

This can be used to shorten the IBP reduction coefficients of multi-loop Feynman integrals. For this application, we also provide a procedure that applies the algorithm to all entries of a matrix of rational functions given as one (possibly very big) txt-file. If you use the library pfd.lib, please cite the corresponding paper [J. Boehm, M. Wittmann, Z. Wu, Y. Xu, Y. Zhang: 'IBP reduction coefficients made simple' (preprint 2020)].

Procedures:

D.15.14.1 pfd

Procedure from library `pfd.lib` (see [Section D.15.14 \[pfd.lib\]](#), page 2560).

Usage: `pfd(f,g[,debug]);` f,g poly, debug int
`pfd(f,g[,debug]);` f poly, g list, debug int
`pfd(arguments[, parallelize]);` arguments list, parallelize int

Return: a partial fraction decomposition of f/g as a list `l` where `l[1]` is an ideal generated by irreducible polynomials and `l[2]` is a list of fractions. Each fraction is represented by a list of

- 1) the numerator polynomial
- 2) an intvec of indices `i` for which `l[1][i]` occurs as a factor in the denominator
- 3) an intvec containing the exponents of those irreducible factors.

Setting `debug` to a positive integer measures runtimes and creates a log file (default: `debug=0`).

The denominator `g` can also be given in factorized form as a list of an ideal of irreducible non constant polynomials and an intvec of exponents. This can save time since the first step in the algorithm is to factorize `g`. (A list of the zero-ideal and an empty intvec represents a denominator of 1.)

If instead of `f` and `g`, the input is a single list (or even a list of lists) containing elements of the form `list(f,g[,debug])` (`f,g,debug` as above), the algorithm is applied to all entries in parallel (using [Section D.2.7 \[parallel.lib\]](#), page 885), if `parallelize=1` (default) and in sequence if `parallelize=0`. A list (or list of lists) of the results is returned.

Note: The result depends on the monomial ordering. For "small" results use `dp`.

Example:

```
LIB "pfd.lib";
ring R = 0,(x,y),dp;
poly f = x^3+3*x^2*y+2*y^2-x^2+4*x*y;
poly g = x^2*y*(x-1)*(x-y)^2;
list dec = pfd(f,g);
⇨ (2) / (q3*q4)
⇨ + (-2) / (q1*q4)
⇨ + (-6) / (q3*q4^2)
```

```

⇒ + (1) / (q2*q4^2)
⇒ + (9) / (q1*q4^2)
⇒ + (2) / (q3^2*q4)
⇒ where
⇒ q1 = x-1

D.15.14.2 checkpfd

Procedure from library `pfd.lib` (see [Section D.15.14 \[pfd.lib\]](#), page 2560).

Usage: `checkpfd(list(f,g),dec[,N,C]);` `f,g` poly, `dec` list, `N,C` int

Return: 0 or 1

Purpose: test for (mathematical) equality of f/g and a partial fraction decomposition `dec`. The list `dec` has to have the same structure as the output of [Section D.15.14.1 \[pfd\]](#), page 2561.

The denominator `g` can also be given in factorized form as a list of an ideal of irreducible non constant polynomials and an intvec of exponents. This can save time since the first step in the algorithm is to factorize `g`. (a list of the zero-ideal and an empty intvec represents a denominator of 1.)

By default the test is done (exactly) by bringing all terms of the decomposition on the same denominator and comparing to f/g .

If additional parameters `N` [, `C`] are given and if $N > 0$, a probabilistic method is chosen: evaluation at `N` random points with coordinates between $-C$ and C . This may be faster for big polynomials.

Example:

```

LIB "pfd.lib";
ring R = 0,(x,y),dp;
poly f = x^3+3*x^2*y+2*y^2-x^2+4*x*y;
poly g = x^2*y*(x-1)*(x-y)^2;
// partial fraction decomposition of f/g:
list dec = pfd(f,g);
⇒ (2) / (q3*q4)
⇒ + (-2) / (q1*q4)
⇒ + (-6) / (q3*q4^2)
⇒ + (1) / (q2*q4^2)
⇒ + (9) / (q1*q4^2)
⇒ + (2) / (q3^2*q4)
⇒ where
⇒ q1 = x-1

```

```

⇒ q2 = y
⇒ q3 = x
⇒ q4 = x-y
⇒ (6 terms)
⇒
// some other decomposition (not equal to f/g):
list wrong_dec = pfd(f+1,g);
⇒ (1) / (q3*q4)
⇒ + (-1) / (q1*q4)
⇒ + (-1) / (q2*q3)
⇒ + (1) / (q1*q2)
⇒ + (-7) / (q3*q4^2)
⇒ + (1) / (q2*q4^2)
⇒ + (10) / (q1*q4^2)
⇒ + (1) / (q3^2*q4)
⇒ + (-1) / (q2*q3^2)
⇒ + (1) / (q3*q4^3)
⇒ + (-1) / (q2*q4^3)
⇒ + (1) / (q3*q4^4)
⇒ + (-1) / (q2*q4^4)
⇒ + (1) / (q3^2*q4^3)
⇒ where
⇒ q1 = x-1
⇒ q2 = y
⇒ q3 = x
⇒ q4 = x-y
⇒ (14 terms)
⇒
displaypfd_long(dec);
⇒ (2)/((x)*(x-y))
⇒ + (-2)/((x-1)*(x-y))
⇒ + (-6)/((x)*(x-y)^2)
⇒ + (1)/((y)*(x-y)^2)
⇒ + (9)/((x-1)*(x-y)^2)
⇒ + (2)/((x)^2*(x-y))
⇒ (6 terms)
⇒
list fraction = f,g;
// exact test:
checkpfd(fraction,dec);
⇒ 1
checkpfd(fraction,wrong_dec);
⇒ 0
// probabilistic test (evaluation at 10 random points):
checkpfd(fraction,dec,10);
⇒ 1
checkpfd(fraction,wrong_dec,10);
⇒ 0

```

See also: [Section D.15.14.1 \[pfd\]](#), page 2561.

D.15.14.3 evaluatepfd

Procedure from library `pfd.lib` (see [Section D.15.14 \[pfd_lib\]](#), page 2560).

Usage: `evaluatepfd(dec, values[, mode]);` dec list, values ideal, mode int

Return: the number gotten by substituting the numbers generating the ideal `values` for the variables in the partial fraction decomposition `dec`. The list `dec` has to have the same structure as the output of [Section D.15.14.1 \[pfd\]](#), page 2561.
`mode=1`: raise Error in case of division by 0 (default)
`mode=2`: return a second integer which is 1 if the denominator becomes 0, and 0 otherwise.

Example:

```
LIB "pfd.lib";
ring R = 0,(x,y),dp;
poly f = x+2*y;
poly g = x^2-y^2;
// partial fraction decomposition of f/g:
list dec = pfd(f,g);
⇒ (-1/2) / (q2)
⇒ + (3/2) / (q1)
⇒ where
⇒ q1 = x-y
⇒ q2 = x+y
⇒ (2 terms)
⇒
displaypfd_long(dec);
⇒ (-1/2)/((x+y))
⇒ + (3/2)/((x-y))
⇒ (2 terms)
⇒
// evaluation at x=2, y=1:
ideal values = 2,1;
evaluatepfd(dec,values);
⇒ 4/3
// compare: f(2,1)/g(2,1) = (2+2*1)/(2^2-1^1) = 4/3
```

See also: [Section D.15.14.1 \[pfd\]](#), page 2561.

D.15.14.4 displaypfd

Procedure from library `pfd.lib` (see [Section D.15.14 \[pfd.lib\]](#), page 2560).

Usage: `displaypfd(dec);` dec list

Purpose: print a partial fraction decomposition `dec` in a readable way. The list `dec` has to have the same structure as the output of [Section D.15.14.1 \[pfd\]](#), page 2561.

Example:

```
LIB "pfd.lib";
ring R = 0,(x,y),dp;
poly f = x^3+3*x^2*y+2*y^2-x^2+4*x*y;
poly g = x^2*y*(x-1)*(x-y)^2;
list dec = pfd(f,g);
⇒ (2) / (q3*q4)
⇒ + (-2) / (q1*q4)
⇒ + (-6) / (q3*q4^2)
⇒ + (1) / (q2*q4^2)
```

```

⇒ + (9) / (q1*q4^2)
⇒ + (2) / (q3^2*q4)
⇒ where
⇒ q1 = x-1
⇒ q2 = y
⇒ q3 = x
⇒ q4 = x-y
⇒ (6 terms)
⇒
displaypfd(dec);
⇒ (2) / (q3*q4)
⇒ + (-2) / (q1*q4)
⇒ + (-6) / (q3*q4^2)
⇒ + (1) / (q2*q4^2)
⇒ + (9) / (q1*q4^2)
⇒ + (2) / (q3^2*q4)
⇒ where
⇒ q1 = x-1
⇒ q2 = y
⇒ q3 = x
⇒ q4 = x-y
⇒ (6 terms)
⇒

```

See also: [Section D.15.14.5 \[displaypfd_long\], page 2568](#); [Section D.15.14.6 \[getStringpfd\], page 2569](#); [Section D.15.14.7 \[getStringpfd_indexed\], page 2570](#); [Section D.15.14.1 \[pfd\], page 2561](#).

D.15.14.5 displaypfd_long

Procedure from library `pfd.lib` (see [Section D.15.14 \[pfd.lib\], page 2560](#)).

Usage: `displaypfd_long(dec); dec list`

Purpose: like [Section D.15.14.4 \[displaypfd\], page 2567](#), but denominators are written out, not indexed.

Example:

```

LIB "pfd.lib";
ring R = 0,(x,y),dp;
poly f = x^3+3*x^2*y+2*y^2-x^2+4*x*y;
poly g = x^2*y*(x-1)*(x-y)^2;
list dec = pfd(f,g);
⇒ (2) / (q3*q4)
⇒ + (-2) / (q1*q4)
⇒ + (-6) / (q3*q4^2)
⇒ + (1) / (q2*q4^2)
⇒ + (9) / (q1*q4^2)
⇒ + (2) / (q3^2*q4)
⇒ where
⇒ q1 = x-1
⇒ q2 = y
⇒ q3 = x
⇒ q4 = x-y
⇒ (6 terms)
⇒

```

```

displaypfd_long(dec);
 $\mapsto (2)/((x)*(x-y))$ 
 $\mapsto + (-2)/((x-1)*(x-y))$ 
 $\mapsto + (-6)/((x)*(x-y)^2)$ 
 $\mapsto + (1)/((y)*(x-y)^2)$ 
 $\mapsto + (9)/((x-1)*(x-y)^2)$ 
 $\mapsto + (2)/((x)^2*(x-y))$ 
 $\mapsto (6 \text{ terms})$ 
 $\mapsto$ 

```

See also: [Section D.15.14.4 \[displaypfd\]](#), page 2567; [Section D.15.14.6 \[getStringpfd\]](#), page 2569; [Section D.15.14.7 \[getStringpfd_indexed\]](#), page 2570; [Section D.15.14.1 \[pfd\]](#), page 2561.

D.15.14.6 getStringpfd

Procedure from library `pfd.lib` (see [Section D.15.14 \[pfd.lib\]](#), page 2560).

Usage: `getStringpfd(dec);` dec list

Purpose: turn a partial fraction decomposition `dec` into one string. The list `dec` has to have the same structure as the output of [Section D.15.14.1 \[pfd\]](#), page 2561.

Example:

```

LIB "pfd.lib";
ring R = 0,(x,y),dp;
poly f = x^3+3*x^2*y+2*y^2-x^2+4*x*y;
poly g = x^2*y*(x-1)*(x-y)^2;
list dec = pfd(f,g);
 $\mapsto (2) / (q3*q4)$ 
 $\mapsto + (-2) / (q1*q4)$ 
 $\mapsto + (-6) / (q3*q4^2)$ 
 $\mapsto + (1) / (q2*q4^2)$ 
 $\mapsto + (9) / (q1*q4^2)$ 
 $\mapsto + (2) / (q3^2*q4)$ 
 $\mapsto$  where
 $\mapsto q1 = x-1$ 
 $\mapsto q2 = y$ 
 $\mapsto q3 = x$ 
 $\mapsto q4 = x-y$ 
 $\mapsto (6 \text{ terms})$ 
 $\mapsto$ 
displaypfd_long(dec);
 $\mapsto (2)/((x)*(x-y))$ 
 $\mapsto + (-2)/((x-1)*(x-y))$ 
 $\mapsto + (-6)/((x)*(x-y)^2)$ 
 $\mapsto + (1)/((y)*(x-y)^2)$ 
 $\mapsto + (9)/((x-1)*(x-y)^2)$ 
 $\mapsto + (2)/((x)^2*(x-y))$ 
 $\mapsto (6 \text{ terms})$ 
 $\mapsto$ 
getStringpfd(dec);
 $\mapsto (2)/((x)*(x-y)) + (-2)/((x-1)*(x-y)) + (-6)/((x)*(x-y)^2) + (1)/((y)*(x-y)^2) + (9)/((x-1)*(x-y)^2) + (2)/((x)^2*(x-y))$ 

```

See also: [Section D.15.14.4 \[displaypfd\]](#), page 2567; [Section D.15.14.5 \[displaypfd_long\]](#), page 2568; [Section D.15.14.7 \[getStringpfd_indexed\]](#), page 2570; [Section D.15.14.1 \[pfd\]](#), page 2561.

D.15.14.7 getStringpfd_indexed

Procedure from library `pfd.lib` (see [Section D.15.14 \[pfd.lib\]](#), page 2560).

Usage: `getStringpfd_indexed(dec);` dec list

Purpose: turn a partial fraction decomposition `dec` into one string, writing the denominator factors just as `q1,q2,...`. The list `dec` has to have the same structure as the output of [Section D.15.14.1 \[pfd\]](#), page 2561.

Example:

```
LIB "pfd.lib";
ring R = 0,(x,y),dp;
poly f = x^3+3*x^2*y+2*y^2-x^2+4*x*y;
poly g = x^2*y*(x-1)*(x-y)^2;
list dec = pfd(f,g);
  => (2) / (q3*q4)
  => + (-2) / (q1*q4)
  => + (-6) / (q3*q4^2)
  => + (1) / (q2*q4^2)
  => + (9) / (q1*q4^2)
  => + (2) / (q3^2*q4)
  => where
  => q1 = x-1
  => q2 = y
  => q3 = x
  => q4 = x-y
  => (6 terms)
  =>
displaypfd(dec);
  => (2) / (q3*q4)
  => + (-2) / (q1*q4)
  => + (-6) / (q3*q4^2)
  => + (1) / (q2*q4^2)
  => + (9) / (q1*q4^2)
  => + (2) / (q3^2*q4)
  => where
  => q1 = x-1
  => q2 = y
  => q3 = x
  => q4 = x-y
  => (6 terms)
  =>
getStringpfd_indexed(dec);
  => (2)/(q3*q4) + (-2)/(q1*q4) + (-6)/(q3*q4^2) + (1)/(q2*q4^2) + (9)/(q1*q4^2) + (2)/(q3^2*q4)
```

See also: [Section D.15.14.4 \[displaypfd\]](#), page 2567; [Section D.15.14.5 \[displaypfd_long\]](#), page 2568; [Section D.15.14.6 \[getStringpfd\]](#), page 2569; [Section D.15.14.1 \[pfd\]](#), page 2561.

D.15.14.8 readInputTXT

Procedure from library `pfd.lib` (see [Section D.15.14 \[pfd.lib\]](#), page 2560).

Usage: `readInputTXT(file[, mode]);` file string, mode int
`readInputTXT(filelist[, mode]);` filelist list, mode int

Purpose: read matrix of rational functions from a txt-file and turn it into a matrix (i.e. a list of lists) of pairs of polynomials (numerators and denominators). The string `file` should be the [directory +] name of the file in the form "`<path-to-file>/<filename>.txt`". The input file should be a list of lists separated by the characters "{", "}" and ",". Example:
`"{{(x+y)/(x^2-x*y), -(x^2*y+1)/(y), x^2}, {(x+1)/y, y/x, 0}}"`
 Each rational function has to be an expression of the form "`a`", "`a/(b)`", "`(b)^(-n)`" or "`(a)*(b)^(-n)`" where "`a`", "`b`" stand for polynomials (i.e. strings, that can be parsed as a polynomial with the `execute` command) and "`n`" stands for a positive integer. A minus sign "-" followed by such an expression is also allowed.
IMPORTANT: The strings "`a`", "`b`" must NOT contain the symbol "/". (So in case the coefficient field is the rationals, all denominators in the coefficients of numerator and denominator polynomials should be cleared.)
 The file should contain less than 2^{31} characters (filesize < 2 GB). For bigger files the matrix should be split row-wise into multiple matrices and saved in different files (each smaller than 2 GB). A list of the filenames (in the right order) can then be given as first argument instead.
 Also the basering has to match the variable names used in the input file(s).
`mode=1` (default): save result to an ssi-file of the same name
`mode=2`: return result
`mode=3`: save to ssi-file AND return result

See also: [Section D.15.14.9 \[pfdMat\]](#), page 2571.

D.15.14.9 pfdMat

Procedure from library `pfd.lib` (see [Section D.15.14 \[pfd.lib\]](#), page 2560).

Usage: `pfdMat(file[, dotest, ignore_nonlin, output_mode, parallelize]);` file string, dotest, ignore_nonlin, output_mode, parallelize int

Purpose: apply `pfd` to all entries of a matrix of rational functions saved in a txt-file. The string `file` should be the [directory +] name of the file.
 The input file can either be a txt-file or an ssi-file created with `readInputTXT`. In case of a txt-file, the base ring has to match and the matrix has to be in the same format specified in [Section D.15.14.8 \[readInputTXT\]](#), page 2570. Also, txt-files that are bigger than 2 GB should be split as described for `readInputTXT` and a list of the filenames can be given as first argument instead.
 The result is saved in multiple txt- (and ssi-) files (see below) within the directory of the input file.
 Also a logfile is created, which protocols the memory used and the runtimes of `pfd` for each matrix entry in real-time.

There are also 4 optional arguments:

If `dotest` is nonzero, test the results with `checkpfd`:

`dotest<0` (default): exact test (may be slow),

`dotest>0`: do this amount of probabilistic tests for each entry (see [Section D.15.14.2 \[checkpfd\]](#), page 2565).

If `ignore_nonlin` is nonzero (default), for each denominator, the nonlinear factors in the factorization are removed before applying `pfd` (and added back in in the output files).

If `parallelize` is nonzero (default), the decompositions are calculated in parallel using [Section D.2.7 \[parallel_lib\]](#), page 885.

The parameter `output_mode` controls the output files created:

`output_mode=1` (default): The result consists of two files: `<filename>_pfd_indexed.txt` contains the matrix of all decompositions (as list of lists separated by the characters "{", "}" and ",") where all the denominators are written in factorized form depending on irreducible factors `q1`, `q2`, The file `<filename>_denominator_factors.txt` lists all the polynomials `q1`, `q2`,

`output_mode=2`: Additionally to mode 1, the file `<filename>_pfd.txt` is created, which also contains the matrix of decompositions but the factors in the denominators are written out.

`output_mode=3`: Additionally to mode 2, the result and some intermediate results are saved as SINGULAR objects in ssi-files:

`<filename>.ssi`: contains the result of `readInputTXT` in case a txt-file was given as input.

`<filename>_factorized_denominators.ssi`: like the first file, but the denominators are saved in factorized form, that is as a list of an ideal of irreducible non constant polynomials and an intvec of exponents.

`<filename>_linear_part.ssi` (only if `ignore_nonlin` is nonzero): like the previous file, but all the irreducible denominator factors are removed

`<filename>_non_linear_factors.ssi` (only if `ignore_nonlin` is nonzero): a list of an ideal `p` generated by irreducible polynomials and a matrix (list of lists) of the nonlinear denominator factors of each entry of the input matrix. These are represented as lists of an intvec of indices `i` for which `p[i]` occurs as a (nonlinear) factor in the denominator and an intvec containing the exponents of those factors.

`<filename>_pfd.ssi`: a list, where the first entry is an ideal `q` of denominator factors and the second entry is a matrix (as list of lists) containing the decompositions, each of which is a list of terms, where a term is represented as in the result of [Section D.15.14.1 \[pfd\]](#), page 2561 by a list containing

- 1) the numerator polynomial
- 2) an intvec of indices `i` for which `q[i]` occurs as a factor in the denominator
- 3) an intvec containing the exponents of those irreducible factors.

IMPORTANT: If `ignore_nonlin` is nonzero, this file contains the decompositions of the entries of the matrix in `<filename>_linear_part.ssi`. Thus the nonlinear factors, are NOT contained in this file.

`output_mode=4`: Additionally to mode 3, the direct output of each call of `pfd` is saved in separate ssi-files called `pfd_results_i_j.ssi` where `i,j` are the matrix indices. This creates a lot of files, but may be useful in case the algorithm does not terminate in time for every matrix entry. Other than the files created in mode 1-3, these files are saved in the current directory, rather than the directory of the input file.

See also: [Section D.15.14.2 \[checkpfd\]](#), page 2565; [Section D.15.14.10 \[checkpfdMat\]](#), page 2572; [Section D.15.14.1 \[pfd\]](#), page 2561; [Section D.15.14.8 \[readInputTXT\]](#), page 2570.

D.15.14.10 checkpfdMat

Procedure from library `pfd.lib` (see [Section D.15.14 \[pfd_lib\]](#), page 2560).

Usage: `checkpfdMat(input, output, denomFactors[, N, parallelize]);` `input,output,denomFactors` string, `N,parallelize` int

Purpose: test the output files of `pfdMat` for correctness. Input and output (indexed) txt-files have to be given as strings in the form "`<path-to-file>/<filename>.txt`". The output should be indexed (that is the output file ending in `..._pfd_indexed.txt`) and `denomFactors` has to be the file containing the denominator factors `q1`, `q2`, ... (the txt-file ending in `..._denominator_factors.txt`).
 As for `readInputTXT` and `pfdMat`, the basering has to match the variable names used in the input file, which has to be in the same format specified in [Section D.15.14.8 \[readInputTXT\]](#), page 2570. Also, files bigger than 2 GB have to be split as described for `readInputTXT` and a list of filenames can be given as first argument instead.
 If a positive integer `N` is given, the test is done probabilistically by evaluation at `N` random points for each entry of the matrix. If `N` is nonpositive (default), the fractions in the decompositions will be expanded symbolically and compared to the input (may be slower).
 If `parallelize` is nonzero (default), the tests are run in parallel using [Section D.2.7 \[parallel_lib\]](#), page 885.
 The result is printed and as in `pfdMat` a logfile is created showing the results for each matrix entry.

See also: [Section D.15.14.2 \[checkpfd\]](#), page 2565; [Section D.15.14.1 \[pfd\]](#), page 2561; [Section D.15.14.9 \[pfdMat\]](#), page 2571; [Section D.15.14.8 \[readInputTXT\]](#), page 2570.

D.15.15 polyclass_lib

Library: `polyclass.lib`

Purpose: Data types for normal form equations

Authors: Janko Boehm, email: boehm@mathematik.uni-kl.de
 Magdaleen Marais, email: magdaleen.marais@up.ac.za
 Gerhard Pfister, email: pfister@mathematik.uni-kl.de

Overview: This library implements a ring independent polynomial type used for the return value in `classify2.lib`, `realclassify.lib` and `arnold.lib`. You can use `+`, `*` and `==` for addition, multiplication and comparison. The key over contains the base ring of the polynomial, the key value its value as a polynomial of type `poly`. The constructor can be called by assigning a polynomial of type `poly` to a polynomial of type `Poly` via `=`.

Moreover the library implements a ring independent class `Normalform` consisting out of fields of type `string`, type `list`, type `Poly` and type `RightEquivalenceChainWithPrecision`, that capture the important characteristics of the stored singularity. The type `RightEquivalenceChainWithPrecision` is created to store a chain of (finite) transformations, ring independently as a list, performed on a sourcegerm. The image of the sourcegerm is stored in the field `targetgerm`. In this way the chain of transformations used to transform a sourcegerm to a normalformequation can be documented. To store each individual transformation the library implements a ring independent transformation of type `PolynomialRightEquivalence`, which contains fields for the ring over which the transformation is performed, the images that defines the transformation as a list of `Poly`'s, and the inverse images that defined the inverse transformation as a list of `Poly`'s.

The library also contains print functions for the newly created types for a user friendly display.

Procedures: See also: [Section D.15.1 \[arnold_lib\]](#), page 2277; [Section D.6.5 \[classify2_lib\]](#), page 1659; [Section D.6.19 \[realclassify_lib\]](#), page 1750.

D.15.15.1 makePoly

Procedure from library `polyclass.lib` (see [Section D.15.15 \[polyclass_lib\]](#), page 2573).

Usage: `makePoly(f); f poly`

Return: make a ring independent Poly from a poly in the basering

Example:

```
LIB "polyclass.lib";
ring R=0,(x,y),dp;
poly f=3*x^2+x*y+1;
Poly F = makePoly(f);
F.in;
⇒ // coefficients: QQ
⇒ // number of vars : 2
⇒ //      block   1 : ordering dp
⇒ //                : names    x y
⇒ //      block   2 : ordering C
F.value;
⇒ 3x2+xy+1
```

D.15.15.2 printPoly

Procedure from library `polyclass.lib` (see [Section D.15.15 \[polyclass_lib\]](#), page 2573).

D.15.15.3 addPoly

Procedure from library `polyclass.lib` (see [Section D.15.15 \[polyclass_lib\]](#), page 2573).

D.15.15.4 multPoly

Procedure from library `polyclass.lib` (see [Section D.15.15 \[polyclass_lib\]](#), page 2573).

D.15.15.5 equalPoly

Procedure from library `polyclass.lib` (see [Section D.15.15 \[polyclass_lib\]](#), page 2573).

D.15.15.6 expPoly

Procedure from library `polyclass.lib` (see [Section D.15.15 \[polyclass_lib\]](#), page 2573).

D.15.15.7 printPolynomialRightEquivalence

Procedure from library `polyclass.lib` (see [Section D.15.15 \[polyclass.lib\]](#), page 2573).

Usage: `printPolynomialRightEquivalence(RE);` RE PolynomialRightEquivalence

Return: print the transformation RE

Example:

```
LIB "polyclass.lib";
ring R=0,(x,y),dp;
PolynomialRightEquivalence RE;
RE.in=basing;
RE.images = list(makePoly(x-x*y),makePoly(y));
RE.imagesInverse = list(makePoly(x+x*y),makePoly(y));
printPolynomialRightEquivalence(RE);
↪
↪ Transformation:
↪ x-->-xy+x
↪ y-->y
```

D.15.15.8 printRightEquivalenceChainWithPrecision

Procedure from library `polyclass.lib` (see [Section D.15.15 \[polyclass.lib\]](#), page 2573).

Usage: `printRightEquivalenceChainWithPrecision(TT);` TT RightEquivalenceChainWithPrecision

Return: print the chain of transformations TT

Example:

```
LIB "polyclass.lib";
RightEquivalenceChainWithPrecision TT;
ring R=0,(x,y),ds;
poly f = x+y;
Poly F = makePoly(f);
TT.sourcegerm = F;
map phi = R,x-x*y,y;
f=phi(f);
PolynomialRightEquivalence RE;
RE.in=basing;
RE.images = list(makePoly(x-x*y),makePoly(y));
RE.imagesInverse = list(makePoly(x+x*y),makePoly(y));
TT.transformations[size(TT.transformations)+1]=RE;
TT.targetgerm.in = basering;

D.15.15.9 printNormalFormEquation

Procedure from library `polyclass.lib` (see [Section D.15.15 \[polyclass.lib\]](#), page 2573).

Usage: `printNormalFormEquation(F)`; F NormalFormEquation

Return: print a normal form equation

Example:

```

LIB "polyclass.lib";
ring R=(0,a),(x,y,z,w),ds;
minpoly = a^2-2;
Poly f=x^4+x^2*y^2+a*y^8+z^2-w^2;
NormalFormEquation F;
F.vars = ringlist(R)[2];
F.realCase = 1;
F.normalFormEquation = f;
F.modality = 1;
F.corank = 2;
F.inertiaIndex = 1;
F.determinacy = 8;
F.milnorNumber = milnor(f.value);
F.parameters = list(list(a*y^8,list(0,2)));
F.singularityType = "X[13]";
F;
↳ Corank = 2
↳ Inertia index = 1
↳ Normalform equation of type = X[13]
↳ Normalform equation = z2-w2+x4+x2y2+(a)*y8
↳ Milnor number = 13
↳ Modality = 1

```

```

⇒ Parameter term = (a)*y8
⇒ Minimal polynomial = (a2-2)
⇒ Interval = [0, 2]
⇒ Determinacy <= 8
⇒
ring R=(0),(x,y,z,w),ds;
⇒ // ** redefining R (ring R=(0),(x,y,z,w),ds;) ./examples/printNormalFormE\

⇒ Determinacy <= 8

```

D.15.15.10 printNormalForm

Procedure from library `polyclass.lib` (see [Section D.15.15 \[polyclass.lib\]](#), page 2573).

Usage: `printNormalForm(F);` F NormalForm

Return: print a normalform with its important characteristics

Example:

```

LIB "polyclass.lib";
ring R=(0,a),(x,y),ds;
minpoly = a^2-2;
poly f=x^4+x^2*y^2+7*a*y^8;
Poly F = makePoly(f);

D.15.16 puiseuxexpansions_lib

Library: puiseuxexpansion.lib

Purpose: Puiseux expansions over algebraic extensions

Authors: J. Boehm, j.boehm at mx.uni-saarland.de
 W. Decker, decker at mathematik.uni-kl.de
 S. Laplagne, slaplagn at dm.uba.ar
 G. Pfister, seelisch at mathematik.uni-kl.de

Overview: This library implements the Newton-Puiseux algorithm to compute Puiseux expansions and provides a class and procedures to work with Puiseux expansions in $K[X][Y]$, where K is the field \mathbb{Q} of rational numbers or an algebraic extension of \mathbb{Q} .

Procedures:

D.15.16.1 puiseuxList

Procedure from library `puiseuxexpansions.lib` (see [Section D.15.16 \[puiseuxexpansions_lib\]](#), [page 2578](#)).

Usage: `puiseuxList(PP, maxDeg, iVarX, iVarY)`; Puiseux expansion PP, int maxDeg is the integer up to which the Puiseux expansions will be computed (if maxDeg = -1 computes the singular part),
int iVarX is the index of the X variable for the ring $C\{X\}[Y]$, int iVarY, the index of the Y variable for the ring $C\{X\}[Y]$.

Assume: basering has exactly two variables;
f is convenient, that is, $f(x,0) \neq 0 \neq f(0,y)$.

Return: a list with the Puiseux expansions of PP.

Example:

```
LIB "puiseuxexpansions.lib";
ring r=0,(x,y),dp;
Puisseux PP = x5+2x3y-x2y2+3xy5+y6+y7;
puiseuxList(PP, 5, 1, 2);
⇒ [1]:
⇒ ( 6326x5+634x4+71x3+10x2+3x-1 ) / 1

```

D.15.16.2 makePuisseux

Procedure from library `puiseuxexpansions.lib` (see [Section D.15.16 \[puiseuxexpansions.lib\]](#), [page 2578](#)).

Usage: `makePuisseux(f, denom, fr)`; f polynomial in two variables, denom polynomial in the first variable of the ring, int fr

Return: make a ring independent polynomial over Puiseux series

Example:

```

LIB "puiseuxexpansions.lib";
ring R=0,(x,y),dp;
poly f=3*x^2+x*y+1;
makePuisseux(f,x^2,3);
 $\mapsto (3x^2+xy+1) / x^2$ 
 $\mapsto$  Denominator of exponent : 3
 $\mapsto$ 

```

D.15.16.3 makePuisseuxFromPoly

Procedure from library `puiseuxexpansions.lib` (see [Section D.15.16 \[puiseuxexpansions.lib\]](#), [page 2578](#)).

Usage: `makePuisseuxFromPoly(f)`; f polynomial in two variables

Return: make a ring independent polynomial over Puiseux series

Example:

```

LIB "puiseuxexpansions.lib";
ring R=0,(x,y),dp;
poly f=3*x^2+x+1;
makePuisseuxFromPoly(f);
 $\mapsto (3x^2+x+1) / 1$ 
 $\mapsto$  Denominator of exponent : 1
 $\mapsto$ 

```

D.15.16.4 printPuisseux

Procedure from library `puiseuxexpansions.lib` (see [Section D.15.16 \[puiseuxexpansions.lib\]](#), [page 2578](#)).

Usage: `printPuisseux(f)`; f Puiseux expansion

Return: prints information for Puiseux elements

Example:

```

LIB "puiseuxexpansions.lib";
ring R=0,(x,y),dp;
poly f=3*x^2+x*y+1;
Puisseux F = makePuisseux(f,x^2,3);
printPuisseux(F);
 $\mapsto (3x^2+xy+1) / x^2$ 
 $\mapsto$  Denominator of exponent : 3

```

D.15.16.5 puiseux

Procedure from library `puiseuxexpansions.lib` (see [Section D.15.16 \[puiseuxexpansions.lib\]](#), [page 2578](#)).

Usage: `puiseux(f, maxDeg, atOrigin)`; f polynomial in two variables, `int maxDeg`, `int atOrigin`

Return: the Puiseux expansions of f developed up to degree `maxDeg`. If `atOrigin = 1`, only the expansions passing through the origin will be returned.

Example:

```

LIB "puiseuxexpansions.lib";
ring R=0,(x,y),dp;
poly f=y^3 + x^2 + x^8;
puiseux(f,3,0);
⇒ [1]:
⇒      [1]:
⇒      -1/3x20-x2
⇒      [2]:
⇒      3
⇒      [6]:
⇒      [1]:
⇒      1
⇒      [2]:
⇒      1
⇒      [7]:
⇒      [1]:
⇒      2

```

D.15.17 ringgb.lib

Library: ringgb.lib

Purpose: Functions for coefficient rings

Author: Oliver Wienand, email: wienand@mathematik.uni-kl.de

Procedures:

D.15.17.1 findZeroPoly

Procedure from library ringgb.lib (see [Section D.15.17 \[ringgb.lib\]](#), page 2581).

Usage: findZeroPoly(f); f - a polynomial

Return: zero polynomial with the same leading term as f if exists, otherwise 0

Example:

```

LIB "ringgb.lib";
ring r = (integer, 65536), (y,x), dp;
poly f = 1024*x^8*y^2+11264*x^8*y+28672*x^8+45056*x^7*y^2+36864*x^7*y+16384*x^7+40960*x^6*y^2+
440960*yx5+53248y2x3+15360yx4+12288y2x2+12288yx3+16384y2x+53248yx2+49152y\
x

```

D.15.17.2 zeroReduce

Procedure from library ringgb.lib (see [Section D.15.17 \[ringgb.lib\]](#), page 2581).

Usage: zeroReduce(f, [i = 0]); f - a polynomial, i - noise level (if != 0 prints all steps)

Return: reduced normal form of f modulo zero polynomials

Example:

```

LIB "ringgb.lib";
ring r = (integer, 65536), (y,x), dp;
poly f = 1024*x^8*y^2+11264*x^8*y+28672*x^8+45056*x^7*y^2+36864*x^7*y+16384*x^7+40960*x^6*y^2+
440960*yx5+53248y2x3+15360yx4+12288y2x2+12288yx3+16384y2x+53248yx2+49152y\
x

```

```

zeroReduce(f);
↳ 0
kill r;
ring r = (integer, 2, 32), (x,y,z), dp;
// Polynomial 1:
poly p1 = 3795162112*x^3+587202566*x^2*y+2936012853*x*y*z+2281701376*x+548767119*y^3+
// Polynomial 2:
poly p2 = 1647678464*x^3+587202566*x^2*y+2936012853*x*y*z+134217728*x+548767119*y^3+
zeroReduce(p1-p2);
↳ 0

```

D.15.17.3 testZero

Procedure from library `ringgb.lib` (see [Section D.15.17 \[ringgb.lib\]](#), page 2581).

Usage: `testZero(f)`; f - a polynomial

Return: returns 1 if f is zero as a function and otherwise a counterexample as a list $[f(x_1, \dots, x_n), x_1, \dots, x_n]$

Example:

```

LIB "ringgb.lib";
ring r = (integer, 12), (y,x), dp;
poly f = 1024*x^8*y^2+11264*x^8*y+28672*x^8+45056*x^7*y^2+36864*x^7*y+16384*x^7+4096
//zeroReduce(f);
testZero(f);
↳ Teste 144 Belegungen ...
↳ bisher: 11
↳ [1]:
↳ 1
↳ [2]:
↳ 1
↳ [3]:
↳ 4
poly g = findZeroPoly(x2y3);
g;
↳ y3x2+11y3x+9y2x2+3y2x+2yx2+10yx
testZero(g);
↳ Teste 144 Belegungen ...
↳ bisher: 11
↳ bisher: 23
↳ bisher: 35
↳ bisher: 47
↳ bisher: 59

↳ bisher: 83
↳ bisher: 95
↳ bisher: 107
↳ bisher: 119
↳ bisher: 131
↳ bisher: 143
↳ 1

```

D.15.17.4 noElements

Procedure from library `ringgb.lib` (see [Section D.15.17 \[ringgb.lib\]](#), page 2581).

Usage: `noElements(r)`; `r` - a ring with a finite coefficient ring of type integer

Return: returns the number of elements of the coefficient ring of `r`

Example:

```
LIB "ringgb.lib";
ring r = (integer, 233,6), (y,x), dp;
noElements(r);
↦ 160005726539569
```

D.15.18 rwalk.lib

Library: `rwalk.lib`

Purpose: Groebner Walk Conversion Algorithms

Author: Stephan Oberfranz

Procedures: See also: [Section D.4.10 \[grwalk.lib\]](#), page 1089; [Section D.15.24 \[swalk.lib\]](#), page 2601.

D.15.18.1 prwalk

Procedure from library `rwalk.lib` (see [Section D.15.18 \[rwalk.lib\]](#), page 2583).

Syntax: `prwalk(ideal i, int radius)`;
if `size(#)>0` then `prwalk(ideal i, int radius, intvec v, intvec w)`;

Type: ideal

Purpose: compute the standard basis of the ideal, calculated via the Random Perturbation Walk algorithm from the ordering `"(a(v),lp)"`, `"dp"`, `"Dp"` or `"M"` to the ordering `"(a(w),lp)"`, `"(a(1,0,...,0),lp)"` or `"M"`.

Example:

```
LIB "rwalk.lib";
// compute a Groebner basis of I w.r.t. lp.
ring r = 32003,(z,y,x), lp;
ideal I = y3+xyz+y2z+xz3, 3+xy+x2y+y2z;
int radius = 1;
int o_perturb_deg = 2;
int t_perturb_deg = 2;
prwalk(I,radius,o_perturb_deg,t_perturb_deg);
↦ _[1]=y9-y7x2-y7x-y6x3-y6x2-3y6-3y5x-y3x7-3y3x6-3y3x5-y3x4-9y2x5-18y2x4-9y\
2x3-27yx3-27yx2-27x
↦ _[2]=zx+8297y8x2+8297y8x+3556y7-8297y6x4+15409y6x3-8297y6x2-8297y5x5+1540\

D.15.18.2 rwalk

Procedure from library `rwalk.lib` (see [Section D.15.18 \[rwalk.lib\]](#), page 2583).

Syntax: `rwalk(ideal i, int radius);`
`if size(#)>0 then rwalk(ideal i, int radius, intvec v, intvec w);` intermediate Groebner bases are not reduced if `reduction = 0`

Type: ideal

Purpose: compute the standard basis of the ideal, calculated via the Random walk algorithm from the ordering
`"(a(v),lp)", "dp", "Dp" or "M"`
to the ordering `"(a(w),lp)", "(a(1,0,...,0),lp)" or "M"`.

Example:

```
LIB "rwalk.lib";
// compute a Groebner basis of I w.r.t. lp.
ring r = 32003,(z,y,x), lp;
ideal I = y3+xyz+y2z+xz3, 3+xy+x2y+y2z;
int radius = 1;
int perturb_deg = 2;
rwalk(I,radius,perturb_deg);

D.15.18.3 frandwalk

Procedure from library `rwalk.lib` (see [Section D.15.18 \[rwalk.lib\]](#), page 2583).

Syntax: `frwalk(ideal i, int radius);`
`frwalk(ideal i, int radius, intvec v, intvec w);`

Type: ideal

Purpose: compute the standard basis of the ideal w.r.t. the lexicographical ordering or a weighted-lex ordering, calculated via the Random Fractal walk algorithm.

Example:

```
LIB "rwalk.lib";
ring r = 0,(z,y,x), lp;
ideal I = y3+xyz+y2z+xz3, 3+xy+x2y+y2z;
int reduction = 0;
frandwalk(I,2);
↪ _[1]=y9-y7x2-y7x-y6x3-y6x2-3y6-3y5x-y3x7-3y3x6-3y3x5-y3x4-9y2x5-18y2x4-9y\

D.15.19 sagbigrob_lib

Library: sagbigrob.lib

Purpose: Compute Sagbi-Groebner basis of an ideal of a subalgebra

Authors: Nazish Kanwal, Lecturer of Mathematics, School of Mathematics and Computer Science, Institute of Business Administration, Karachi, Pakistan
 Junaid Alam Khan, Associate Professor of Mathematics, School of Mathematics and Computer Science, Institute of Business Administration, Karachi, Pakistan

Procedures: See also: [Section D.4.32 \[sagbi_lib\]](#), page 1380.

D.15.19.1 LTGS

Procedure from library `sagbigrob.lib` (see [Section D.15.19 \[sagbigrob_lib\]](#), page 2585).

Usage: LTGS(I,A); I ideal of subalgebra A, A subalgebra (which is a finite sagbi basis).

Return: a module M.

Example:

```

LIB "sagbigrob.lib";
// Example 1:
ring r=ZZ,(x,y),Dp;
ideal A=2x2+xy,2y2,3xy;
ideal I=4x2y2+2xy3,18x2y4,36xy5;
LTGS(I,A);
⇒ _[1]=9y2*gen(1)-2*gen(2)
⇒ _[2]=9y4*gen(1)-xy*gen(3)
⇒ _[3]=-xy*gen(3)+2y2*gen(2)
⇒ _[4]=xy3*gen(1)
⇒ _[5]=-18xy3*gen(1)+2x2*gen(3)+xy*gen(3)
// Example 2:
ring r2=QQ,(x,y),Dp;
ideal A=x2,xy;
ideal I=x3y+x2,x4+x2y2,-x3y3-x2y2;
LTGS(I,A);
⇒ _[1]=x2*gen(1)-xy*gen(2)
⇒ _[2]=-x2y2*gen(1)-x2*gen(3)
⇒ _[3]=-x3y3*gen(2)-x4*gen(3)

```

D.15.19.2 SGNF

Procedure from library `sagbigrob.lib` (see [Section D.15.19 \[sagbigrob_lib\]](#), page 2585).

Usage: SGNF(f,I,A); f polynomial, I ideal of subalgebra A, A ideal (which is a finite Sagbi bases).

Return: a polynomial h: the normalform of f wrt. I in A

Example:

```
LIB "sagbigrob.lib";
ring r=0,(x,y),Dp;
ideal A=x2,xy;
ideal I=x3y+x2,x4+x2y2,-x3y3-x2y2;
poly f=x6y6+x2;
poly g=x12+x6y6-x8+x5y;
SGNF(f,I,A);
↦ x2y2+x2
SGNF(g,I,A);
↦ 0
```

D.15.19.3 SPOLY

Procedure from library `sagbigrob.lib` (see [Section D.15.19 \[sagbigrob.lib\]](#), page 2585).

Usage: SPOLY(I,A); I ideal of subalgebra A, A subalgebra (which is a finite sagbi basis).

Return: an ideal S: S-polynomials of ideal I

Example:

```
LIB "sagbigrob.lib";
// Example 1:
ring r=ZZ,(x,y),Dp;
ideal A=2x2+xy,2y2,3xy;
ideal I=4x2y2+2xy3,18x2y4;
SPOLY(I,A);
↦ _[1]=18xy5
↦ _[2]=4x3y5+2x2y6
// Example 2:
ring r2=QQ,(x,y),Dp;
ideal A=x2,xy;
ideal I=x3y+x2,x4+x2y2,-x3y3-x2y2;
SPOLY(I,A);
↦ _[1]=-x3y3+x4
↦ _[2]=-x5y5+x6y2
```

D.15.19.4 SGB

Procedure from library `sagbigrob.lib` (see [Section D.15.19 \[sagbigrob.lib\]](#), page 2585).

Usage: SGB(I,A); I ideal of subalgebra A, A subalgebra (which is a finite sagbi basis).

Return: an ideal SB.

Example:

```
LIB "sagbigrob.lib";
// Example 1:
ring r=ZZ,(x,y),Dp;
ideal A=2x2+xy,2y2,3xy;
ideal I=4x2y2+2xy3,18x2y4;
```

```

SGB(I,A);
↦ 18xy5
↦ 0
↦ 0
↦ -2x2y6+8xy7
↦ 0
↦ 0
↦ 0
↦ _[1]=4x2y2+2xy3
↦ _[2]=18x2y4
↦ _[3]=18xy5
↦ _[4]=-2x2y6+8xy7
// Example 2:
ring r2=QQ,(w,x,y,z),lp;
ideal A=wxy+2z2, y2-4z, x+3y;
ideal I= wxy-y2+2z2+4z, x+y2+3y-4z, x2+6xy+9y2;
SGB(I,A);
↦ 0
↦ -y6+12y4z-48y2z2+64z3
↦ 0
↦ _[1]=wxy-y2+2z2+4z
↦ _[2]=x+y2+3y-4z
↦ _[3]=x2+6xy+9y2
↦ _[4]=-y6+12y4z-48y2z2+64z3

```

D.15.20 sagbiNormaliz_lib

Library: sagbiNormaliz.lib

Purpose: Provides an interface for the computation of Sagbi bases. It uses normaliz.lib (version 4... or higher) for combinatorial computations.

Authors: Winfried Bruns, wbruns@uos.de

Overview: The library sagbiNormaliz.lib provides functions for the computations of Sagbi bases. It is based on normaliz.lib. Its functions compute Sagbi bases with or without the control by Hilbert functions and/orv degrees. Hilbert functions and degrees require that the ambient polynomial ring is standard graded. (An extension to general positive gradings would not be difficult.)

Use of this library requires the program Normaliz to be installed and the availability of normaliz.lib. You can download both from [@uref{https://github.com/Normaliz/Normaliz/releases}](https://github.com/Normaliz/Normaliz/releases). Please make sure that the executable is in the search path or use setNmzExecPath (defined in normaliz.lib).

The computations of this library require reading Normaliz output files and therefore a file name must be set. The standard file name chosen by the library is NmzSagbiExchange in the current directory. The user can overwrite it by setting another name.

Procedures:

D.15.20.1 sagbiGeneral

Procedure from library sagbiNormaliz.lib (see [Section D.15.20 \[sagbiNormaliz_lib\]](#), page 2587).

Usage: `sagbiGeneral(ideal Q [, int sagbiMaxRounds, int sorting, int verb]);`

Return: An ideal whose generators form the Sagbi basis of the algebra generated by the polynomials in Q as far as computed in at most `sagbiMaxRounds`.
 If sorting is set, the computed elements are degrevlex sorted before a round of the algorithm. The optional parameter `verb` sets the terminal output. Default is 1 = on.
 The component has a second integer component. Its possible values are: 0, if the full Sagbi basis has not been reached, 1 if this is unknown, and 2 if the full Sagbi basis has been computed.

Example:

```
LIB "sagbiNormaliz.lib";
ring R = 0, (x,y,z),dp;
ideal P = x^6+y^6+z^6, x^7+y^7+z^7;
ideal Q;
int success;
// at most 3 rounds, no sorting, no terminal output
(Q,success) = sagbiGeneral(P,3,0,0);
Q;
⇒ Q[1]=x6+y6+z6
⇒ Q[2]=x7+y7+z7
⇒ Q[3]=x36y6-6/7x35y7+3x30y12-15/7x28y14+5x24y18-20/7x21y21+5x18y24-15/7x14\
y28+3x12y30-6/7x7y35+x6y36+x36z6+6x30y6z6+15x24y12z6+20x18y18z6+15x12y24z\

"Note: success = 2 <==> Sagbi basi complete";
⇒ Note: success = 2 <==> Sagbi basi complete
"success",success;
⇒ success 2
```

D.15.20.2 sagbiByDegree

Procedure from library `sagbiNormaliz.lib` (see [Section D.15.20 \[sagbiNormaliz.lib\]](#), page 2587).

Usage: `sagbiByDegree(ideal Q, int sagbiDegreeBound [,int sorting, int verb]);`

Return: RETURN: An ideal whose generators form the Sagbi basis of the algebra generated by the polynomials in Q in degrees \leq `sagbiDegreeBound`.
 If sorting is set, the computed elements are degrevlex sorted before a round of the algorithm. The optional parameter `verb` sets the terminal output. Default is 1 = on.
 The component has a second integer component. Its possible values are: 0, if the full Sagbi basis has not been reached, 1 if this is unknown, and 2 if the full Sagbi basis has been computed.

Example:

```
LIB "sagbiNormaliz.lib";
ring R = 0, (x,y,z),dp;
ideal P = x^6+y^6+z^6, x^7+y^7+z^7, x^8+y^8+z^8;
ideal Q;
int success;
```

```
// degree bound 40, no sorting, no terminal output
(Q,success) = sagbiByDegree(P,40,0,0);
lead(Q);
↳ _[1]=x6
↳ _[2]=x7
↳ _[3]=x8
↳ _[4]=x8y6
↳ _[5]=x18y6
↳ _[6]=x23y7
↳ _[7]=x25y7
"Note: success = 1 <==> Unknown whether complete";
↳ Note: success = 1 <==> Unknown whether complete
"success",success;
↳ success 1
```

D.15.20.3 sagbiHilbControlled

Procedure from library `sagbiNormaliz.lib` (see [Section D.15.20 \[sagbiNormaliz.lib\]](#), page 2587).

Usage: `sagbiHilbControlled(ideal Q, intvec HS_num_algebra, intvec HS_denom_algebra, int Sagbi_degree_bound [,int finalChweck, int sorting, int verb]);`

Return: An ideal whose generators form the Sagbi basis of the algebra generated by the polynomials `inin` `degrwees` `<= Sagbi_degree_bound`. The computation is controlled by the Hilbert series given by the numerator and the denominator.

If sorting is set, the computed elements are degrevlex sorted before a round of the algorithm. The optional parameter `verb` sets the terminal output. Default is 1 = on.

The component has a second integer component. Its possible values are: 0, if the full Sagbi basis has not been reached, 1 if this is unknown, and 2 if the full Sagbi basis has been computed.

Example:

```
LIB "sagbiNormaliz.lib";
ring R = 0, (x,y,z),dp;
ideal P = x^6+y^6+z^6, x^7+y^7+z^7, x^8+y^8+z^8;
ideal Q;
intvec HS_num = 1;
intvec HS_denom = 6,7,8;
int success;
// degree bound 40, final check, ,no sorting, no terminal output
(Q,success) = sagbiHilbControlled(P,HS_num, HS_denom,40, 1,0,0);
lead(Q);
↳ _[1]=x6
↳ _[2]=x7
↳ _[3]=x8
↳ _[4]=x8y6
↳ _[5]=x18y6
↳ _[6]=x23y7
↳ _[7]=x25y7
"Note: success = 0 <==> Sagbi basis incomplete";
↳ Note: success = 0 <==> Sagbi basis incomplete
"success",success;
↳ success 0
```

D.15.21 ssi_lib

Library: ssi.lib

Purpose: Wrapper for handling SSI files in Singular

Authors: Janko Boehm, boehm@mathematik.uni-kl.de

Overview: This library provides helper functions for managing SSI files in Singular.

Procedures: See also: [Section 4.10 \[link\]](#), page 96; [Section 5.1.130 \[read\]](#), page 250; [Section 5.1.174 \[write\]](#), page 289.

D.15.21.1 openSSI

Procedure from library `ssi.lib` (see [Section D.15.21 \[ssi.lib\]](#), page 2590).

Usage: `openSSI(mode, filename);` mode string, filename string, mode is 'read', 'write', 'append', filename is the path to file

Return: a link to the opened SSI file

D.15.21.2 writeSSI

Procedure from library `ssi.lib` (see [Section D.15.21 \[ssi.lib\]](#), page 2590).

Usage: `writeSSI(l, data);` l link, data list, l is a link to an SSI file, data is a list of expressions to write

D.15.21.3 readSSI

Procedure from library `ssi.lib` (see [Section D.15.21 \[ssi.lib\]](#), page 2590).

Usage: `readSSI(l);` l link, l is a link to an SSI file

Return: the next expression from the SSI file

D.15.21.4 closeSSI

Procedure from library `ssi.lib` (see [Section D.15.21 \[ssi.lib\]](#), page 2590).

Usage: `closeSSI(l);` l = link to an SSI file

D.15.21.5 writeDataToSSI

Procedure from library `ssi.lib` (see [Section D.15.21 \[ssi.lib\]](#), page 2590).

Usage: `writeDataToSSI(filename, data);` filename string, data list, filename is the path to the SSI file, data is the list of expressions to write

Example:

```
LIB "ssi.lib";
ring R = 0, (x, y, z), dp;
writeDataToSSI("example.ssi", list(x^2, y^2, z^2, "hello world"));
```

D.15.21.6 readDataFromSSI

Procedure from library `ssi.lib` (see [Section D.15.21 \[ssi.lib\]](#), page 2590).

Usage: `readDataFromSSI(filename);` filename string, filename is the path to SSI file

Return: list of all expressions read from the file

Example:

```
LIB "ssi.lib";
ring R = 0, (x, y, z), dp;
writeDataToSSI("example.ssi", list(x^2, y^2, z^2, "hello world"));
list readData = readDataFromSSI("example.ssi");
readData;
⇒ [1]:
⇒ x2
⇒ [2]:
⇒ y2
⇒ [3]:
⇒ z2
⇒ [4]:
⇒ hello world
```

D.15.21.7 appendDataToSSI

Procedure from library `ssi.lib` (see [Section D.15.21 \[ssi.lib\]](#), page 2590).

Usage: `appendDataToSSI(filename, data);` filename string, data list, filename is the path to SSI file, data is the list of expressions to write

Example:

```
LIB "ssi.lib";
ring R = 0, (x, y, z), dp;
writeDataToSSI("example.ssi", list(x^2, y^2, z^2, "hello world"));
module M = x*gen(1), y*gen(2);
appendDataToSSI("example.ssi", list(x^3, ideal(x,y), M));
list readData = readDataFromSSI("example.ssi");
readData;
⇒ [1]:
⇒ x2
⇒ [2]:
⇒ y2
⇒ [3]:
⇒ z2
⇒ [4]:
⇒ hello world
⇒ [5]:
⇒ x3
⇒ [6]:
⇒ _[1]=x
⇒ _[2]=y
⇒ [7]:
⇒ _[1]=x*gen(1)
⇒ _[2]=y*gen(2)
```

D.15.22 stanleyreisner_lib

Library: stanleyreisner.lib

Purpose: Deformations of Stanley-Reiser ideals

Authors:

Overview: Firstly, we implement the graded pieces has certain degree of cotangent modules T_1 and T_2 for a general Stanley-Reiser ring. And the graded pieces of homomorphisms are represented by lists of integers.

Types: Homomorphism class of homomorphisms

Procedures:

D.15.22.1 T1

Procedure from library `stanleyreisner.lib` (see [Section D.15.22 \[stanleyreisner_lib\]](#), page 2592).

Usage: `T1(h);` $h = \text{ideal}$.

Assume: I is the ideal generated by the monomials w.r.t. faces.

Return: first order deformation on ideal I .

Theory: The procedure will compute the first order deformation.

Example:

```
LIB "stanleyreisner.lib";
ring R=0,(x(1..4)),lp;
ideal i=x(1),x(2),x(3),x(4),x(1)*x(4),x(2)*x(4),x(1)*x(3),x(2)*x(3);
list L=T1(i);
L;
⇒ [1]:
⇒ x(1),x(2),x(3),x(4),x(1)*x(4),x(2)*x(4),x(1)*x(3),x(2)*x(3) -> 0
⇒ phi.source -> phi.over / phi.source
⇒

D.15.22.2 T2

Procedure from library `stanleyreisner.lib` (see [Section D.15.22 \[stanleyreisner.lib\]](#), page 2592).

Usage: `T2(h)`; h = ideal.

Assume: I is the ideal generated by the monomials w.r.t. faces.

Return: second order deformation on ideal I .

Theory: The procedure will compute the second order deformation.

Example:

```
LIB "stanleyreisner.lib";
ring R=0,(x(1..4)),lp;
ideal i=x(1),x(2),x(3),x(4),x(1)*x(4),x(2)*x(4),x(1)*x(3),x(2)*x(3);
list L=T2(i);

D.15.22.3 makeQPoly

Procedure from library `stanleyreisner.lib` (see [Section D.15.22 \[stanleyreisner.lib\]](#), page 2592).

Usage: `makeQPoly(p)`; p = polynomial.

Assume: p is a polynomial in basering.

Return: a QPoly which is in a quotient ring.

Theory: The procedure will convert a polynomial in basering to a polynomial in a quotient ring.

Example:

```

LIB "stanleyreisner.lib";
ring r=0,(x,y,z),lp;
ideal i=xy;
qring Q=std(i);
poly p=x*y+z;
QPoly q=makeQPoly(p);
q.over;
⇒ // coefficients: QQ
⇒ // number of vars : 3
⇒ //          block 1 : ordering lp
⇒ //          : names  x y z
⇒ //          block 2 : ordering C
⇒ // quotient ring from ideal
⇒ _[1]=xy
q.value;
⇒ z

```

D.15.22.4 fPiece

Procedure from library `stanleyreisner.lib` (see [Section D.15.22 \[stanleyreisner.lib\]](#), page 2592).

Usage: `fPiece(I,a,b)`; I = ideal, a = poly, b = poly.

Assume: I is the ideal generated by the monomials w.r.t. faces, $a-b$ is the degree of the graded piece.

Return: graded piece (of degree $a-b$) of first order deformation on ideal I .

Theory: The procedure will compute the graded pieces of the first order deformation which has degree $a-b$.

Example:

```

LIB "stanleyreisner.lib";
ring R=0,(x(1..4)),lp;
ideal i=x(1),x(2),x(3),x(4),x(1)*x(4),x(2)*x(4),x(1)*x(3),x(2)*x(3);
FirstOrderDeformation phi=fPiece(i,x(4)^2,x(1)*x(2));
phi;
⇒ x(1),x(2),x(3),x(4),x(1)*x(4),x(2)*x(4),x(1)*x(3),x(2)*x(3) -> 1
⇒ phi.source -> phi.over / phi.source
⇒

```

D.15.22.5 sPiece

Procedure from library `stanleyreisner.lib` (see [Section D.15.22 \[stanleyreisner.lib\]](#), page 2592).

Assume: I is the ideal generated by the monomials w.r.t. faces, $a-b$ is the degree of the graded piece.

Return: graded piece (of degree $a-b$) of second order deformation on ideal I .

Theory: The procedure will compute the graded pieces of the second order deformation which has degree $(a-b)$.

Example:

```
LIB "stanleyreisner.lib";
ring R=0,(x(1..4)),lp;
ideal i=x(1),x(2),x(3),x(4),x(1)*x(4),x(2)*x(4),x(1)*x(3),x(2)*x(3);
SecondOrderDeformation psi=sPiece(i,x(4)^2,x(1)*x(2));
psi;
⇒ phi.relations -> phi.over/phi.source
⇒
```

D.15.22.6 makeLinks

Procedure from library `stanleyreisner.lib` (see [Section D.15.22 \[stanleyreisner.lib\]](#), page 2592).

Usage: `makeLinks(I,p,q)`; I = ideal, p = poly, p =poly.

Assume: I is the ideal generated by the monomials w.r.t. faces.

Return: links of p , graded pieces of first and second order deformation of links on ideal I .

Example:

```
LIB "stanleyreisner.lib";
ring R=0,(x(1..4)),lp;
ideal i=x(1),x(2),x(3),x(4),x(1)*x(4),x(2)*x(4),x(1)*x(3),x(2)*x(3);
LinksDeformation L=makeLinks(i,x(4)^2,x(1)*x(2));
L;
⇒ The links of  $x(4)^2$  is :
⇒  $\_ [1]=x(1)$ 
⇒  $\_ [2]=x(2)$ 
⇒ The first order deformation of the links is :
⇒  $x(1),x(2) \rightarrow 10$ 
⇒  $\text{phi.source} \rightarrow \text{phi.over} / \text{phi.source}$ 
⇒
⇒ The second order deformation of the links is :
⇒  $\text{phi.relations} \rightarrow \text{phi.over/phi.source}$ 
⇒
⇒
```

D.15.23 stdmodule.lib

Library: `stdmodule.lib`

Purpose: Compute Standard Bases of submodule of free module over polynomial subalgebra w.r.t Natural Grading.

Authors: Nazish Kanwal, Assistant Professor of Mathematics, Department of Sciences & Humanities, FAST-National University of Computer & Emerging Sciences-Karachi, Pakistan
Email: nkanwal@iba.edu.pk, nazish.kanwal@nu.edu.pk

Procedures:

Reference:

N, Kanwal, N, Jabeen & J. A, Khan (2021) Standard bases for modules over polynomial subalgebras, Communications in Algebra, 49:1, 58-72, DOI: 10.1080/00927872.2020.1793160

See also: [Section D.4.32 \[sagbi_lib\]](#), [page 1380](#).

D.15.23.1 MPGS

Procedure from library `stdmodule.lib` (see [Section D.15.23 \[stdmodule.lib\]](#), [page 2598](#)).

Usage: `G` free module over subalgebra `A`, `A` subalgebra(which is finite sagbi basis).

Return: a list `W`: generating set for syzygies of `G` over subalgebra `A`."

Example:

```
LIB "stdmodule.lib";
// Example 1:
ring r=QQ,(x,y),Dp;
ideal A=x2,y2;
module G=[x4+2x2y2-1,y4],[-x2y2,x2y2],[2x2y4-y2,x4y2+y6],[-x2y2,x2y6+x6y2+2x4y4];
MPGS(G,A);
⇒ [1]:
⇒ _[1]=x2*gen(2)-x2*gen(1)+y2*gen(1)-gen(3)+gen(2)
⇒ _[2]=2y4*gen(1)-x2*gen(3)+x2*gen(1)-2y2*gen(3)+2y2*gen(2)-y2*gen(1)+ge\
    n(4)-gen(2)
// Example 2:
ring r2=QQ,(x,y),Dp;
ideal A=x2-xy+y, y2+x;
module G=x2y2-xy3+x3-x2y+y3+x2+y, y4+2xy2+x2-y2-x, 2xy-2x2+2xy-2y;
MPGS(G,A);
⇒ [1]:
⇒ _[1]=gen(3)-gen(2)
⇒ _[2]=x2*gen(2)-x2*gen(1)-xy*gen(2)+xy*gen(1)-y2*gen(1)-x*gen(1)+y*gen(\
    2)-y*gen(1)
```

D.15.23.2 SNF

Procedure from library `stdmodule.lib` (see [Section D.15.23 \[stdmodule.lib\]](#), [page 2598](#)).

Usage: `SNF(f,G,A)`; `f` vector, `G` free module over `A`, `A` subalgebra (which is a finite Sagbi bases).

Return: a vector `g`: normal form of a vector `g` wrt `G` over subalgebra `A`.

Example:

```
LIB "stdmodule.lib";
ring r=0,(x,y,z),dp;
ideal A=x2-y,xz+z,y2-z;
module G=[x3z+x2z-xyz-yz,y2+xz],[y4-2y2z+z2,xy2z+y2z-xz2-z2],[x2y2-y3-x2z+yz,x4-2x2y
vector v=[x2y4-y5-2x2y2z+2y3z+x2z2-yz2-xz-z, x4y2-2x2y3-x4z+y4+2x2yz-y2z+2];
```

```

vector u=[x2y4-y5-2x2y2z+2x3z+2y3z+x2z2+2x2z-2xyz-yz2-xz-2yz-z, x4y2-2x2y3-x4z+y4+2x
SNF(v,G,A);
↦ -xz*gen(1)-z*gen(1)+2*gen(2)
SNF(u,G,A);
↦ y2*gen(2)-2xz*gen(2)-xz*gen(1)-3z*gen(2)-z*gen(1)+7*gen(2)

```

D.15.23.3 MSPOLY

Procedure from library `stdmodule.lib` (see [Section D.15.23 \[stdmodule.lib\]](#), page 2598).

Example:

```

LIB "stdmodule.lib";
// Example 1:
ring r=QQ,(x,y,z),Dp;
ideal A=x2-yz,xy+x,xz;
module G=[x2yz+x2z-2,xz+xyz2-x3z],[x3y-xy2z+x3-xyz,-1],[xy+x,x2z2-x2+yz];
MSPOLY(G,A);
↦ _[1]=-x7y*gen(1)+3x5y2z*gen(1)-x5z3*gen(2)+x4yz3*gen(1)-3x3y3z2*gen(1)+x3\
yz4*gen(2)+xy4z3*gen(1)-x7*gen(1)+3x5yz*gen(1)+x4z3*gen(1)-3x3y2z2*gen(1)\
+xy3z3*gen(1)-x6*gen(2)+x5y*gen(1)+3x4yz*gen(2)+x4z2*gen(2)-2x3y2z*gen(1)\
+x3z3*gen(2)-3x2y2z2*gen(2)-x2yz3*gen(2)+xy3z2*gen(1)+y3z3*gen(2)+x5*gen(\
1)-2x3yz*gen(1)+xy2z2*gen(1)+x4*gen(2)-2x3z*gen(1)-2x2yz*gen(2)+x2z2*gen(\
2)-2x2z2*gen(1)+2xyz2*gen(1)+y2z2*gen(2)
// Example 2:
ring r2=QQ,(x,y,z),dp;
ideal A=x2-y,xz+z,y2-z;
module G=[x2yz+x2z-2,xyz2+xz-x3z],[x3y+x3-xy2z-xyz,xz-xz-1],[xy+x,x2z2-x2+yz];
MSPOLY(G,A);
↦ _[1]=-x3z*gen(2)+x2yz*gen(1)+xyz2*gen(2)+x2z*gen(1)+xz*gen(2)-2*gen(1)
↦ _[2]=x3y*gen(1)-xy2z*gen(1)+x3*gen(1)-xyz*gen(1)-gen(2)

```

D.15.23.4 MSGB

Procedure from library `stdmodule.lib` (see [Section D.15.23 \[stdmodule.lib\]](#), page 2598).

Usage: `MSGB(G,A)`; `G` submodule over subalgebra `A`, `A` subalgebra (which is a finite sagbi basis).

Return: a module `MB`: standard bases of `G` over subalgebra `A`.

Example:

```

LIB "stdmodule.lib";
// Example 1:
ring r=ZZ,(x,y),Dp;
ideal A=2x2+xy,2y2,3xy;
ideal I=4x2y2+2xy3,18x2y4;
MSGB(I,A);
↦ _[1]=4x2y2*gen(1)+2xy3*gen(1)
↦ _[2]=18x2y4*gen(1)
// Example 2:
ring r2=QQ,(x,y),Dp;
ideal A= x2-xy+y, y2+x;
module G=x2y2-xy3+x3-x2y+y3+x2+y, y4+2xy2+x2-y2-x;
MSGB(G,A);
↦ _[1]=x2y2*gen(1)-xy3*gen(1)+x3*gen(1)-x2y*gen(1)+y3*gen(1)+x2*gen(1)+y*ge\

```

```

n(1)
⇒ _[2]=y4*gen(1)+2xy2*gen(1)+x2*gen(1)-y2*gen(1)-x*gen(1)
⇒ _[3]=2x2*gen(1)-2xy*gen(1)+2y*gen(1)
// Example 3:
ring r3=QQ,(x,y,z),Dp;
ideal A= x3-yz+2x, x2y2+xz2+3z;
module G=[x3-yz+2x, x2y2+xz2+3z, 2],[x2y2-x3+xz2+yz-2x-3z, 2x3-2yz+4x, -x2y2-xz2-3z+
MSGb(G,A);
⇒ _[1]=x2y2*gen(2)+x3*gen(1)+xz2*gen(2)-yz*gen(1)+2x*gen(1)+3z*gen(2)+2*gen\

D.15.24 swalk_lib

Library: swalk.lib

Purpose: Sagbi Walk Conversion Algorithm

Author: Junaid Alam Khan junaidalamkhan@gmail.com

Overview: A library for computing the Sagbi basis of subalgebra through Sagbi walk algorithm.

Theory: The concept of SAGBI (Subalgebra Analog to Groebner Basis for Ideals) is defined in [L. Robbiano, M. Sweedler: Subalgebra Bases, volume 42, volume 1430 of Lectures Note in Mathematics series, Springer-Verlag (1988),61-87]. The Sagbi Walk algorithm is the subalgebra analogue to the Groebner Walk algorithm which has been proposed in [S. Collart, M. Kalkbrener and D.Mall: Converting bases with the Grobner Walk. J. Symbolic Computation 24 (1997), 465-469].

Procedures: See also: [Section D.4.10 \[grwalk_lib\]](#), page 1089; [Section D.15.18 \[rwalk_lib\]](#), page 2583.

D.15.24.1 swalk

Procedure from library `swalk.lib` (see [Section D.15.24 \[swalk_lib\]](#), page 2601).

Usage: `swalk(i[,v,w]);` i ideal, v,w int vectors

Return: The sagbi basis of the subalgebra defined by the generators of i, calculated via the Sagbi walk algorithm from the ordering dp to lp if v,w are not given (resp. from the ordering (a(v),lp) to the ordering (a(w),lp) if v and w are given).

Example:

```

LIB "swalk.lib";
ring r = 0,(x,y), lp;
ideal I =x2,y2,xy+y,2xy2+y3;
swalk(I);
↪ _[1]=x2
↪ _[2]=y2
↪ _[3]=xy+y
↪ _[4]=xy2
↪ _[5]=y3

```

D.15.24.2 rswalk

Procedure from library `swalk.lib` (see [Section D.15.24 \[swalk.lib\]](#), page 2601).

Usage: `rswalk(i,weight_rad,p-deg[,v,w]);` *i* ideal, *v,w* int vectors

Return: The sagbi basis of the subalgebra defined by the generators of *i*, calculated via the Sagbi walk algorithm from the ordering *dp* to *lp* if *v,w* are not given (resp. from the ordering $(a(v),lp)$ to the ordering $(a(w),lp)$ if *v* and *w* are given).

Example:

```

LIB "swalk.lib";
ring r = 0,(x,y), lp;
ideal I =x2,y2,xy+y,2xy2+y3;
rswalk(I,2,2);
↪ _[1]=x2
↪ _[2]=y2
↪ _[3]=xy+y
↪ _[4]=xy2
↪ _[5]=y3

```

D.15.25 systhreads.lib

Library: `systhreads.lib`

Purpose: Primitives for Singular's multi-threaded objects

Author: Reimer Behrends

Overview: This library implements basic functionality for shared objects in a multi-threaded system, such as channels, shared tables & lists, and synchronization variables.

D.15.26 tateProdCplxNegGrad.lib

Library: `tateProdCplxNegGrad.lib`

Purpose: for computing sheaf cohomology on product of projective spaces

Author: Clara Petroll (petroll@mathematik.uni-kl.de)

Overview: In this library, we use Tate resolutions for computing sheaf cohomology of coherent sheaves on products of projective spaces. The algorithms can be used for arbitrary products. We work over the multigraded Cox ring and the corresponding exterior algebra. Multigraded complexes are realized as the newstruct `multigradedcomplex`.

The main algorithm is the one for computing subquotient complexes of a Tate resolution. It allows to compute cohomology tables, respectively hash table of the dimensions of sheaf cohomology groups.

References:

- [1] Eisenbud, Erman, Schreyer: Tate Resolutions for Products of Projective Spaces, Acta Mathematica Vietnamica (2015) [2] Eisenbud, Erman, Schreyer: Tate Resolutions on Products of Projective Spaces: Cohomology and Direct Image Complexes (2019)

Procedures:**D.15.26.1 productOfProjectiveSpaces**

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

Usage: `productOfProjectiveSpaces(c); c intvec`

Purpose: creates two rings S and E corresponding to the product of projective spaces $P^{c_1} \times \dots \times P^{c_t}$

Assume: input are two integers or an intvec

Return: two rings S, E (homogeneous coordinate ring and the exterior algebra of $P^{c_1} \times P^{c_2} \times \dots$)

Example:

```
LIB "tateProdCplxNegGrad.lib";
intvec c = 1,2;
def (S,E) = productOfProjectiveSpaces(c);
print(S);
⇒ polynomial ring, over a field, global ordering
⇒ // coefficients: QQ
⇒ // number of vars : 5
⇒ //      block 1 : ordering C
⇒ //      block 2 : ordering dp
⇒ //      : names      x(0)(0) x(0)(1) x(1)(0) x(1)(1) x(1)(2)
print(E);
⇒ polynomial ring, over a field, global ordering
⇒ // coefficients: QQ

D.15.26.2 truncateM

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

Usage: `truncateM(M,c);` M module, c intvec

Purpose: truncate M at c

Assume: M is multigraded S-module with S multigraded ring, c is an intvec of the right length

Return: module, the truncated module $M_{\geq c}$

Note: Output is the truncated module (multigraded, grading is not shifted), works for arbitrary products

Example:

```

LIB "tateProdCplxNegGrad.lib";
intvec c = 1,1,1;
def(S,E) = productOfProjectiveSpaces(c);
setring(S);
intmat grading[3][2] = 0,0,0,0,0,0;
module te = freemodule(2);
te = setModuleGrading(te,grading);
intvec c = 1,1,1;
↳ // ** redefining c (intvec c = 1,1,1;) ./examples/truncateM.sing:8
module Mtrunc = truncateM(te,c);
Mtrunc;
↳ Mtrunc[1]=x(0)(1)*x(1)(1)*x(2)(1)*gen(1)
↳ Mtrunc[2]=x(0)(0)*x(1)(1)*x(2)(1)*gen(1)
↳ Mtrunc[3]=x(0)(1)*x(1)(0)*x(2)(1)*gen(1)
↳ Mtrunc[4]=x(0)(0)*x(1)(0)*x(2)(1)*gen(1)
↳ Mtrunc[5]=x(0)(1)*x(1)(1)*x(2)(0)*gen(1)
↳ Mtrunc[6]=x(0)(0)*x(1)(1)*x(2)(0)*gen(1)
↳ Mtrunc[7]=x(0)(1)*x(1)(0)*x(2)(0)*gen(1)
↳ Mtrunc[8]=x(0)(0)*x(1)(0)*x(2)(0)*gen(1)
↳ Mtrunc[9]=x(0)(1)*x(1)(1)*x(2)(1)*gen(2)
↳ Mtrunc[10]=x(0)(0)*x(1)(1)*x(2)(1)*gen(2)
↳ Mtrunc[11]=x(0)(1)*x(1)(0)*x(2)(1)*gen(2)
↳ Mtrunc[12]=x(0)(0)*x(1)(0)*x(2)(1)*gen(2)
↳ Mtrunc[13]=x(0)(1)*x(1)(1)*x(2)(0)*gen(2)
↳ Mtrunc[14]=x(0)(0)*x(1)(1)*x(2)(0)*gen(2)
↳ Mtrunc[15]=x(0)(1)*x(1)(0)*x(2)(0)*gen(2)
↳ Mtrunc[16]=x(0)(0)*x(1)(0)*x(2)(0)*gen(2)
getModuleGrading(Mtrunc);
↳ 0,0,
↳ 0,0,
↳ 0,0
multiDeg(Mtrunc);
↳ 1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,

```

```

⇒ 1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,
⇒ 1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1

```

D.15.26.3 truncateCoker

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

Usage: `truncateCoker(M,c)`; M module, c intvec

Purpose: truncate cokernel `coker(M)` at the multidegree c

Return: module, which is a presentation matrix of the truncation of `coker(M)` at c

Example:

```

LIB "tateProdCplxNegGrad.lib";
// example 1
intvec c1 = 1,1,1;
def(S1,E1) = productOfProjectiveSpaces(c1);
setring(S1);
module M1= 0;
intmat grading1[3][1] = 0,0,0;
M1 = setModuleGrading(M1,grading1);
truncateCoker(M1,c1);
⇒ _[1]=x(0)(1)*gen(2)-x(0)(0)*gen(1)
⇒ _[2]=x(1)(1)*gen(3)-x(1)(0)*gen(1)
⇒ _[3]=x(1)(1)*gen(4)-x(1)(0)*gen(2)
⇒ _[4]=x(0)(1)*gen(4)-x(0)(0)*gen(3)
⇒ _[5]=x(2)(1)*gen(5)-x(2)(0)*gen(1)
⇒ _[6]=x(2)(1)*gen(6)-x(2)(0)*gen(2)
⇒ _[7]=x(0)(1)*gen(6)-x(0)(0)*gen(5)
⇒ _[8]=x(2)(1)*gen(7)-x(2)(0)*gen(3)
⇒ _[9]=x(1)(1)*gen(7)-x(1)(0)*gen(5)
⇒ _[10]=x(2)(1)*gen(8)-x(2)(0)*gen(4)
⇒ _[11]=x(1)(1)*gen(8)-x(1)(0)*gen(6)
⇒ _[12]=x(0)(1)*gen(8)-x(0)(0)*gen(7)
// example 2
intvec c2 = 1,1;
def(S2,E2) = productOfProjectiveSpaces(c2);
setring(S2);
module M2 = 0;
intmat grading2[2][1] = 0,0;
M2 = setModuleGrading(M2,grading2);
truncateCoker(M2,c2);
⇒ _[1]=x(0)(1)*gen(2)-x(0)(0)*gen(1)
⇒ _[2]=x(1)(1)*gen(3)-x(1)(0)*gen(1)
⇒ _[3]=x(1)(1)*gen(4)-x(1)(0)*gen(2)
⇒ _[4]=x(0)(1)*gen(4)-x(0)(0)*gen(3)

```

D.15.26.4 symExt

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

Usage: `symExt(m)`; m matrix

Purpose: computes differential $R(M_0) \rightarrow R(M_1)$ for the module M over S corresponding to the linear presentation matrix m , however, in order to get the result, m has to be fetched to the exterior algebra E

Assume: m a matrix, linear presentation matrix over S ; Note: also works for nonlinear matrices, but makes no sense to use it in this case

Return: matrix B representing $R(M_0) \rightarrow R(M_1)$

Note: output lives in S (not as in Macaulay2 in the ring E , to get the same result, just fetch the matrix to E)

Example:

```
LIB "tateProdCplxNegGrad.lib";
intvec c = 1,2;
def (S,E) = productOfProjectiveSpaces(c);
setring(S);
matrix m[4][2] = x(0)(0), x(1)(0), x(0)(1), 0, 0, x(1)(1), 0, x(1)(2);
matrix A = symExt(m);
print(A);
↳ 0,          x(0)(0), 0,          0,
↳ 0,          0,      x(0)(0), 0,
↳ 0,          0,          0,      x(0)(0),
↳ x(0)(1), 0,          0,          0,
↳ -x(0)(0), x(0)(1), 0,          0,
↳ 0,          0,      x(0)(1), 0,
↳ 0,          0,          0,      x(0)(1),
↳ 0,      x(1)(0), 0,          0,
↳ 0,          0,      x(1)(0), 0,
↳ 0,          0,          0,      x(1)(0),
↳ x(1)(1), 0,          0,          0,
↳ 0,      x(1)(1), 0,          0,
↳ -x(1)(0), 0,      x(1)(1), 0,
↳ 0,          0,          0,      x(1)(1),
↳ x(1)(2), 0,          0,          0,
↳ 0,      x(1)(2), 0,          0,
↳ 0,          0,      x(1)(2), 0,
↳ 0,          0,      -x(1)(1), x(1)(2)
setring(E);
print(fetch(S,A));
↳ 0,          e(0)(0), 0,          0,
↳ 0,          0,      e(0)(0), 0,
↳ 0,          0,          0,      e(0)(0),
↳ e(0)(1), 0,          0,          0,
↳ -e(0)(0), e(0)(1), 0,          0,
↳ 0,          0,      e(0)(1), 0,
↳ 0,          0,          0,      e(0)(1),
↳ 0,      e(1)(0), 0,          0,
↳ 0,          0,      e(1)(0), 0,
↳ 0,          0,          0,      e(1)(0),
↳ e(1)(1), 0,          0,          0,
↳ 0,      e(1)(1), 0,          0,
↳ -e(1)(0), 0,      e(1)(1), 0,
↳ 0,          0,          0,      e(1)(1),
↳ e(1)(2), 0,          0,          0,
```

$$\begin{array}{lll} \mapsto 0, & e(1)(2), 0, & 0, \\ \mapsto 0, & 0, & e(1)(2), 0, \\ \mapsto 0, & 0, & -e(1)(1), e(1)(2) \end{array}$$

D.15.26.5 sufficientlyPositiveMultidegree

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

Usage: `sufficientlyPositiveMultidegree(M);` M module

Purpose: computes a sufficiently positive multidegree for `coker(M)`

Assume: M is multigraded S-module

Return: intvec that is sufficiently positive for M

Example:

```
LIB "tateProdCplxNegGrad.lib";
// example 1
intvec c1 = 1,2;
def (S1,E1) = productOfProjectiveSpaces(c1);
setring(S1);
module M1 = x(0)(0),x(1)(0)^3 + x(1)(1)^3 +x(1)(2)^3;
intmat grading1[2][1] = 0,0;
M1 = setModuleGrading(M1,grading1);
sufficientlyPositiveMultidegree(M1);
↦ 1,3
// example 2
intvec c2 = 1,1;
def (S2,E2) = productOfProjectiveSpaces(c2);
setring(S2);
intmat grading2[2][1] = -1,-1;
module M2 = 0;
M2 = setModuleGrading(M2,grading2);
sufficientlyPositiveMultidegree(M2);
↦ -1,-1
// example 3
intvec c3 = 1,1,1;
def (S3,E3) = productOfProjectiveSpaces(c3);
setring(S3);
module M3 = 0;
intmat grading3[3][1] = -1,-1,-1;
M3 = setModuleGrading(M3,grading3);
sufficientlyPositiveMultidegree(M3);
↦ -1,-1,-1
```

D.15.26.6 tateResolution

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

Usage: `tateResolution(M,low,high);` M module, L list, low intvec, high intvec

Purpose: compute tate resolution of `coker(M)` where M is \mathbb{Z}^t -graded S-module

Assume: M a module over multigraded ring S

Return: (E, tate) , tate a multigradedcomplex, E the ring in which tate has to be viewed, however note that tate is not ring dependent

Example:

```
LIB "tateProdCplxNegGrad.lib";
// example 1
intvec c1 = 1,1,1;
intvec low1 = 0,0,0;
intvec high1 = 0,1,0;
def (S1,E1) = productOfProjectiveSpaces(c1);
setring(S1);
module M1 = 0;
intmat grading1[3][1] = -1,-1,-1;
M1 = setModuleGrading(M1,grading1);
multigradedcomplex tate1;
(E1,tate1) = tateResolution(M1,low1,high1);
setring(E1);
tate1;

D.15.26.7 cohomologyMatrix

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

Usage: `cohomologyMatrix(M,L,low,high)`; M module, L list, low intvec, high intvec

Purpose: computes the cohomology matrix of the sheaf corresponding to `coker(M)`

Assume: M module over S, L list of two rings S and E (e.g. result of `productOfProjectiveSpaces`)
first entry `L[1] = S` and `L[2] = E`, integer vectors `low <= high`

Return: ring Z in which cohomology matrix lives, it is exported in the variable `cohomologymat`,
`cohomologymat` covers all cohomology groups of twists in the range between low and high

Example:

```

LIB "tateProdCplxNegGrad.lib";
// example 1
intvec c1 = 1,1;
def (S1,E1) = productOfProjectiveSpaces(c1);
intvec low1 = -3,-3;
intvec high1 = 3,3;
setring(S1);
module M1 = 0;
intmat grading1[2][1] = -1,-1;
M1 = setModuleGrading(M1,grading1);
ring Z1 = cohomologyMatrix(M1,low1,high1);

```

```

setring(Z1);
print(cohomologymat);

```

D.15.26.8 cohomologyMatrixFromResolution

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

- Usage:** `cohomologyMatrixFromResolution(T,low,high);` `T` multigraded complex, `low` intvec, `high` intvec
- Purpose:** computes the cohomology matrix corresponding to the multigraded complex `T` (part of a Tate resolution)
- Assume:** `T` is a multigraded complex representing a part of a Tate resolution (for example output of `tateResolution`), basering is `E`
- Return:** ring `Z` in which cohomology matrix lives, it is exported in the variable `cohomologymat`, `cohomologymat` stores information in the range between `low` and `high`

Example:

```

LIB "tateProdCplxNegGrad.lib";
intvec c = 1,1;
def (S,E) = productOfProjectiveSpaces(c);
intvec low = -3,-3;
intvec high = 3,3;
setring(S);
module M = 0;
intmat grading[2][1] = -1,-1;
M = setModuleGrading(M,grading);
multigradedcomplex tate;
(E,tate) = tateResolution(M,low,high);
setring(E);
ring Z = cohomologyMatrixFromResolution(tate,low,high);
setring(Z);
print(cohomologymat);

↪ h, 0,1,2, 3, 4, 5,
↪ 0, 0,0,0, 0, 0, 0,
↪ h2,0,h,2h,3h,4h,5h

```

D.15.26.9 eulerPolynomialTable

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

Usage: `eulerPolynomialTable(M,low,high)`; M module, L list, low intvec, high intvec

Purpose: computes hash table of euler polynomials of twists of `coker(M)` in the range between low and high

Assume: M module, note that at the moment M is a module over S,

Return: `(Z,eulerpolynomialtable)`, where `eulerpolynomialtable` is a hash table with entries in the ring $Z = \mathbb{Z}\mathbb{Z}[h]$

Note: this function works for arbitrary products $P^{\{n_1\}} \times \dots \times P^{\{n_t\}}$ and corresponding \mathbb{Z}^t -gradings, entries can be accessed via `eulerpolynomialtable*(a_1,...,a_t)` where $a=(a_1,...,a_t)$ is a multidegree between low and high

Example:

```

LIB "tateProdCplxNegGrad.lib";
// example 1
intvec c1 = 1,1;
def (S1,E1) = productOfProjectiveSpaces(c1);
intvec low1 = -3,-3;
intvec high1 = 3,3;
setring(S1);
module M1 = 0;
intmat grading1[2][1] = -1,-1;
M1 = setModuleGrading(M1,grading1);
def (Z1,eulerTable1) = eulerPolynomialTable(M1,low1,high1);
setring(Z1);
print(eulerTable1);

```

D.15.26.10 cohomologyHashTable

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

- Usage:** `cohomologyHashTable(M,L,low,high)`; M module, low intvec, $high$ intvec
- Purpose:** computes hashtable of sheaf cohomology groups of twists in the range between low and $high$ corresponding to `coker(M)`
- Assume:** M module representing a sheaf F on the product of t projective spaces, note that at the moment M is a module over S ,
- Return:** `cohomologytable` where `cohomologytable` is a hash table with integer vectors in \mathbb{Z}^{t+1} as keys, entries can be accessed via `cohomologytable*(c_1,...,c_t,i) = dim(H^i(F(c_1,...,c_t)))`
- Note:** this function works for arbitrary products $P^{\{n_1\}} \times \dots \times P^{\{n_t\}}$ and corresponding \mathbb{Z}^t -gradings

Example:

```

LIB "tateProdCplxNegGrad.lib";
intvec c = 1,1;
def (S,E) = productOfProjectiveSpaces(c);
intvec low = -3,-3;

```

```

intvec high = 3,3;
setring(S);
module M = 0;
intmat grading[2][1] = -1,-1;
M = setModuleGrading(M,grading);
def cohomologytable = cohomologyHashTable(M,low,high);
print(cohomologytable);

D.15.26.11 twist

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

Usage: `twist(M,c)`; M module, c intvec

Purpose: twists the module M by c

Assume: M is a multigraded module

Return: M with the new grading

Example:

```
LIB "tateProdCplxNegGrad.lib";
intvec c = 1,1;
def (S,E) = productOfProjectiveSpaces(c);
setring(S);
module M = freemodule(2);
intmat gradeM[2][2] = 0,1,0,1;
M = setModuleGrading(M,gradeM);
getModuleGrading(M);
↪ 0,1,
↪ 0,1
intvec c = 2,2;
↪ // ** redefining c (intvec c = 2,2;) ./examples/twist.sing:9
module Mtwist = twist(M,c);
getModuleGrading(Mtwist);
↪ -2,-1,
↪ -2,-1
```

D.15.26.12 beilinsonWindow

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

Usage: `beilinsonWindow(T);` T multigradedcomplex

Purpose: compute the subquotient complex of T consisting of summands generated in degrees $0 \leq a \leq n$

Assume: T is a multigraded complex of free E -modules

Return: multigradedcomplex, the Beilinson window of T

Note: The returned summands are the only ones that contribute to the Beilinson monad.

Example:

```
LIB "tateProdCplxNegGrad.lib";
intvec f = 1,1;
def (S,E) = productOfProjectiveSpaces(f);
intvec low = -3,-3;
intvec high = 3,3;
setring(S);
module M = 0;
intmat MGrading[2][1] = -1,-1;
M = setModuleGrading(M,MGrading);
multigradedcomplex tate;
(E,tate) = tateResolution(M,low,high);
setring(E);
multigradedcomplex W = beilinsonWindow(tate);
W;
↪ 0 <-- E^4 <-- E^4 <-- E^1 <-- 0
↪ -1 0 1 2 3
```

```

↳
intvec c = 1,1,1;
intvec low2 = 0,0,0;

def (S2,E2) = productOfProjectiveSpaces(c);
setring(S2);
module M2 = 0;
intmat gradeM[3][1] = -1,-1,-1;
M2 = setModuleGrading(M2,gradeM);
multigradedcomplex tate2;
(E2,tate2) = tateResolution(M2,low2,high2);
setring(E2);
multigradedcomplex W2 = beilinsonWindow(tate2);
W2;
↳ 0 <-- E^8
↳ -1      0
↳

```

D.15.26.13 regionComplex

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

Usage: `regionComplex(T,d,I,J,K)`; T multigradedcomplex, d intvec, I intvec, J intvec, K intvec

Purpose: compute the region complex of T w.r.t. the sets I,J,K and the vector d

Assume: I,J,K are intvecs representing disjoint subsets of $\{1,\dots,t\}$, T is a complex in ring E, zero represents the empty set

Return: multigraded complex which is the region complex $T_{\mathbf{d}}(I,J,K)$ of T

Example:

```

LIB "tateProdCplxNegGrad.lib";
intvec f = 1,1;
def (S,E) = productOfProjectiveSpaces(f);
intvec low = -3,-3;
intvec high = 3,3;
setring(S);
module M = 0;

D.15.26.15 firstQuadrantComplex

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

Usage: `firstQuadrantComplex(T,c);` T multigradedcomplex, c intvec

Purpose: compute the first quadrant complex of T w.r.t. the set J and the vector c

Return: subquotient complex of T which is the first quadrand complex of T

D.15.26.16 lastQuadrantComplex

Procedure from library `tateProdCplxNegGrad.lib` (see [Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602).

Usage: `lastQuadrantComplex(T,c);` T multigradedcomplex, c intvec

Purpose: compute the last quadrant complex of T w.r.t. the set J and the vector c

Return: subquotient complex of T which is the strand of T

D.15.27 transformation_lib

Library: `transWithPrecision.lib`

Purpose: The image of a transformation given up to a specified degree

Authors: Janko Boehm, email: boehm@mathematik.uni-kl.de
 Magdaleen Marais, email: msmarais@sun.ac.za
 Alexander Mathis

Overview: The image of a map defined by a matrix is given up to a specified degree. This tool can be used, particularly in Singularity theory, working with right equivalence.

It is known that a nondegenerate germ which has finite determinacy d is right equivalent to its d -jet. Therefore, in these cases, it is often enough to know the image of a transformation up to degree d .

Procedures:

D.15.27.1 transWithPrecision

Procedure from library `transformation.lib` (see [Section D.15.27 \[transformation.lib\]](#), page 2622).

Usage: `transWithPrecision(f,T,d);` f poly, T $1 \times n$ matrix, where n is the number of variables of the basering, d int

Return: the image of f under the transformation defined by T up to degree d

Example:

```
LIB "transformation.lib";
ring R=0,(x,y,z),ds;
poly f = 2*x^2+5*x*y+7*x^7;
matrix T[1][3]=x+2*y+y^2,y+x^2*y,z+y^2+z^2*x;
transWithPrecision(f,T,7);
↦ 2x2+13xy+18y2+4xy2+13y3+5x3y+10x2y2+2y4+5x2y3+7x7+98x6y+588x5y2+1960x4y3+
3920x3y4+4704x2y5+3136xy6+896y7
```

D.15.28 tropicalEllipticCovers.lib

Library: `tropicalEllipticCovers.lib`

Purpose: Gromov-Witten numbers of tropical elliptic curves and their covers

Authors: J. Boehm, boehm @ mathematik.uni-kl.de
 F. Dastur, dastur.firoozeh @ gmail.com

Overview: We implement a formula for computing the number of covers of (abstract) elliptic curves with and without tangency conditions, and for the surface Exp1 . For the first case, we have used methods discussed in [BGM1]. For the covers without tangency conditions, we obtain the covers of an elliptic curve using tropical methods in [BBM], and for Exp1 , we have used the concepts from [BGM2]. A Feynman graph G of genus g is a trivalent, connected graph (of genus g) with n number of vertices and r number of edges (in case of abstract elliptic curve in [BBM] we have $2g-2$ vertices and $3g-3$ edges, since we consider only trivalent graphs). A pearl chain P of type (d_2, g) is a genus g , connected graph of degree d_2 such that it has two different types of vertices, say vertices of type w and b (where w represent the white vertices and b the black ones). Every edge in P connect vertex of type w to vertex of type b such that the vertices adjacent to each edge are not of the same type. There are precisely d_2 vertices of type w and d_2+g-1 vertices of type b . The vertices of type b should be 2-valent and the vertices of type w can have any valency. For each case we compute the respective propagator function from which we later

use terms to compute the Gromov-Witten invariants $N_-(g,d)$, $N_-(g,d,\Omega)$ and $N_-(P,d_1,d_2,g)$.

Types: graph,number,list,poly,string

Procedures:

D.15.28.1 cf_of

Procedure from library `tropicalEllipticCovers.lib` (see [Section D.15.28 \[tropicalEllipticCovers.lib\]](#), page 2623).

Usage: `cf_of(f,g);` f poly, g poly

Assume: f is a polynomial, g is a monomial

Return: poly.

Theory: For a given polynomial f, it computes the coefficient of g in f

Example:

```
LIB "tropicalEllipticCovers.lib";
ring r=0,(x1,x2,x3,x4),dp;
poly f=3*x1^6+11*x1^4*x2^2+x1^2*x2^4+3*x2^6;
cf_of(f,x1^4*x2^2);
```

D.15.28.2 preim

Procedure from library `tropicalEllipticCovers.lib` (see [Section D.15.28 \[tropicalEllipticCovers.lib\]](#), page 2623).

Usage: `preim(O, x);` O list, x poly/number

Assume: O is a list of ordering of the set of vertices (or indices of the vertices), x is a monomial representing a vertex of a graph (or the index of the vertex we are interested in).

Return: int.

Theory: This gives the entry number of x in list O.

Example:

```
LIB "tropicalEllipticCovers.lib";
ring r=0,(x1,x2,x3,x4),dp;
preim(list(x1,x3,x4,x2),x2);
```

D.15.28.3 coverTuple

Procedure from library `tropicalEllipticCovers.lib` (see [Section D.15.28 \[tropicalEllipticCovers.lib\]](#), [page 2623](#)).

Usage: `coverTuple(G,aa,O,t[,l]);` G graph, aa list, O list, t int, l list

Assume: G is a Feynman graph, aa is a partition of the degree of the graph G, O is a given ordering of the vertices of G, t is an integer and l is a list of leaks in G.

Return: list.

Theory: Computes a list of tuples (depending on the int t) of the form (a_k, N_k, D_k) for all k=1,...,r, where r is the number of edges, a_k is the k-th entry in the partition aa of the degree of G, N_k and D_k are the corresponding numerator and denominator (respectively) of the propagator function whose product would return the coefficient of the Feynman integral.

Every list of the tuples corresponds to a cover of the elliptic curve E. (For t=0, we get the results for simply ramified covers [BBM]. t=1, 2 we get results for graphs w/o vertex contributions respectively w/ vertex contributions as in [BGM1], and for t=3 we get the results for pearl chains as in [BGM2])

Example:

```
LIB "tropicalEllipticCovers.lib";
ring r=0, (x1,x2,x3,z1,z2,z3),dp;
graph F=makeGraph(list(1,2,3),list(list(1,1),list(1,2),list(2,3),list(1,3)));
coverTuple(F,list(1,0,0,2),list(x1,x2,x3),2,list(0,0,0));
```

D.15.28.4 CoverMult

Procedure from library `tropicalEllipticCovers.lib` (see [Section D.15.28 \[tropicalEllipticCovers.lib\]](#), [page 2623](#)).

Usage: `CoverMult(G,aa,O,t[,l]);` G graph, aa list, O list, t int, l list

Assume: G is a Feynman graph, aa is a partition of the degree of the graph G, O is a given ordering of the vertices of G, l is a list of leaks of G and t is some integer between 0 and 3.

Return: list.

Theory: For a given ordering of the vertices of G, this function computes a list of multiplicity for each cover of G. Each entry in the list is a multiplicity of a cover of G. (For t=0, we get the results for simply ramified covers [BBM]. t=1, 2 we get results for graphs w/o vertex contributions respectively w/ vertex contributions as in [BGM1], and for t=3 we get the results for pearl chains as in [BGM2])

Example:

```
LIB "tropicalEllipticCovers.lib";
ring r=0, (x1,x2,x3,x4),dp;
graph G=makeGraph(list(1,2,3,4),list(list(1,3),list(1,2),list(1,2),list(2,4),list(3,4)));
CoverMult(G,list(0,2,1,0,0,1), list(x2,x4,x3,x1),0);
```

D.15.28.5 Tropicalcover

Procedure from library `tropicalEllipticCovers.lib` (see [Section D.15.28 \[tropicalEllipticCovers.lib\]](#), page 2623).

Usage: `Tropicalcover(G,aa,O,t[, l]);` G graph, aa list, O list, t int, l list

Assume: G is a Feynman graph, aa is a partition of the degree of the graph G, O is a given ordering of the vertices of G, t is an integer and l is a list of leaks of G.

Return: list of matrices.

Theory: For a given ordering of the vertices of G, this function computes a list of matrices such that each matrix in the list represents a cover of the elliptic curve E. The first column of each matrix shows how many points on each edge of the cover (of type G) has a preimage of the base point p_0 . The rows of the matrix represents an edge of the cover and each non-zero entry in a row represents a vertex connected to that edge.
(For $t=0$, we get the results for simply ramified covers [BBM]. $t=1, 2$ we get results for graphs w/o vertex contributions respectively w/ vertex contributions as in [BGM1], and for $t=3$ we get the results for pearl chains as in [BGM2])

Example:

```
LIB "tropicalEllipticCovers.lib";
ring r=0, (x1,x2,x3,x4),dp;
graph G=makeGraph(list(1,2,3,4),list(list(1,3),list(1,2),list(1,2),list(2,4),list(3,4)),list(1,2,3,4));
Tropicalcover(G,list(0,2,1,0,0,1), list(x2,x4,x3,x1),0);
```

D.15.28.6 sinh

Procedure from library `tropicalEllipticCovers.lib` (see [Section D.15.28 \[tropicalEllipticCovers.lib\]](#), page 2623).

Usage: `sinh(t,n);` t poly, n int

Assume: t is a polynomial and n is a non-zero integer

Return: poly

Theory: Returns the power series expansion of the hyperbolic sine function up to n terms.

Example:

```
LIB "tropicalEllipticCovers.lib";
ring R=0,(x,y),dp;
sinh(x,5); // expands sine hyperbolic function for variable x to first 5 terms
```

D.15.28.7 Sfunction

Procedure from library `tropicalEllipticCovers.lib` (see [Section D.15.28 \[tropicalEllipticCovers.lib\]](#), page 2623).

Usage: `Sfunction(z,k);` z poly, k int

Assume: z is a polynomial and k is an integer

Return: poly

Theory: Returns the S-function in the form of $(1+X)$, where X is a Taylor series expansion of the sinh function upto k terms.

Example:

```
LIB "tropicalEllipticCovers.lib";
ring R=0,(x,y),dp;
Sfunction(x,3);
```

D.15.28.8 FloorDiagrams

Procedure from library `tropicalEllipticCovers.lib` (see [Section D.15.28 \[tropicalEllipticCovers.lib\]](#), page 2623).

Usage: FloorDiagrams(G,aa,O,Lw,n); G graph, aa list, O list, Lw list, n int

Assume: G is a pearl chain of the degree d , aa is a partition of degree d , O is an ordering of the vertices of G, Lw is a list where the first n terms represent the leaks in G and the next $d2$ terms is a list of white pearls (assuming the first pearl is always white). NOTE: Requires `pdflatex` to be installed.

Return: Latex file.

Theory: If $n=0$: the procedure generates a Latex file for all the tropical stable maps to Exp1 and if $n=1$: the procedure generates the source file that can be executed in Latex to get all the stable maps of Exp1 (in the form of floor diagrams) for every curled pearl chain of an elliptic curve E provided similar information.

Example:

```
LIB "tropicalEllipticCovers.lib";
ring R=0,(x1,x2,x3,x4,x5),dp;
graph P=makeGraph(list(1,2,3,4,5),list(list(1,2),list(1,3),list(3,4),list(2,4),list(4,5)),list(1,2,3,4,5));
//graph P is a pearl chain
FloorDiagrams(P,list(0,0,2,0,0,1),list(x5,x4,x2,x1,x3),list(0,0,0,0,0,1,4),0);
```

D.15.28.9 PropagatorFunction

Procedure from library `tropicalEllipticCovers.lib` (see [Section D.15.28 \[tropicalEllipticCovers.lib\]](#), page 2623).

Usage: PropagatorFunction(G,aa,O,t[,l]); G graph, aa list, O list, t int, l list

Assume: G is a graph (a Feynman graph or a pearl chain) of the degree d , aa is a partition of degree d , O is an ordering of the vertices of G, l is a list representing the leaky edges of G and t is one of 0,1,2 or 3.

Return: list P_t of propagator function for each edge of G as follows: P_0: Propagator for a Feynman graph G as in [BBM], i.e., a graph without any self-looping edges, leaks or vertex contributions.

P_1: Propagator for a Feynman graph G without vertex contributions as in [BGM1], i.e., A graph that may have self-looping edges and leaks. P_2: Propagator for a Feynman graph G with vertex contributions as in [BGM1] possibly with self-looping edges and leaks.

P_3: Propagator for a pearl chain G as in [BGM2], i.e., graph G may have leaks.

Theory: Computes the numerator and the denominator of the propagator function for every edge of graph G depending on the integer t .

Example:

```
LIB "tropicalEllipticCovers.lib";
ring r1=0, (x1,x2,x3,x4),dp;
graph G = makeGraph(list(1,2,3,4),list(list(1,3),list(1,2),list(1,2),list(2,4),list(
PropagatorFunction(G,list (0,2,1,0,0,1), list (x1,x3,x4,x2),0);
//This is another example:
ring r2=0,(x1,x2,x3,z1,z2,z3),dp;
graph GG = makeGraph(list(1,2,3),list(list(1,1),list(1,2),list(2,3),list(3,1)));
PropagatorFunction(GG,list(1,0,0,3),list(x1,x2,x3),1);
//Yet another example
ring r3=0,(x1,x2,x3,x4,x5),dp;
graph P=makeGraph(list(1,2,3,4),list(list(1,2),list(2,3),list(3,4),list(4,1)));
//graph P is a pearl chain
PropagatorFunction(P, list (1,0,0,1),list (x1,x2,x3,x4),3);
```

D.15.28.10 FeynmanIntegralo

Procedure from library `tropicalEllipticCovers.lib` (see [Section D.15.28 \[tropicalEllipticCovers.lib\]](#), page 2623).

Usage: `FeynmanIntegralo(G,aa,O,l,k,t[gg]);` G graph, aa list, O list, l list, k int, t int, gg list

Assume: G is a graph (a Feynman graph or a pearl chain) of the degree d , aa is a partition of degree d , O is an ordering of the vertices of G , l is a list representing the leaky edges of G , k is any integer, gg is a list representing the genus function and t is one of 0,1,2 or 3.

Return: number or list Q_t (depending on k) of Feynman integral for a fixed ordering of vertices of G , the results are as follows:

Q_0 : Feynman integral for a fixed ordering of a Feynman graph G as in [BBM], i.e., a graph without any self-looping edges, leaks or vertex contributions. Q_1 : Feynman integral for a fixed ordering of a Feynman graph G without vertex contributions as in [BGM1], i.e. A graph that may have self-looping edges and leaks.

Q_2 : Feynman integral for a fixed ordering of a Feynman graph G with vertex contributions as in [BGM1] possibly with self-looping edges and leaks. Q_3 : Feynman integral for a fixed ordering of a pearl chain G as in [BGM2], i.e., graph G may have leaks.

Theory: If k is zero it returns the coefficient of the Feynman integral for a given ordering of the vertices of the graph G . Otherwise, returns a list showing the ordering and the coefficient of the Feynman integral for the corresponding ordering.

Example:

```
LIB "tropicalEllipticCovers.lib";
ring r1=0, (x1,x2,x3,x4),dp;
graph G = makeGraph(list(1,2,3,4),list(list(1,3),list(1,2),list(1,2),list(2,4),list(
FeynmanIntegralo(G,list (0,2,1,0,0,1), list (x1,x3,x4,x2),list(0,0,0,0,0,0),1,0);
//This is another example:
ring r2=0,(x1,x2,x3,z1,z2,z3),dp;
graph GG = makeGraph(list(1,2,3),list(list(1,1),list(1,2),list(2,3),list(3,1)));
FeynmanIntegralo(GG, list (2,0,0,1), list (x1,x2,x3),list (0,0,0), 0,1);
//Yet another example
```

```

ring r3=0,(x1,x2,x3,x4,x5),dp;
graph P=makeGraph(list(1,2,3,4),list(list(1,2),list(2,3),list(3,4),list(4,1)));
//graph P is a pearl chain
FeynmanIntegralO(P,list (1,0,0,1),list (x1,x2,x3,x4), list (0,0,0,0), 0,3);

```

D.15.28.11 FeynmanIntegralO

Procedure from library `tropicalEllipticCovers.lib` (see [Section D.15.28 \[tropicalEllipticCovers.lib\]](#), page 2623).

Usage: `FeynmanIntegralO(G,aa,l,k,t[gg]);` G graph, aa list, l list, k int, t int, gg list

Assume: G is a graph (a Feynman graph or a pearl chain) of the degree d, aa is a partition of degree d, l is a list representing the leaky edges of G, k is any integer, gg is a list representing the genus function and t is one of 0,1,2 or 3.

Return: number or list Q_t (depending on k) of Feynman integral for all possible orderings of vertices of G, the results are as follows: Q_0 : Feynman integral for all orderings of a Feynman graph G as in [BBM], i.e., a graph without any self-looping edges, leaks or vertex contributions. Q_1 : Feynman integral for all orderings of a Feynman graph G without vertex contributions as in [BGM1], i.e. A graph that may have self-looping edges and leaks. Q_2 : Feynman integral for all orderings of a Feynman graph G with vertex contributions as in [BGM1] possibly with self-looping edges and leaks. Q_3 : Feynman integral for all orderings of a pearl chain G as in [BGM2], i.e., a graph G may have leaks.

Theory: If k is zero it returns the coefficient which is a sum of Feynman integrals over all orderings of the vertices of the graph G. Otherwise, returns a list showing the ordering, the coefficient of the Feynman integral for the corresponding ordering and the sum.

Example:

```

LIB "tropicalEllipticCovers.lib";
ring r1=0, (x1,x2,x3,x4),dp;
graph G = makeGraph(list(1,2,3,4),list(list(1,3),list(1,2),list(1,2),list(2,4),list(3,4)));
FeynmanIntegralO(G,list (0,2,1,0,0,1),list (0,0,0,0,0,0),1,0);

```

D.15.28.12 FeynmanIntegralA

Procedure from library `tropicalEllipticCovers.lib` (see [Section D.15.28 \[tropicalEllipticCovers.lib\]](#), page 2623).

Usage: `FeynmanIntegralA(G,O,d,l,k,t[gg]);` G graph, O list, d int, l list, k int, t int, gg list

Assume: G is a graph (a Feynman graph or a pearl chain) of the degree d, O is an ordering of vertices of G, d is the degree of G, l is a list representing the leaky edges of G, k is any integer, gg is a list representing the genus function and t is one of 0,1,2 or 3.

Return: number or list Q_t (depending on k) of Feynman integral for a fixed ordering of vertices of G, the results are as follows:
 Q_0 : sum of Feynman integrals (over all partitions of d) for a fixed ordering of a Feynman graph G as in [BBM], i.e. a graph without any self-looping edges, leaks or vertex contributions.
 Q_1 : sum of Feynman integrals (over all partitions of d) for a fixed ordering of a

Feynman graph G without vertex contributions as in [BGM1], i.e. A graph that may have self-looping edges and leaks.

Q_2: sum of Feynman integrals (over all partitions of d) for a fixed ordering of a Feynman graph G with vertex contributions as in [BGM1] possibly with self-looping edges and leaks.

Q_3: sum of Feynman integrals (over all partitions of d) for a fixed ordering of a pearl chain G as in [BGM2], i.e. graph G may have leaks.

Theory: If k is zero it returns the coefficient which is a sum of Feynman integrals over all partitions of d . Otherwise, returns a list showing the partition from which the Feynman integral is computed, the respective coefficient of the Feynman integral for the given ordering and the sum over all partitions.

Example:

```
LIB "tropicalEllipticCovers.lib";
ring r1=0, (x1,x2,x3,x4),dp;
graph G = makeGraph(list(1,2,3,4),list(list(1,3),list(1,2),list(1,2),list(2,4),list(
FeynmanIntegralA(G,list(x1,x3,x4,x2),4,list(0,0,0,0,0,0),0,0);
```

D.15.28.13 DrawCovers

Procedure from library `tropicalEllipticCovers.lib` (see [Section D.15.28 \[tropicalEllipticCovers.lib\]](#), page 2623).

Usage: DrawCovers($G,aa,O,t[,lw]$); G graph, aa list, O list, t int, n int and lw list

Assume: G is a Feynman graph/pearl chain, aa is a partition of the degree of the graph G , O is a given ordering of the vertices of G , t is an integer between 0 and 3 and lw is a list where the first n entries represent the leaks in G and the remaining terms tells us about the white pearls of G . NOTE: Requires pdflatex to be installed.

Return: if $n=0$: C_t is a Latex file generating all the covers of an elliptic curve and if $n=1$: C_t is the source file that can be executed in Latex to get the covers of an elliptic curve (given an ordering O and a partition aa). The results for C_t are as follows:
 C_0 : returns a Latex file drawing all simply ramified covers of an elliptic curve given a fixed ordering of the vertices of G and a fixed partition of its degree. C_1 : returns a Latex file drawing all covers of an elliptic curve such that G has no vertex contributions, given a fixed ordering of the vertices of G and a fixed partition of its degree.
 C_2 : returns a Latex file drawing all covers of an elliptic curve such that G has vertex contributions, given a fixed ordering of the vertices of G and a fixed partition of its degree.
 C_3 : returns a Latex file drawing all curled pearl chains of an elliptic curve given a fixed ordering of the vertices of G and a fixed partition of its degree.

Theory: For a given ordering of the vertices of G , this function computes Latex file drawing all the covers of an elliptic curve E . If G is a pearl chain then this procedure draws the black and white pearls of G accordingly using information from list lw .
(For $t=0$, we get the results for simply ramified covers as in [BBM]. For $t=1, 2$ we get results for graphs w/o vertex contributions respectively w/ vertex contributions as in [BGM1], and for $t=3$ we get the results for pearl chains as in [BGM2])

Example:

```
LIB "tropicalEllipticCovers.lib";
```

```

ring r1=0, (x1,x2,x3,x4),dp;
graph G=makeGraph(list(1,2,3,4),list(list(1,3),list(1,2),list(1,2),list(2,4),list(3,4)),list(0,2,1,0,0,1),list(x2,x4,x3,x1),0,0);
//This is another example:
ring r2=0,(x1,x2,x3,z1,z2,z3),dp;
//F is graph with loops
graph F=makeGraph(list(1,2,3),list(list(1,1),list(1,2),list(2,3),list(1,3)));
DrawCovers(F,list(1,0,0,2),list(x1,x2,x3),2,0,list(0,0,0));
//Yet another example
ring r3=0,(x1,x2,x3,x4,x5),dp;
//in P vertices 1 and 3 are white, genus 2
graph P=makeGraph(list(1,2,3,4,5),list(list(1,2),list(2,3),list(3,4),list(1,4),list(1,5)),list(0,0,0,1,2,0),list(x1,x2,x3,x4,x5),3,1,list(0,0,0,0,0,1,3));
DrawCovers(P,list(0,0,0,1,2,0),list(x1,x2,x3,x4,x5),3,1,list(0,0,0,0,0,1,3));

```

D.15.28.14 TropCovandMaps

Procedure from library `tropicalEllipticCovers.lib` (see [Section D.15.28 \[tropicalEllipticCovers.lib\]](#), page 2623).

Usage: TropCovandMaps(G,aa,O,Lw,n); G graph, aa list, O list, Lw list, n int

Assume: G is a pearl chain, aa is a partition of the degree of the graph G, O is a given ordering of the vertices of G, Lw is a list of leaks and white vertices in G. NOTE: Requires `pdflatex` to be installed.

Return: Depending on n this procedure returns either a pdf or a latex file for the curled pearl chains of an elliptic curve and their corresponding stable maps of Exp1 for a fixed ordering of the vertices of the source curve and a fixed partition of its degree.

Theory: For a given ordering of the vertices of G, this function computes a list of commands that can be executed in TikZ. Each list represents a cover of the elliptic curve E and its corresponding stable map of Exp1 . Since G is a pearl chain this procedure draws the black and white pearls of G accordingly using information from list lw.

Example:

```

LIB "tropicalEllipticCovers.lib";
ring r=0,(x1,x2,x3,x4,x5),dp;
graph P=makeGraph(list(1,2,3,4,5),list(list(1,2),list(2,3),list(3,4),list(4,1),list(1,5)),list(0,0,0,1,2,0),list(x1,x2,x3,x4,x5),3,1,list(0,0,0,0,0,1,3));
graph P1=makeGraph(list(1,2,3,4),list(list(1,2),list(2,3),list(3,4),list(4,1)));
//graphs P and P1 are pearl chains
TropCovandMaps(P,list(0,0,0,1,2,0),list(x1,x2,x3,x4,x5),list(0,0,0,0,0,1,3), 0);

```

D.15.29 VecField.lib

Library: VecField.lib

Purpose: vector fields, with algorithms for jordan and diagonal forms

Authors: Adrian Rettich, rettich@mathematik.uni-kl.de
Raul Epure, epure@mathematik.uni-kl.de

References:

[1] Kyoji Saito, Quasihomogene isolierte Singularitaeten von Hyperflaechen, 1971

Overview: Implements a class `VecField`, represented by a vector. For example, `'VecField V = [x3,xy]'` declares the vector field $v = x^3 d_x + xy d_y$. Instead of a vector, an $n \times 1$ matrix is also accepted. The vector can be recovered as `V.vec`.

Supports coordinate transformations (via maps), which are represented by tracking a map `'V.coordinates'` which maps the standard coordinates to those in which `V` is currently represented. `V.dimension` stores the vector field's dimension, which is just `nvars(basing)`, and `V.lin` yields the linear part of `V`. You may set an additional parameter `V.precision`, which dictates the degree to which operations on the vector field should be exact.

The default precision is 1. Precision is preserved across transformations, additions, and all other manipulations of vector fields.

Procedures:

D.15.29.1 `applyVecField`

Procedure from library `VecField.lib` (see [Section D.15.29 \[VecField.lib\]](#), page 2631).

Usage: `applyVecField(VecField V, poly/ideal p [,int n])`

Return: if `p` is a polynomial, return a polynomial `V(p)`, if `p` is an ideal, the ideal `V(p)`. If an optional `n` is given, only the parts of `V` up to and including degree `n` are applied to `p`.

Example:

```
LIB "VecField.lib";
int oldp = printlevel;
printlevel = 1;
ring r = 0, (x, y, z), ds;
vector v = [-1,-1,-1];
VecField V = v;
poly f = x3+2y3+xz2;
poly g = V*f;
ideal I = (x2,y);
ideal J = V*I;
printlevel = oldp;
```

D.15.29.2 `changeCoordinates`

Procedure from library `VecField.lib` (see [Section D.15.29 \[VecField.lib\]](#), page 2631).

Usage: `changeCoordinates(vecField V, map psi)`, where `psi` is an algebra morphism $k[x_1, \dots, x_n] \rightarrow k[y_1, \dots, y_m]$ expressing the new basis in terms of the old.

Return: A new vecfield in the new coordinates.

Note: the coordinate change necessitates inverting `psi`.
The inversion will be correct up to the precision of `V`.

Example:

```
LIB "VecField.lib";
ring r = 0, (x, y, z), ds;
vector v = [-1,-1,-1];
VecField V = v;
V.precision = 4;
map phi = r, x-2y2+z3, 2y+y3+z, z;
VecField W = changeCoordinates(V, phi);
```

D.15.29.3 jordanVecField

Procedure from library `VecField.lib` (see [Section D.15.29 \[VecField.lib\]](#), page 2631).

Usage: `jordanVecField(VecField V)`

Return: new vecfield `W` in coordinates s.t. `W.lin` is in Jordan normal form.

Assume: eigenvalues of `V.lin` in basefield.

Example:

```
LIB "VecField.lib";
ring r = 0, (x, y, z), ds;
vector v = [-1,-1,-1];
VecField V = v;
V.precision = 4;
map phi = r, x-2y2+z3, 2y+y3+z, z;
VecField W = changeCoordinates(V, phi);
VecField X = jordanVecField(W);
```

D.15.29.4 diagonalizeVecFieldLin

Procedure from library `VecField.lib` (see [Section D.15.29 \[VecField.lib\]](#), page 2631).

Usage: `diagonalizeVecFieldLin(list l)`, where `l` is a list of `VecFields`

Return: list `W` of the same `VecFields` in new coords s.t. the linear parts are diagonal, all in the same coordinates

Assume: All linear parts of the entries of `l` are simultaneously diagonalizable.

Example:

```
LIB "VecField.lib";
ring r = 0, (x, y, z), ds;
vector v = [-1,-1,-1];
VecField V = v;
V.precision = 4;
map phi = r, x-2y2+z3, 2y+y3+z, z;
VecField W = changeCoordinates(V, phi);
VecField X = [-2,1,0];
list d = diagonalizeVecFieldLin(W,X);
```

D.15.29.5 SaitoBase

Procedure from library `VecField.lib` (see [Section D.15.29 \[VecField.lib\]](#), page 2631).

Usage: `SaitoBase(VecField V)`

Return: new `VecField W` in the base from [1] thm. 3.1, where semisimple and nilpotent components are easily read off.

Note: the algorithm requires inversions of algebra morphisms. These will be exact to the precision of `V`. Warning: The algorithm assumes standard coordinates. If `V` is not given in standard coordinates, it will be converted to standard coordinates, but not converted back at the end, so the resulting transformation is from standard coordinates to the Saito coordinates. If you want the entire transformation from your original coordinates to the Saito ones, add the inverse of your original coordinate transformation manually. Note that weight vectors only take `Int64`, making the algorithm fail for very large entries in `V.vec`.

Example:

```

LIB "VecField.lib";
ring r = 0, (x, y, z), ds;
vector v = [-1,-1,-1];
VecField V = v;
V.precision = 4;
map phi = r, x-2y2+z3, 2y+y3+z, z;
VecField W = changeCoordinates(V, phi);
VecField WS = SaitoBase(W);

```

D.15.29.6 diagonalizeVecField

Procedure from library `VecField.lib` (see [Section D.15.29 \[VecField.lib\]](#), page 2631).

Usage: `diagonalizeVecField(list l)`, `l` a list of `VecFields`

Return: list of `VecFields` `W` such that they are all simultaneously diagonal.

Assume: all input `VecFields` have to be simultaneously diagonalizable.

Note: the algorithm requires inversions of algebra morphisms. These will be exact to the precision of `l[1]`. Warning: The algorithm assumes standard coordinates. If `V` is not given in standard coordinates, it will be converted to standard coordinates, but not converted back at the end, so the resulting transformation is from standard coordinates to the Saito coordinates. If you want the entire transformation from your original coordinates to the Saito ones, add the inverse of your original coordinate transformation manually.

Note that weight vectors only take `Int64`, making the algorithm fail for very large entries in `V.vec`.

Example:

```

LIB "VecField.lib";
int oldp = printlevel;
printlevel = 1;
ring r = 0, (x, y, z), ds;
vector v = [-1,-1,-1];
VecField V = v;
V.precision = 4;
map phi = r, x-2y2+z3, 2y+y3+z, z;
VecField W = changeCoordinates(V, phi);
VecField X = [-2,1,0];
VecField WS = diagonalizeVecField(W,X);
↳ ? error in diagonalizeVecField: no solutions found
↳ ? leaving VecField.lib::diagonalizeVecField (0)
printlevel = oldp;

```

D.15.29.7 vecFieldToMatrix

Procedure from library `VecField.lib` (see [Section D.15.29 \[VecField.lib\]](#), page 2631).

Usage: `vecFieldToMatrix(VecField V, ideal W)`

Return: the matrix representation of `V` restricted to `span(W)`, in the basis specified by `W`.

Example:

```

LIB "VecField.lib";
int oldp = printlevel;
printlevel = 1;
ring r = 0, (x, y, z), ds;
vector v = [-1,-1,-1];
VecField V = v;
V.precision = 4;
map phi = r, x-2y2+z3, 2y+y3+z, z;
VecField W = changeCoordinates(V, phi);
matrix m = vecFieldToMatrix(W, maxideal(2));
printlevel = oldp;

```

D.15.29.8 decomposeVecField

Procedure from library `VecField.lib` (see [Section D.15.29 \[VecField.lib\]](#), page 2631).

- Usage:** `decomposeVecField(VecField V)` or `decomposeVecField(list s)`, `s` a list of `VecFields`
- Return:** list `l` containing two `VecFields`, where `l[1]` is the semisimple part of `V`, `l[2]` the nilpotent part. If called with a list, `l[2n-1]` is the semisimple part of the `n`-th `VecField`, `l[2n]` its nilpotent part.
- Assume:** The algorithm assumes standard coordinates. If `V` is not given in standard coordinates, it will be converted to standard coordinates, but not converted back at the end, so the resulting transformation is from standard coordinates to the new coordinates. If you want the entire transformation from your original coordinates to the new ones, add the inverse of your original coordinate transformation manually.

Example:

```

LIB "VecField.lib";
ring r = 0, (x, y, z), ds;
vector v = [-1,-1,-1];
VecField V = v;
V.precision = 4;
map phi = r, x-2y2+z3, 2y+y3+z, z;
VecField W = changeCoordinates(V, phi);
list l = decomposeVecField(W);

```

D.15.29.9 diagonalizeMatrixSimul

Procedure from library `VecField.lib` (see [Section D.15.29 \[VecField.lib\]](#), page 2631).

- Usage:** `diagonalizeMatrixSimul(list l)`, where `l` is a list of quadratic matrices of same dimensions
- Return:** trafo matrix `U` s.t. $U \cdot A \cdot \text{inv}(U)$ is diagonal for each `A` in `l`
- Assume:** matrices are simultaneously diagonalizable, `nvars(basering) ≥ dimension of the matrices`

Example:

```

LIB "VecField.lib";
ring r = 0, (x(1), x(2), x(3), x(4)), dp;
matrix a[4][4] = 2, 0, 0, 0, 0, 3, 0, 0, 0, 0, 3, 0, 0, 0, 0, 5;
matrix b[4][4] = 6, 0, 0, 0, 0, 6, 0, 0, 0, 0, 2, 0, 0, 0, 0, 7;
matrix trafo[4][4] = 3, 3, 0, 0, 0, 1, 3, 0, 2, 0, 1, 0, 0, 2, 2, 3;
matrix invtrafo = inverse(trafo);

```

```

matrix at = invtrafo * a * trafo;
matrix bt = invtrafo * b * trafo;
list l;
l = insert(l,at);
l = insert(l,bt);
matrix diagtrafo = diagonalizeMatrixSimul(l);

```

D.15.29.10 invertAlgebraMorphism

Procedure from library `VecField.lib` (see [Section D.15.29 \[VecField.lib\]](#), page 2631).

Usage: `invertAlgebraMorphism(map p,int n)`, where `p` is an algebra morphism $k[x_1,\dots,x_n] \rightarrow k[y_1,\dots,y_m]$,
 or `invertAlgebraMorphism(ideal p,int n)` if you represent the map as an ideal

Return: the inverse of `p` mod $(\text{maxideal})^n$.
 If `n=-1`, try for infinite precision. If input was an ideal, return an ideal.

Note: the algorithm used is described in [1], chapter 3.2

Example:

```

LIB "VecField.lib";
ring r = 0, (x, y, z), ds;
vector v = [-1,-1,-1];
VecField V = v;
V.precision = 4;
map phi = r, x-2y2+z3, 2y+y3+z, z;
map phiinv = invertAlgebraMorphism(phi,4);

```

8 Release Notes

8.1 News and changes

NEWS in SINGULAR 4.4.0

News for version 4.4.0

New libraries:

`arnold.lib`: Classification of isolated singularities with a nondegenerate Newton Boundary ([Section D.15.1 \[arnold.lib\]](#), page 2277)

`transformation.lib`: The image of a transformation given up to a specified degree ([Section D.15.27 \[transformation.lib\]](#), page 2622)

Changed libraries:

`polyclass.lib`: extended ([Section D.15.15 \[polyclass.lib\]](#), page 2573)

Changes in the kernel/build system:

use new algorithm for weighted Hilbert function [Section 5.1.56 \[hilb\]](#), page 195

use new algorithm for [Section 5.1.151 \[std\]](#), page 271 in the case of ordering `ds` and zero dimensional ideal over `QQ`

changed reduction routine for local orderings

News for version 4-4-0

New libraries:

`modfinduni.lib`: parallel computation of finduni ([Section D.15.11 \[modfinduni.lib\]](#), page 2482 [Section 5.1.43 \[finduni\]](#), page 185)

`sagbiNormaliz.lib`: computation of Sagbi bases via normaliz ([Section D.15.20 \[sagbiNormaliz.lib\]](#), page 2587)

`stdmodule.lib`: Compute Standard Bases of submodule of free module over polynomial subalgebra ([Section D.15.23 \[stdmodule.lib\]](#), page 2598)

`tropicalEllipticCovers.lib`: Gromov-Witten numbers of tropical elliptic curves and their covers ([Section D.15.28 \[tropicalEllipticCovers.lib\]](#), page 2623)

Changed libraries:

`normal.lib`: optimized, integrated `locnorma.lib` and `modnormal.lib` ([Section D.4.23 \[normal.lib\]](#), page 1185)

`normaliz.lib`: update to normaliz 3.10 ([Section D.4.24 \[normaliz.lib\]](#), page 1213)

`hess.lib`: fixes ([Section D.5.7 \[hess.lib\]](#), page 1453)

`sheafcoh.lib`: new routines [Section D.5.18.5 \[sheafCohBGGregul\]](#), page 1614, [Section D.5.18.6 \[sheafCohBGGregul_w\]](#), page 1615, [Section D.5.18.9 \[sheafCoh_w\]](#), page 1622, ([Section D.5.18 \[sheafcoh.lib\]](#), page 1609)

`sheafcoh.lib`: display of the tables is moved to [Section D.5.18.12 \[displayCohom\]](#), page 1624 ([Section D.5.18 \[sheafcoh.lib\]](#), page 1609)

`elim.lib`: rename `sat` to `sat_with_exp`, `sat` now return the saturation `i9deal` (only).

`primdec.lib`: fixed a bug in absolute primary decomposition ([Section D.4.26 \[primdec.lib\]](#), [page 1243](#))

New type:

`bigintvec`: [Section 4.4 \[bigintvec\]](#), [page 78](#)

New commands:

new command [Section 5.1.123 \[prune_map\]](#), [page 245](#)

new command [Section 5.1.99 \[mres_map\]](#), [page 226](#)

New/renamed monomial orderings:

To avoid confusion (with the degree reverse lexicographic ordering) the orderings `rp` and `rs` are renamed:

renamed orderings `rp` -> `ip` `rs` -> `is`

new ordering `Ip`

Changes in the kernel/build system:

new algorithm for [Section 5.1.151 \[std\]](#), [page 271](#) in the case of ordering `ds` and zero dimensional ideal over `QQ`

new algorithm for lift function ([Section 5.1.80 \[lift\]](#), [page 211](#))

`mstd` for local rings ([Section 5.1.100 \[mstd\]](#), [page 227](#))

use the new Hilbert function algorithm for [Section 5.1.56 \[hilb\]](#), [page 195](#). (Different output format/ different return type)

renamed orderings `ringorder_rp` -> `ringorder_ip` `ringorder_rs` -> `ringorder_is`

new ordering `ringorder_Ip`

changes for FLINT 3.0.x/3.1.x

News for version 4-3-2

Changed libraries:

many: call `std` in many places only if attribute `isSB` is not set

many: change many calls to `execute` by better variants

New commands:

`coeffs` for `ring` ([Section 5.1.12 \[coeffs\]](#), [page 165](#))

Changes in the kernel/build system:

new algorithm for Hilbert function ([Section 5.1.56 \[hilb\]](#), [page 195](#))

News for version 4-3-1

New libraries:

`normal.lib`: new command `isNormal`, option `normalCheck` for `normal` ([Section D.4.23 \[normal.lib\]](#), [page 1185](#))

Changed libraries:

`chern.lib`: fixed `symNsym` ([Section D.5.2 \[chern.lib\]](#), [page 1395](#))

`homolog.lib`: fixed corner cases for `depth` ([Section D.4.11 \[homolog.lib\]](#), [page 1092](#))

New commands:

`chinrem`, `farey` for `smatrix` ([Section 4.21 \[smatrix\]](#), page 129)

Changed commands:

overflow check for [Section 5.1.168 \[vdim\]](#), page 286

Hilbert function ([Section 5.1.56 \[hilb\]](#), page 195) cannot overflow (different return type)

`delete` accepts `intvec` for the indices to delete ([Section 5.1.21 \[delete\]](#), page 171)

several GB based commands accept the choice of the algorithm: `"std"`, `"slimgb"`, `"sba"`, `"modstd"`, `"singmatic"`, `"groebner"`, `"ffmod"`, `"nfmmod"` ([Section 5.1.156 \[syz\]](#), page 280, [Section 5.1.28 \[eliminate\]](#), page 176, [Section 5.1.65 \[intersect\]](#), page 202, [Section 5.1.94 \[modulo\]](#), page 223, [Section 5.1.81 \[liftstd\]](#), page 212, [Section 5.1.80 \[lift\]](#), page 211)

`reduce` for non-field coefficients: search best reduction

Changes in the kernel/build system:

changes for gcc 12

new option `--log LOGFILE`

configure can change the path to hml documentation (`--htmldir=...`)

different format for `doc.tbz2`

new algorithm for Hilbert function ([Section 5.1.56 \[hilb\]](#), page 195)

News for version 4-3-0

New libraries:

`enumpoints.lib`: enumerating rational points ([Section D.15.4 \[enumpoints.lib\]](#), page 2371)

`sagbigrob.lib`: Sagbi-Groebner basis of an ideal of a subalgebra ([Section D.15.19 \[sagbigrob.lib\]](#), page 2585)

`puiseuxexpansion.lib`: Puiseux expansions over algebraic extensions ([Section D.15.16 \[puiseux-expansions.lib\]](#), page 2578)

`integralbasis.lib`: Integral basis in algebraic function fields: new version ([Section D.4.12 \[integralbasis.lib\]](#), page 1116)

Changes in the kernel/build system:

input history is stored by default in `.singularhistory` ([Section 3.1.5 \[Editing input\]](#), page 18).

ABI change: all number routines (`n_...`) have only `coeffs` as last argument, functions with `ring` as last argument are removed

`PATH` is not changed for `system("sh",...)` (use `<undefined> [system, SingularBin]`, page `<undefined>`)

`hilb` avoids int overflow (also in `degree`, `stdhilb`)

`liftstd` (with 2 arguments) improved ([Section 5.1.81 \[liftstd\]](#), page 212)

`noether` improved ([Section 5.3.5 \[noether\]](#), page 304), use in `groebner(I,"HC")` for faster results for local orderings, 0-dimensional ideals ([Section 5.1.53 \[groebner\]](#), page 191).

letterplace routines improved ([Section 7.7 \[LETTERPLACE\]](#), page 617)

info file is now `singular.info` instead of `singular.hlp`

update for using FLINT 2.8.x

News for version 4-2-1

New commands:

- Letterplace: `dim`, `rightStd` for `qrings` ([Section 7.7 \[LETTERPLACE\]](#), page 617)
- Letterplace: `map`, `fetch`, `imap` ([Section 4.12 \[map\]](#), page 106, [Section 5.1.38 \[fetch\]](#), page 182, [Section 5.1.59 \[imap\]](#), page 198)

New libraries:

- `decomp.lib`: functional decomposition of polynomials ([Section D.4.6 \[decomp.lib\]](#), page 1052)
- `hodge.lib`: algorithms for Hodge ideals ([Section D.15.8 \[hodge.lib\]](#), page 2464)
- `tateProdCplxNegGrad.lib`: sheaf cohomology on product of projective spaces ([Section D.15.26 \[tateProdCplxNegGrad.lib\]](#), page 2602)

Changes in the kernel/build system:

- `liftstd` (with 2 arguments) improved ([Section 5.1.81 \[liftstd\]](#), page 212)
- building on Cygwin with shared libraries
- building the manual via `--enable-doc-build`

News for version 4-2-0

Syntax changes:

- renamed `poly.lib` to `polylib.lib` ([Section D.2.8 \[polylib.lib\]](#), page 889)

New libraries:

- `interval.lib`: interval arithmetic ([Section D.8.2 \[interval.lib\]](#), page 1829)
- `maxlike.lib`: algebraic statistics ([Section D.15.10 \[maxlike.lib\]](#), page 2477)
- `nchilbert.lib`: Hilbert series for LetterPlace algebras ([Section 7.5.13 \[nchilbert.lib\]](#), page 518)
- `polyclass.lib`: class of polynomials ([Section D.15.15 \[polyclass.lib\]](#), page 2573)
- `recover.lib`: Hybrid numerical/symbolical algorithms ([Section D.8.7 \[recover.lib\]](#), page 1866)
- `redcgs.lib`: Reduced Comprehensive Groebner Systems ([Section D.2.9 \[redcgs.lib\]](#), page 898)
- `ringgb.lib`: coefficient rings ([Section D.15.17 \[ringgb.lib\]](#), page 2581)
- `sets.lib`: Sets ([Section D.14.8 \[sets.lib\]](#), page 2272)
- `stanleyreisner.lib`: T1 and T2 for a general Stanley-Reiser ring ([Section D.15.22 \[stanleyreisner.lib\]](#), page 2592)
- `systhreads.lib`: multi-threaded objects ([Section D.15.25 \[systhreads.lib\]](#), page 2602)

Changed libraries:

- `classify_aeq.lib`: new procedure `classSpaceCurve` ([Section D.6.6 \[classify_aeq.lib\]](#), page 1661)
- `grobcov.lib`: new version ([Section D.2.4 \[grobcov.lib\]](#), page 818)
- `modular.lib`: parallel version for verification via `system("verifyGB",I)`

New commands:

- `system("verifyGB",I)`: test, if I is a Groebner basis (using parallel processes)
- Letterplace: `modulo`, `syz`, `lift`, `liftstd`, `rightStd` ([Section 7.7 \[LETTERPLACE\]](#), page 617)

Changes in the kernel/build system:

- update for using FLINT 2.6.x and for FLINT 2.7.0
- Singular can be build with NTL or FLINT or both (if none is available, `factorize` and `gcd` will not work.)

News for version 4-1-3

New libraries:

- invar.lib: Invariant theory [Section D.7.4 \[invar_lib\]](#), page 1817
- moddiq.lib: ideal quotient and saturation [Section D.4.14 \[moddiq_lib\]](#), page 1122
- ncModslimgb.lib: modular Groebner bases for G-algebras [Section 7.5.18 \[ncModslimgb_lib\]](#), page 554

Changed libraries:

- chern.lib: new version ([Section D.5.2 \[chern_lib\]](#), page 1395)
- grobcov.lib: new version ([Section D.2.4 \[grobcov_lib\]](#), page 818), new functions [Section D.2.4.22 \[ConsLevels\]](#), page 870, [Section D.2.4.23 \[Levels\]](#), page 872, [Section D.2.4.24 \[Grob1Levels\]](#), page 873, [Section D.2.4.25 \[DifConsLCSets\]](#), page 876

Changes in the kernel/build system:

- improved gcd and multiplication via FLINT
- improved lift (and related)
- port to polymake 3.5.x
- rational functions via flint ([Section 5.1.44 \[flintQ\]](#), page 185)
- free algebra over \mathbb{Z} ([Section 7.7 \[LETTERPLACE\]](#), page 617)
- adaptions/functions for Singular.jl(<https://github.com/oscar-system/Singular.jl>)

News for version 4-1-2

New libraries:

- arnoldclassify.lib: Arnol'd Classifier of Singularities ([Section D.6.3 \[arnoldclassify_lib\]](#), page 1644)
- difform.lib: Procedures for differential forms ([Section D.15.3 \[difform_lib\]](#), page 2334)
- dmodideal.lib: Algorithms for Bernstein-Sato ideals of morphisms ([Section 7.5.6 \[dmodideal_lib\]](#), page 447)
- fpalgebras.lib: Generation of various algebras in the letterplace case ([Section 7.10.2 \[fpalgebras_lib\]](#), page 646)
- ncrat.lib: non-commutative rational functions ([Section 7.10.6 \[ncrat_lib\]](#), page 676)

Changed libraries:

- freegb.lib: lpDivision, lpPrint ([Section 7.10.4 \[freegb_lib\]](#), page 666)
- fpadim.lib ([Section 7.10.1 \[fpadim_lib\]](#), page 640)
- schreyer.lib: deprecated
- goettsche.lib: new, extended version (The Nakajima-Yoshioka formula up to n-th degree, Poincare Polynomial of the punctual Quot-scheme of rank r on n planar points Betti numbers of the punctual Quot-scheme of rank r on n planar points)([Section D.5.5 \[goettsche_lib\]](#), page 1441)
- grobcov.lib: small bug fix ([Section D.2.4 \[grobcov_lib\]](#), page 818)

Changes in the kernel/build system:

- integrated xalloc into omalloc: (`./configure --disable-omalloc`)
- improved heuristic for `det` ([Section 5.1.23 \[det\]](#), page 172)
- improved reading of long polynomials

improved groebner bases over \mathbb{Z} coefficients

code for free algebras (letterplace rings) rewritten (using now the standard `+, -, *, ^, std, ...`) ([Section 7.7 \[LETTERPLACE\]](#), page 617)

new commands `rightstd` ([Section 7.8.10 \[rightstd \(letterplace\)\]](#), page 633)

extended `twostd` to LETTERPLACE ([Section 7.8.14 \[twostd \(letterplace\)\]](#), page 635, [Section 7.3.29 \[twostd \(plural\)\]](#), page 364)

pseudo type `polyBucket`

new type `smatrix`: sparse matrix (experimental) ([Section 4.21 \[smatrix\]](#), page 129).

extended `coef` to ideals ([Section 5.1.11 \[coef\]](#), page 164).

error and signal handling in `libSingular` ([Section 8.3 \[libSingular\]](#), page 2649).

updated `gfanlib` to version 0.6.2

port to NTL 11 (needs C++11: `gcc6` or `-std=c++11`), which does not conflict with `polymake` (needs C++14)

News for version 4-1-1

New syntax:

`alias`: may be used as a prefix to a variable declaration. Can only be used in procedure headings. ([Section 3.5.1 \[General command syntax\]](#), page 41).

New command:

`fres`: improved version of `sres`: computes a (not necessarily minimal) free resolution of the input ideal/module, using Schreyer's algorithm. ([Section 5.1.48 \[fres\]](#), page 188, [Section 5.1.149 \[sres\]](#), page 269).

Extended commands:

pseudo ordering `L` allows setting of limits for exponents in polynomials ([Section B.2.9 \[Pseudo ordering L\]](#), page 774, [Section 5.1.2 \[attrib\]](#), page 156 for `maxExp`)

`%,mod`: also for poly operands ([Section 4.17.3 \[poly operations\]](#), page 121).

`delete`: extended to `intvec`, `ideal`, `module` ([Section 5.1.21 \[delete\]](#), page 171).

`syz` ([Section 5.1.156 \[syz\]](#), page 280), `lift` ([Section 5.1.80 \[lift\]](#), page 211), `liftstd` ([Section 5.1.81 \[liftstd\]](#), page 212), `intersect` ([Section 5.1.65 \[intersect\]](#), page 202): with a specified GB algorithm

New libraries:

`classify2.lib`: Classification of isolated singularities of corank ≤ 2 and modality \leq wrt. right equivalence over the complex numbers according to Arnold's list. ([Section D.6.5 \[classify2.lib\]](#), page 1659)

`goettsche.lib`: Goettsche's formula for the Betti numbers of the Hilbert scheme of points on a surface, Macdonald's formula for the symmetric product ([Section D.5.5 \[goettsche.lib\]](#), page 1441)

`combinat.lib`, `modules.lib`, `methods.lib`, `nets.lib`: a more mathematical view of modules ([Section D.14.2 \[combinat.lib\]](#), page 2236: combinatorics), ([Section D.14.4 \[methods.lib\]](#), page 2242: construct procedures), ([Section D.4.15 \[modules.lib\]](#), page 1124: free resolutions), ([Section D.14.5 \[nets.lib\]](#), page 2243: pretty printing)

`ncHilb.lib`: Hilbert series of non-commutative monomial algebras ([Section 7.10.5 \[ncHilb.lib\]](#), page 673)

`realclassify.lib`: Classification of real singularities ([Section D.6.19 \[realclassify.lib\]](#), page 1750)

rootisolation.lib: real root isolation using interval arithmetic([Section D.8.8 \[rootisolation_lib\]](#), [page 1894](#))

rstandard.lib: Janet bases and border bases for ideals ([Section D.4.31 \[rstandard_lib\]](#), [page 1270](#))

Changed libraries:

chern.lib: new version ([Section D.5.2 \[chern_lib\]](#), [page 1395](#))

gitfan.lib: new (incompatible) version ([Section D.13.3 \[gitfan_lib\]](#), [page 2093](#))

grobcov.lib: new version ([Section D.2.4 \[grobcov_lib\]](#), [page 818](#))

Changes in the kernel/build system:

port to polymake 3.x.x

port to NTL 10 with threads (needs also C++11: gcc6 or -std=c++11)

p_Invers is only a helper for p_Series: now static

p_Divide is now p_MDivide, pDivide/p_Divide is a new routine

News for version 4-1-0

Syntax changes:

new (additional) form of ring definitions: (for example `ring R=QQ[x,y,z];`) ([Section 3.3.2 \[General syntax of a ring declaration\]](#), [page 32](#))

new (additional) form of multi-indicies: (for example `i(1,2,3,4,5)`) ([Section 3.5.3 \[Names\]](#), [page 44](#))

changed behaviour of `charstr` ([Section 5.1.7 \[charstr\]](#), [page 162](#))

new data type `cring` to describe the coefficient rings, to be used for the new definitions for (polynomial) rings ([Section 3.3.2 \[General syntax of a ring declaration\]](#), [page 32](#))

new command `ring_list` to access the parts used to construct polynomial rings ([Section 5.1.138 \[ring_list\]](#), [page 257](#), [Section 5.1.137 \[ringlist\]](#), [page 255](#))

extended polynomial ring construction: also from lists produced by `ring_list`

new attribute `ring_cf` for `ring` ([Section 5.1.2 \[attrib\]](#), [page 156](#))

printing of rings changed to match `cring` names ([Section 5.1.7 \[charstr\]](#), [page 162](#))

New libraries:

new library: `classifyMapGerms.lib`: standard basis of the tangent space at the orbit of an algebraic group action ([Section D.6.9 \[classifyMapGerms_lib\]](#), [page 1667](#))

new library: `ffmodstd.lib`: Groebner bases of ideals in polynomial rings over algebraic function fields([Section D.4.9 \[ffmodstd_lib\]](#), [page 1082](#))

new library: `nfmodsyz.lib`: syzygy modules of submodules of free modules over algebraic number fields([Section D.4.21 \[nfmodsyz_lib\]](#), [page 1179](#))

new library: `curveInv.lib`: invariants of curves ([Section D.4.5 \[curveInv_lib\]](#), [page 1049](#))

new library: `gfan.lib`: interface to `gfanlib` ([Section D.13.2 \[gfan_lib\]](#), [page 2053](#))

extended library: interface to polymake merged into [Section D.13.4 \[polymake_lib\]](#), [page 2132](#)

new library: `tropicalNewton.lib`: Newton polygon methods in tropical geometry ([Section D.13.7 \[tropicalNewton_lib\]](#), [page 2199](#))

new library: `schubert.lib`: some procedures for intersection theory ([Section D.5.17 \[schubert_lib\]](#), [page 1590](#))

Changed libraries:

- classify_aeq.lib: new procedures ([Section D.6.6 \[classify_aeq_lib\]](#), page 1661)
- grobcov.lib: new version ([Section D.2.4 \[grobcov_lib\]](#), page 818)
- ncfactor.lib: factorization in some noncommutative algebras ([Section 7.5.12 \[ncfactor_lib\]](#), page 487) with new routine ncfactor ([Section 7.5.12.1 \[ncfactor\]](#), page 487)
- primdec.lib: new option "subsystem" ([Section D.4.26 \[primdec_lib\]](#), page 1243)

Changes in the kernel:

- improved mapping of polynomials/ideals/...
- port to gcc 6
- port to gfanlib 0.6 (requires C++11, i.e. gcc >=4.3)
- port to NTL 10
- port to polymake 3.0
- port to readline 7
- [Section 5.1.140 \[sba\]](#), page 259 works for global orderings, also for coefficient types \mathbb{Z} and \mathbb{Z}/m
- [Section 5.1.151 \[std\]](#), page 271 works for all orderings, also for coefficient types \mathbb{Z} and \mathbb{Z}/m with local/mixed orderings
- [Section 5.1.36 \[factorize\]](#), page 180 works for polynomial rings over $\mathbb{Z}\mathbb{Z}$

Experimental stuff:

- module [Section D.14.3 \[customstd_lib\]](#), page 2241: modify `std` ([Section D.14.3.2 \[satstd\]](#), page 2242)

News for version 4-0-3

New libraries:

- new library: brillnoether.lib: Riemann-Roch spaces of divisors on curves ([Section D.5.1 \[brill-noether_lib\]](#), page 1394)
- new library: chern.lib: Chern classes ([Section D.5.2 \[chern_lib\]](#), page 1395)
- new library: fmodstd.lib: Groebner bases of ideals in polynomial rings over algebraic function fields ([Section D.4.9 \[fmodstd_lib\]](#), page 1082)
- new library: GND.lib: General Neron Desingularization ([Section D.15.6 \[GND_lib\]](#), page 2385)
- new library: graal.lib: localization at prime ideals ([Section D.5.6 \[graal_lib\]](#), page 1448)
- new library: hess.lib: Riemann-Roch space of divisors ([Section D.5.7 \[hess_lib\]](#), page 1453)

Changed libraries:

- renamed algeomodstd.lib to [Section D.4.20 \[nfmodstd_lib\]](#), page 1176, extended to module
- renamed derham.lib to [Section D.5.3 \[deRham_lib\]](#), page 1431
- grobcov.lib (grobcovK): Groebner Cover for parametric ideals ([Section D.2.4 \[grobcov_lib\]](#), page 818) with new routine ConsLevels ([Section D.2.4.22 \[ConsLevels\]](#), page 870), removed AddCons AddConsP.

News for version 4-0-2

New commands:

`align` ([Section 5.1.1 \[align\]](#), page 156)
`branchTo` ([Section 4.18.3 \[procs with different argument types\]](#), page 125)
`->` ([Section 4.18.2 \[proc expression\]](#), page 125)

Change in ring handling:

`typeof(qring)` returns "ring"

New libraries:

`algemodstd.lib`: Groebner bases of ideals in polynomial rings over algebraic number fields (renamed to [Section D.4.20 \[nfmodstd.lib\]](#), page 1176)
`arr.lib`: arrangements of hyperplanes ([Section D.14.1 \[arr.lib\]](#), page 2208)
`brillnoether.lib`: Riemann-Roch spaces of divisors on curve ([Section D.5.1 \[brillnoether.lib\]](#), page 1394)
`hess.lib`: Riemann-Roch space of divisors on function fields and curves ([Section D.5.7 \[hess.lib\]](#), page 1453)
`gradedModules.lib`: graded modules/matrices/resolutions ([Section D.15.7 \[gradedModules.lib\]](#), page 2388)

Changed libraries:

revised `polymake` interface (`polymake.so`)
revised `gfanlib` interface (`gfanlib.so`)
`Presolve::findvars` ([Section D.8.3.6 \[findvars\]](#), page 1838, [Section 5.1.166 \[variables\]](#), page 285)
`Ring::addvarsTo` ([Section D.2.12.26 \[addvarsTo\]](#), page 957)
`Ring::addNvarsTo` ([Section D.2.12.27 \[addNvarsTo\]](#), page 958)
`Ring::hasAlgExtensionCoefficient` ([Section D.2.12.21 \[hasAlgExtensionCoefficient\]](#), page 956)
`Schreyer::s_res` (`s_res`)
`grobcov.lib` (`grobcovK`) ([Section D.2.4 \[grobcov.lib\]](#), page 818) with new routines `AddCons` `AddConsP`.
`normaliz.lib` (for `normaliz >= 2.8`) ([Section D.4.24 \[normaliz.lib\]](#), page 1213)
renamed `groeberFan` to `groeberFanP` in `polymake.lib` ([Section D.13.4 \[polymake.lib\]](#), page 2132)
renamed `fVector` to `fVectorP` in `polymake.lib` ([Section D.13.4 \[polymake.lib\]](#), page 2132, `polymakeInterface.lib`)

News for version 4-0-1

Version 4-0-1 is a bug fix release.

New feature: attribute `ring_cf` for `ring` ([Section 5.1.2 \[attrib\]](#), page 156)

News for version 4-0-0

Version 4-0-0 is a milestone release of Singular. The new release series 4 aims for an entirely modularized architecture simplifying connectivity with other systems and paving the way for parallel computations. As a first step in modularization, the new release features an internal structural separation of coefficient rings and polynomial rings. This allows for a flexible integration of new coefficient rings.

SINGULAR 4-0-0's list of new functionality and significant improvements further extends that of the 3-1-6/7 prerelease series.

New functionality

- de Rham cohomology of complements of algebraic varieties ([Section D.5.3 \[deRham_lib\]](#), [page 1431](#))
- Gromov-Witten numbers of elliptic curves ([Section D.4.8 \[ellipticcovers_lib\]](#), [page 1068](#))
- classification of isolated complete intersection singularities in characteristic 0 ([Section D.6.8 \[classifyci_lib\]](#), [page 1666](#))
- parametrization of orbits of unipotent actions ([Section D.5.10 \[orbitparam_lib\]](#), [page 1463](#))
- F5-like Groebner basis algorithm ([Section 5.1.140 \[sba\]](#), [page 259](#))
- element-wise application of functions to data structures ([Section 5.2.1 \[apply\]](#), [page 290](#))
- support for debugging libraries ([Section 3.9.1 \[ASSUME\]](#), [page 68](#))

Improved functionality

- Groebner cover for parametric ideals ([Section D.2.4 \[grobccov_lib\]](#), [page 818](#))
- normalization of affine rings ([Section D.4.23 \[normal_lib\]](#), [page 1185](#))
- classification of real singularities ([Section D.6.19 \[realclassify_lib\]](#), [page 1750](#))
- GIT-fans ([Section D.13.3 \[gitfan_lib\]](#), [page 2093](#))
- algebraic/transcendental field extensions
- [Chapter 7 \[Non-commutative subsystem\]](#), [page 318](#)
- an abstraction layer for parallel computations ([Section D.2.7 \[parallel_lib\]](#), [page 885](#))
- run-time loading of supplementary kernel code ([Section A.1.9 \[Dynamic modules\]](#), [page 709](#))
- interpreter language support for name spaces ([Section 4.16 \[package\]](#), [page 119](#))

Availability

SINGULAR is available as source code and for Linux, Mac OS X, Windows, FreeBSD and SunOS-5.

8.2 Singular 3 and Singular 4

The purpose of this section is to describe new features and changes between Singular 3-1-7 and Singular 4.* (formerly known as Spielwiese) both for developers and Singular users. In what follows we will refer to the systems as Singular 3 and Singular 4.

8.2.1 Version schema for Singular

SINGULAR version is of the form a.b.c.d which may also be written as a-b-c-d where a,b,c and d are numbers:

- a is changed with major, incompatible changes
- b is changed with incompatible changes (of some commands/libraries)

c is changed with compatible changes (i.e. new commands, extended options, new algorithms, etc.)

d is changed with each release (i.e. with bug fixes, etc.)

SINGULAR does also have "unofficial" build originating from a code version between "official" version: such builds display "Development version a.b.c" in the header while "official" versions show "version a.b.c". Also the manual describes version a-b-c. To get the complete version number, use `system("version");` or use `SINGULAR_VERSION` in C.

8.2.2 Notes for Singular users

Coefficient rings

To allow for easy integration of new coefficient rings into Singular, the the way coefficient rings are being handled has been redesigned.

In general, the user syntax has not changed, however there are some changes in the behaviour of Singular:

- setting `minpoly` results in changing the current coefficient domain and clears all previously defined variables of that ring
- Minor changes in the output of coefficient ring description. Moreover the output of elements of certain rings has been improved (for example, reals).
- Algebraic and transcendental extensions of rationals and finite fields have been reimplemented. In particular, the heuristics for clearing denominators and factoring out content have been changed. In some cases this leads to a different, mathematically equivalent results of Groebner bases and related computations. For example a Groebner basis element may differ by a unit.
- Most notably, due to the redesign of the coefficient rings, if the user sets the minimal polynomial all variables dependent on the current ring are deleted.

Ring-dependent options

Formally global Singular [Section 5.1.111 \[option\], page 234](#) now belong to individual polynomial rings. This includes:

- `intStrategy`
- `redTail`
- `redThrough`

Also the following settings now belong to individual (currently active) polynomial rings:

- `short`
- `minpoly`
- `noether`

Hence setting these options only affects the current ring. Be aware of this when switching between different rings, since the options affect the result of various computations (in particular Groebner bases).

Path names

- The tree structure of the binary Singular distribution has been changed. The typical tree now looks as show at <https://github.com/Singular/Singular/wiki/Sw-tree>

- Accordingly Singular search paths (where Singular searches for libraries, dynamic modules, etc.) have been changed. You can display them by calling Singular by `Singular -v`.
- currently, multi-arch installations of Singular 4 are not possible.

Library versioning

Due to switching from Subversion to GIT revision control system for the Singular source code, library version variables (displayed when loading a library) have changed.

New orderings for modules

Now one can assign weights to module components, when defining a monomial ordering. For example

```
ring R = 0, (x,y,z), (am(1,2,3, 10,20,30,40), dp, C);
deg(x*gen(1));
↳ 11
```

will assign weights 1,2,3 to x,y,z respectively, and weights 10,20,30,40,0,0,... to components of any free module defined over R. This ordering will first sort by this weighted degree, then by dp on the ring monomials and then will give priority to the large component index.

Future benefits of Singular 4

The redesign of Singular will allow us to provide new features in the future, for example:

- Interpreter type for coefficient rings.
- User defined coefficient rings.
- Improved syntax for defining polynomial rings.

8.2.3 Notes for developers

There has been an intensive process of refactoring, redesign and modularization of Singular to facilitate easier maintenance and future development:

- Build System : automake, libfac has been integrated into Factory
- Removed MP (Multi protocol) in favor of SSI links.
- Separation/modularization into libraries and packages
- For easy integration of new coefficient rings, we defined a generic interface for coefficient rings and a supporting framework for making them accessible to the user.

In particular we have separated everything related to coefficient rings into a separate library `libcoeffs`. Dependency tree between restructured packages is shown at <https://www.singular.uni-kl.de/dox/singular.png>

In order to use `libSingular` as a C++ library, see [Section 8.3 \[libSingular\]](#), page 2649.

8.2.4 Building Singular

The user can build and install Singular with the following standard UNIX-like procedure:

- Download and extract the latest official source package (.tar.gz).
- Run the configure script, for instance, `./configure`.
- Build Singular by running `make`.
- Install Singular by running `make install`.

In contrast to Singular 3, there are now many more configuration options.

All possible options for configure can be seen by running the configure script with option `--help`. On a multicore compute consider running make with the option `-j [cores]`.

8.2.5 Side-by-side installation

Due to choosing paths according to FS standards it is no longer possible to have a side-by-side installation of different Singular versions or versions for different architectures.

8.3 libSingular

libSingular is the C++-library version of SINGULAR.

Singular/libsingular.h is the main include file, `-lSingular` the link parameter, lib/pkgconfig/Singular.pc provides all parameters in the pkgconfig format.

It contains all parts of SINGULAR with the following exceptions:

1. memory allocation functions for GMP (see `mmInit` in Singular/tesths.cc)
2. signal handlers (see `init_signals` in Singular/cntrlc.cc).

At least a handler for SIGCHLD must be installed for the commands [Section 5.1.170 \[waitfirst\]](#), [page 287](#), [Section 5.1.169 \[waitall\]](#), [page 286](#) and the routines from [Section D.2.7 \[parallel_lib\]](#), [page 885](#), [Section D.4.16 \[modstd_lib\]](#), [page 1148](#), [Section D.4.23 \[normal_lib\]](#), [page 1185](#), [Section D.2.13 \[tasks_lib\]](#), [page 959](#).

If the child was started by libSingular the handler has to call `sig_chld_hdl` from Singular/links/ssiLink.cc or implement something similar (call `siClose(1)` for ssi links).

3. error handlers for factory, NTL (see `init_signals` in Singular/cntrlc.cc).

8.4 Download instructions

SINGULAR is available as source and binary program for most common hard- and software platforms. Instructions to download and install SINGULAR can be found at

<https://www.singular.uni-kl.de/index.php/singular-download.html>.

Sources of release versions of SINGULAR are also available from our FTP site

<ftp://jim.mathematik.uni-kl.de/pub/Math/Singular/src/>.

or

<https://www.singular.uni-kl.de/ftp/pub/Math/Singular/src/>.

8.5 Used environment variables

SINGULAR needs to find some files (dynamic modules, libraries, help files). Usually they are found relative to the location of the (main) executable (after following symlinks). This can be changed by setting the following environment variables.

SINGULAR_EXECUTABLE (should usually not be set)

the complete filename of the main executable, usually derived from the command line (inspecting also PATH, following symlinks).

If SINGULAR_EXECUTABLE cannot be found, `$prefix/bin/Singular` is assumed.

For libSingular: SINGULAR_EXECUTABLE is set to the argument of `siInit` (it must exist).

SINGULAR_BIN_DIR

the directory of the main executable, usually derived from `$SINGULAR_EXECUTABLE`

SINGULAR_ROOT_DIR

the root of the singular tree, default: `$SINGULAR_BIN_DIR/..`

SINGULAR_DATA_DIR

the root of the singular data files, default: `$SINGULAR_BIN_DIR/./share`

SINGULARPATH

the directories for libraries and optional dynamic modules (separated by `;`), default:

`$SINGULAR_DATA_DIR/singular/LIB`

`$SINGULAR_ROOT_DIR/share/singular/LIB`

`$SINGULAR_BIN_DIR/./share/singular/LIB`

`$SINGULAR_DATA_DIR/factory`

`$SINGULAR_ROOT_DIR/share/factory`

`$SINGULAR_BIN_DIR/LIB`

`$SINGULAR_BIN_DIR/./factory`

`$SINGULAR_BIN_DIR/MOD`

`$SINGULAR_ROOT_DIR/lib/singular/MOD`

`$SINGULAR_ROOT_DIR/libexec/singular/MOD`

`$prefix/lib/singular/MOD`

`$prefix/libexec/singular/MOD`

`$SINGULAR_BIN_DIR`

SINGULAR_PROCS_DIR

the directories for dynamic modules (separated by `;`), default:

`$SINGULAR_BIN_DIR/MOD`

`$SINGULAR_ROOT_DIR/lib/singular/MOD`

`$SINGULAR_ROOT_DIR/libexec/singular/MOD`

`$prefix/lib/singular/MOD`

`$prefix/libexec/singular/MOD`

SINGULAR_INFO_FILE

`singular.info`, default: `$SINGULAR_DATA_DIR/info/singular.info`

SINGULAR_IDX_FILE

the help index, default: `$SINGULAR_DATA_DIR/singular/singular.idx`

SINGULAR_HTML_DIR

the directory of the manual as html files, default: `$SINGULAR_DATA_DIR/singular/html`

SINGULAR_URL

the URL of the manual, default: `https://www.singular.uni-kl.de/Manual/`

The effective list of directories/files can be printed by `Singular -v`, see [Section 3.1.6 \[Command line options\]](#), page 19.

Depending on the used functions, these environment variables apply also to `libSingular`.

8.6 Unix installation instructions

Install binaries: <https://www.singular.uni-kl.de/index.php/singular-download/install-linuxunix> or build it yourself:

Install the necessary packages:

```
libtool
gnu make
gcc, g++
libreadline
gmp, mpfr
ntl
libcdd
```

Install flint 2.5 (or newer): `./configure --with-gmp=/usr --prefix=$HOME/tmp`
`make && make install`

Install Singular `./configure --with-flint=$HOME/tmp --enable-gfanlib --`
`prefix=$HOME/Singular4`
`make && make install`

(\$prefix/bin/Singular is the main executable)

(optional) install 4ti2

(optional) install surf/surfer

(optional) install normaliz 2.8 (or newer)

See also <https://github.com/Singular/Singular/wiki/Step-by-Step-Installation-Instructions-for-Singular> which includes instructions adapted for debian and fedora based systems.

8.7 Windows installation instructions

Singular relies on Cygwin as its environment under Windows. There is a 32bit and a 64bit version of Cygwin.

<https://www.singular.uni-kl.de/index.php/singular-download/install-windows.html>

8.8 Macintosh installation instructions

Installation of the provided binaries <https://www.singular.uni-kl.de/index.php/singular-download/install-os-x.html>

If your Mac refuses to open Singular because of an "unidentified developer": Open System Preferences. Go to the Security & Privacy tab. Click on the lock and enter your password so you can make changes. Change the setting for 'Allow apps downloaded from' to 'App Store and identified developers'.

You may also check <https://support.apple.com/en-en/guide/mac-help/mh40616/mac>
